3035.—**Annuals for Spring.**—As this is about the time for sowing hardy annuals for spring blooming, I should like a select list of such, and to be informed of the aspect, nature of soil, mode of sowing, and such particulars as will insure success.—J. G.

3036.—**Small Standard Apple Trees.**—Can any one tell me of any varieties of Apples that when grafted on the common stock and full grown would form small standard trees? and might a graft on the Paradise stock itself grow to 5 ft. or 6 ft., and then take a graft or bud, so as to form a good standard tree? Would the above apply also to the Pear on the Quince stock?—J. J.

3037.—**East Lothian Stocks.**—Early in the month of March I sowed some East Lothian and Intermediate Stocks in a cold frame. Planting them out 1 ft. apart each way, they have grown to be splendid plants crowded with laterals, but they do not yet show any signs of blooming. Would mats stretched over poles save them during the winter? and if so saved, would they bloom next summer? Our winters are very severe.—OLD SUBSCRIBER.

3038.—**Road Sand for Striking Geraniums in.**—I have been told that road sand is such an excellent thing for striking Geraniums in, that although I had always been very successful without it, I gave it a trial, the result being I have not struck one cutting out of one hundred; they rot in a few days. I put 2 in. of this sand on an ordinary good light garden soil, lightly forked it in, made the surface smooth, and dibbled the cuttings in. In the course of a week three-parts of them rotted. Thinking the first batch was too succulent, I put others in, but they went off as before. I resolved to take the whole of them up; I had not a sound cutting in the lot. I also put a portion of this sand with the mould. I prepared for striking Verbenas and Mesembryanthemums and the like with no better success. I come to the conclusion that the road sand was the cause of my failure, but not liking to condemn it myself, I should feel obliged to any practical man to give me his opinion whether road sand is injurious or beneficial for such purposes.—B. T.

3039.—**Berries for Winter Decoration.**—Can any one tell me how to preserve berries, such as those of Pyracanthus and Mountain Ash, so that they may be used during the winter for wearing in the hair, or putting in vases? I have tried putting sealing-wax on the ends, but that method was not successful.—CEDAR.

3040.—**Unfruitful Grape Vine.**—I have a Grape Vine trained against a wall which faces the west. It has never produced any fruit although it has been planted several years; the soil is gravelly. Instructions how to proceed with it would be gratefully received?—EVA.

3041.—**Plants not Flowering.**—This is the second season I have had Phædranassa chloracea, Hæmanthus punicens, and Hedychium Gardnerianum, and I have only succeeded in producing leaves. Can any one tell me the cause of my failure? What kind of soil suits them best? and what are the conditions necessary for success?—G. WATSON.

3042.—**Geraniums and Fuchsias not Flowering.**—Why is it my Geraniums do not flower? and why do the buds of my Fuchsias drop off before arriving at maturity? I have tried them with plenty of water; then I tried watering them every other day, and I have tried rich weak manure water twice a week, and I have repotted them, but with the same result. I cannot get them to flower; the buds always drop off.—N. W.

3043.—**Welsh Names of Hornet, Humble Bee, Wasp.**—Would some Welsh gentleman kindly give us the popular Welsh name of each? Our English-Welsh dictionaries do not give me satisfaction on the subject.—JOHN DAVIES.

3044.—**Lost Roses.**—Will any one kindly tell me where I can procure a root of Rosa sulphurea, the yellow Cabbage Rose, also Mogador, as for some time past I have sought for these Roses in vain?—HARTSIDE.

3045.—**Fuchsia Buds Dropping off.**—Can any reader inform me the reason why the buds of a Fuchsia drop off? The plant is kept in a room, the windows of which are open all the day, and the roots are well supplied with water.—JENNIE.

3046.—**Overgrown Wall Trees.**—Can any one advise me with respect to a Plum tree. It has evidently grown wild for some time, and is now in a very bad condition. Instead of branching out on either side from the stem it is nearly devoid of side branches, the chief growth being situated on the top of the stem and overhanging the wall.—E. H.

3047.—**Insects in Manure Tanks.**—I have a tank for the purpose of collecting house refuse liquid, and I find that it is getting full of insects about ½ in. in length, having a pointed black snout fully ½ in. long, and as other insects may also infest me, I ask the aid of any reader to enable me to exterminate them.—G. M.

3048.—**Woodlice and Earwigs.**—Can any one tell me how to eradicate these pests from the greenhouse?—F.

3049.—**Insects in House Slops.**—Exposed to sun and air for some time, this is said to form a good liquid manure for plants. After rain, however, it becomes infested with some obnoxious living creatures which it would be agreeable to know how to get rid of; they remain actively alive when turned out of the tub on to the hot ground. How are they to be destroyed? and by what means can their formation be prevented?—J. J.

3050.—**Soluble Phenyle.**—I would like to know where I could obtain the fluid known as Little's Soluble Phenyle, of which the ingredients were stated to be a distillation of tar similar to creosote and pure oil, also cost per gallon. I have applied to several druggists, but they seem to know nothing about it?—J. M. G.

3051.—**Drying Tobacco.**—A friend has written to me from the Cape of Good Hope asking for information respecting the growing and drying of Tobacco. Can any one tell me where any information can be had? Are there any publications on this subject? -GOOD HOPE.

3052.—**Daisies on Lawns.**—Will some one afford me a little information as to the most effectual way of destroying Daisies on lawns?—H. M.

3053.—**Grapes not Ripening.**—Will some one give me some information as to the cause of the small stalks on which each Grape is grown turning brown, and so causing the Grapes to become sour and not colouring well?—A. A.

POULTRY.

Chickens.—Early broods will now have arrived at an age which enables their owner to distinguish those worth keeping from the second-rate ones. The former should be forced on to maturity as rapidly as possible before cold weather sets in. Avoid over-crowding; weed out inferior birds by killing and selling; it is astonishing what good effect this will have on the remainder by affording more range and exercise. Often a brood is kept in the same small run week after week, regardless of the fact that the birds have increased ten-fold or more in size since they were first put there. This must result in weakly specimens, with germs of disease ready to burst forth at the slightest provocation. Separate the cockerels from the pullets, especially with precocious breeds such as the Hamburgh or Leghorn. Do not be afraid of killing for the table, as although the birds are not what they would be in a month's time as regards size, yet they are excellent eating, and it is affording the others a fair chance to grow into fine, useful fowls. Be not in a hurry to provide perches for the youngsters at night; it is a fruitful source of crooked breasts and other deformities. Better let them rest on the floor of the house, on which a good layer of dry earth is spread and renewed often. Let all doors and windows remain open day and night, if possible, until the weather gets cold, which will not be for many weeks yet. Supply plenty of old mortar and lime; chickens require it as well as old birds. Bone-dust or meal is an excellent addition to the soft food, as is also a little sulphate of iron in the drinking water, or, better still, Walton's tonic paste. Remove all diseased birds as soon as discovered, as chickens are more liable to infection than old fowls. Keep up the supply of green food where grass is not obtainable; it is as requisite as good Corn.—ANDALUSIAN.

Rearing of Poultry.—Can any one recommend me a reliable book on this subject?—S. R. T.

Spanish Pullets.—I should feel obliged to any reader who would kindly inform me where I could purchase a few really fine, healthy, pure-bred birds of the above variety, with probable price per couple? Must be of good laying stock.—NORTHAMPTON.

Fowls for Laying in Winter.—Do Houdan hens lay as well in winter as Brahmas? I consider them a more delicate bird for the table.—CONSTANT READER.

Broody Hens.—How can I cure hens of wanting to sit now it is too late for hatching?—J. H. B.

Books on Poultry.—Can any one recommend me the most reliable books on rearing poultry?—S. R. T.

Parasites in Chickens.—These can often be got rid of with Keating's powder; but unless fowls are provided with a good covered dusting place, filled at least 6 in. deep with ashes and dry earth, they are always tormented with insects.—B.

Disease in Poultry.—In answer to "M. J." in your issue of Aug. 21, I beg to say that whenever I notice any signs of illness in my poultry, such as refusing food, drooping wings, &c., I at once administer a teaspoonful of castor-oil, poured down their throats from the bottle neck. This has a magical effect, the patient invariably being ready for its breakfast next morning.—E. P.

Houdan Fowls.—Where can I get birds of this breed about twelve months old?—E. M. W.

Aylesbury and other Ducks.—I keep Muscovy ducks. I also have a desire to keep a few white Aylesburys. I cannot keep them separate, and I am told I may let them run together, but that they will not mate. Is this so?—ALPHA.

Salt for Poultry.—Is salt injurious to poultry?—WOOD B.

Best Fowls to Keep.—Which is it best to keep: two Houdan cockerels, or one Houdan and one Minorca, with about thirty pullets?—WOOD B.

Thorough-bred Minorcas.—What are the specialities of a thorough-bred Minorca cockerel? I have one with a comb like that breed, but with no tail.—WOOD B.

Vermin in Fowls' House.—Can any reader inform me the best way of getting rid of lice from the fowls' house? I have lime-washed it but that does not seem to do any good.—W. E. B.

BEES.

MY EXPERIENCE IN BEE KEEPING.

PROBABLY my experience in bee keeping will be interesting to many of your readers. A friend of mine presented me with a large straw-skep, twelve months ago last September, containing a stock of bees from which he had abstracted all the honey and comb; of course they could not obtain a particle of honey that winter, so that I had to feed them with syrup. From that skep I have now six strong stocks in good condition to stand the next winter, and have also taken about 40 lb. of honey. This, considering the weather we have had, I think to be fair work; and although I have not kept a strict account of my expenditure, I am certain I could now sell my bees and make a good profit. I find that judicious "feeding" is the first consideration in bee keeping; and a good hive the second. But as bees cannot be fed without they are hived, I will commence with the latter. When I found last spring that I had wintered so well the first stock of bees, I began to look about me for the best hive to adopt, and with this view I consulted the American and English bee journals, the catalogues of the leading manufacturers, and all works on bee culture that I could lay my hands on. I also paid a visit to the exhibition of the British Bee Keepers' Association at South Kensington—the result of all this was that I made up my mind to use a bar frame hive in some shape or other. For the cheapest I obtained a makeshift Woodbury hive as a pattern; this cost me 4s. 6d. and 2s. for carriage. I found that would not pay, so I tried to make one myself, and succeeded to my own satisfaction; but when I came to utilise the hives I found there was something wrong about them, the bees did not half fill them with comb during the summer, and I had the greatest difficulty in keeping them through the winter. So I consulted a mechanical friend who has a "bee in his bonnet," and we came to the conclusion that the passage for the bees round the end of the frames was were the mischief lay. The bees instinctively leave a space for the passage of air round the end of the combs, but will not adopt that provided for them round the end of the frames, and waste their time and energy in trying to fill it up. This led us to adopt a frame which, I think, will be the most practicable, and as they cost only 1s. 6d. per dozen, they will be within the reach of all. They are made to fit into an ordinary Woodbury hive; they require neither nails or block to fit them together, and a few of them placed side by side, a piece of board (with entrance cut out) at back and front, and the whole pasted together with brown paper, forms a complete hive for 1s. 3d. The frames can be used on the Stewarton, Combination, Italian, or any other principle, with supers, nadirs, or ekes. I have tried them in every way, but the form I like best is a hive about 2 ft. long by 14½ in. wide, with entrance at end, in which I place about nine frames for a brood nest, then a glass dummy board with queen-excluding slit cut out of bottom, giving access to bees to other frames placed behind it; the bees store the honey in the latter, from whence they can be easily taken out and emptied by a slinger, which can be made by an ordinary tinker for a couple of shillings. The frames have another advantage: when fitted in hive with dummy board, there will be a dead air space on three sides, thus requiring less outer covering.

BAR FRAME.

HOME PETS.

King and Queen Parrots.—The most likely place to get the female would be at one of the many shops in Whitechapel and Radcliffe Highway on the arrival of a ship, or advertise for one. They will live out-of-doors in an aviary, and breed if they are not molested by other birds. It is desirable to keep only quiet birds with the king if you wish for any success in breeding. They are natives of Australia, in which country their favourite food is Maize. Feed as directed in my previous article. As to the other smaller parakeet, description is not sufficient for me to tell its name.—A. D'A.

Keeping a Cuckoo.—This is a very difficult matter; at the same time I should like to buy one, as I have been on the look-out for one for a particular purpose.—S. H.

—— I took a cuckoo out of a robin's nest last year, and succeeded in keeping it alive till the middle of November. I fed it on caterpillars as long as I could find them, mostly those on Gooseberry bushes and Cabbages; when they failed I gave it raw meat, cut up into little strips; it preferred that which was soft and flabby. I fed it at first with the points of a pair of scissors, but afterwards it fed itself, and would drink, and once or twice bathed in a saucer placed in its cage. It soon became quite tame with me. It seemed to feel the cold very much, though kept in a room with a fire, and I think that was the cause of its death.—C. C. F.

Thrush Losing its Song.—I have a thrush which has sung very well during the spring, but it gave up all at once its song. It seems quite lively and healthy. Would some kind reader inform me what to give it to make it sing again?—LEEDS.

GARDENING
ILLUSTRATED.

VOL. II.—No. 80. *SATURDAY, SEPTEMBER* 18, 1880. PRICE ONE PENNY.
REGISTERED FOR TRANSMISSION ABROAD.

DOUBLE-FLOWERED CHERRIES.

THESE rank among the most beautiful of hardy spring and early summer-flowering trees and shrubs, being loaded with flowers varying in colour from bright red to snowy whiteness; the flowers are generally produced upon small spurs from ½ in. to 2 in. in length, which arise mostly from the sides and ends of the two or three year or older branches, and, like all double flowers, last much longer in perfection than single ones. The double Cherries will grow in any firm loam soil, and in towns they flower profusely in early spring. Dwarf bushy plants of double Cherries grown in pots are handsome objects for conservatory or greenhouse decoration. They are easily grown, only requiring to be potted in firm loamy soil, placed out-of-doors plunged in ashes in a sunny situation during summer, and taken into the greenhouse in autumn, when they will flower some weeks before those out-of-doors open their blossoms. There are various species and varieties of double Cherries, among which the following may be mentioned as the best: Saint Julian Cherry (Cerasus Juliana floribus-roseis).—This forms a tree from 20 ft. to 30 ft. high, with the branches ascending when young, and when in the adult state hardly spreading; the leaves are smooth, and appear along with the flowers; the latter are semi-double, large, and of a pale rose colour when fully expanded, but of a deep red or crimson when in the bud state. It is a very handsome kind when in flower, and all the cultivated varieties named Geans in England, and those named Guignes in France, belong to it. Common Double-flowered Cherry (C. Avium multiplex).—This is the old double-blossomed Cherry of gardens; it forms a tolerably large tree, with rather a dense, roundish head, loaded in May with drooping double white flowers. It is known in some parts of England as the double Carone Cherry. There are two double-flowered forms of this kind—one with semi-double flowers and the other with all the stamens changed into petals and the pistils into green leaves more curious than ornamental. Double French Cherry (C. duracina fl.-pl.).—This forms a robust tree 30 ft. or 40 ft. high, which in May becomes loaded with festoons of large, drooping, snow-white flowers. It is the double form of the Bigarreau Cherry. This is the finest of all the double-blossomed Cherries, and resembles in every respect the common Bigarreau. Yung-To or Chinese Cherry (C. serrulata).—This forms a robust shrub or small tree 6 ft. or 8 ft. high, with stout, divaricate branches, having but few laterals. The leaves are moderately large, pointed, and quite smooth. The flowers, which are semi-double, are produced in bunches on the two or three-year-old branches; they are white when first they expand, but before they fade become tinged with pink. It is a very ornamental kind, and well suited for planting in the front of shrubberries. It flowers in April, and is perfectly hardy. Japan Cherry (Cerasus japonica multiplex).—This is a very handsome, neat, dwarf bush, from 2 ft. to 4 ft. high, with ovate, pointed, smooth, shining leaves; the naked shoots are slender, of a purplish colour, and

DOUBLE WHITE CHINESE CHERRY.

numerous ; the flowers, which are pale blush, are produced in great profusion from March to May ; the fruit is round and about the size of a Pea. It is a native of Japan, and as it flowers early is liable to get injured when planted in the open border ; it is best planted against a south wall, where it forms a very beautiful object. There is a variety of this kind, the dwarf, double white-flowered Japan Cherry, a kind rather more robust in habit and rather larger, and more double, the flowers being pure white. It is a very handsome and distinct variety, found in the north of China, but has its blossoms injured by the spring frost when planted in the open border. Three-lobed leaved Chinese Cherry (C. triloba).—This forms a low bush 3 ft. or 4 ft. high, and produces early in spring, before the leaves appear, fine, large, double, pale pink blossoms ; the leaves are somewhat large, wrinkled, and of various shapes, some being broadly oval, with three acute lobes towards the apez, while others are oval, and free from any lobes, but they are all coarsely serrated on the edges, and bright green. It is a native of the north of China, and quite hardy, but suffers from the spring frost when in bloom and planted in the open border. It has been named Amygdalopsis Lindeyi by a French writer. It is a very beautiful shrub, but one which gets injured by the spring frost when in flower.

CLEMATIS LANUGINOSA AND ITS VARIETIES.

THE Clematis is now acknowledged to be one of our most valuable and beautiful garden plants. The rich shades of blue and purple which so many of the varieties of the Jackmani section possess are extremely effective, especially in the case of highly developed specimens. Whether trained to poles, over rustic archways, or allowed to scramble irregularly amongst the surrounding vegetation, or made to cover the surface soil with a dense mass of flowers and foliage, they are equally beautiful and effective, and deserve all the pains which may be necessary to ensure their well-being. Not less beautiful, although not quite so showy, are the varieties of the lanuginosa type. These are mostly distinguished by the large dimensions of the individual blooms and the delicacy of colouring which they display. The colours run mostly into shades of white, blue, and lavender, some of the white kinds, which are either suffused or striped with lavender, mauve, or violet, being very attractive. It is, however, when seen in combination with the dark-flowered varieties that their peculiar charms receive due recognition. I do not know of anything more strikingly effective than the contrast which such kinds as Jackmani, rubro-violacea, lanuginosa nivea, and l. candida afford when planted in close proximity. C. lanuginosa itself, although a beautiful species, never attained universal popularity in English gardens, a fact which may be attributed to a lack of vigour of constitution. In some places where the soil is warm and well drained it grows with freedom and flowers profusely, but it is only in such situations that it should be planted. Where the natural staple is cold and damp it is apt to succumb to the rigour of a severe winter. This defect is not so strongly marked in its hybrid varieties, which, when planted with care in suitable soil and otherwise liberally treated, increase with each succeeding year in luxuriance and beauty. In any case, however, they cannot be said to be quite so strong and robust as the varieties of the Jackmani, Viticella, and patens groups, and are therefore not so well adapted for planting in the near vicinity of shrubs, trees, or amongst strong vegetation. Nor do they rush away into growth at such a rapid rate when newly planted, but require one or two seasons' careful culture until they get established, when they reward such care by a lavish display of bloom, lasting in beauty generally until cold weather sets in.

The rough and ready mode of pruning found to answer in the case of the Jackmani and Viticella types will not do for the lanuginosa varieties. The knife in their case must be used with discretion ; only the weakly shoots should be cut away, and the strong growths must be shortened back merely, as it is from shoots made from the well-ripened wood of the preceding season that flowers are produced. An injudicious method of planting combined with a bad system, or more frequently perhaps no system at all, of pruning has caused many to fail, or at any rate has hindered them from obtaining a just conception of the merits of this particular section of the Clematis family. Even where the most unfavourable conditions in the matter of soil exist it lies in the power of the grower to counteract them, and to ensure a free tolerably strong development even the first year of planting. A very sandy parching soil offers no particular difficulties. It has merely to be deeply stirred, richly manured, and well mulched and watered during the growing season, and all will go well. In such soil the root fibres will be in no danger of suffering from excess of moisture in the winter. If at the same time a little sound loam can be added there will remain nothing more to be desired.

Where the natural staple is of a cold, retentive character the case is very different, and a very careful preparation must be made, or, especially in the case of stiff, undrained clays, but poor results will be obtained. There are, however, always ways and means of rendering the most tenacious and impermeable of soils mellow and free. These means are sufficiently well known to practical growers, but for the benefit of the uninitiated I may mention wood ashes, leaf-mould, river sand, mortar, and brick rubbish, each and all of them capable of imparting to a stiff, retentive soil the desired amount of porosity. Throw the natural soil out before winter arrives, or, better still, do so in the summer, so that sun and air—both of which do their work better than frost and wind—may thoroughly sweeten and bring it into a mellow, workable state. Incorporate with it such materials as may be procurable and plant about the middle of October. In March mulch them with 3 in. or 4 in. of manure ; water when necessary, and there will be but little fear of them not making good growth. Clematises are grown for sale in small pots, and it often happens that the ball of soil is somewhat hard. Many do not trouble to loosen this body of earth, but plant it entire, with the consequent effect that it becomes dry, and, remaining so, the roots cannot get away from it into the new soil. The plant, therefore, starves in the midst of plenty. Plants thus set in the earth are generally years before they make a free start. Every particle of the old soil should be worked gently away and the roots spread out upon the prepared compost, when, finding themselves at home, they immediately form fresh feeders, and are in the best of condition for breaking anew into life when the season arrives for them to do so.

A short time since allusion was made in the columns of *The Garden* to the merits of lanuginosa nivea, a white flowered kind, the blooms of which at times when first expanded exhibit a faint tinge of lavender, but which quickly bleach to a snowy whiteness, thus justifying its varietal designation. When seen in the form of well-developed masses, this variety is very effective, especially so when trained to poles or over a short trellis, and backed up by evergreens. The most effective white flowered kind is, however, found in l. candida, the individual flowers of which are large, though not so purely white as those of nivea. This is a grand variety, and the best of the light flowered kinds for bedding purposes, being of robust growth and a free flowerer. Amongst other light coloured varieties may be mentioned Otto Frœbel, having immense grayish-white flowers ; Lady Caroline Neville, French-white with mauve bands ; and Mrs. Moore, white, suffused with mauve. Of the blues there are Aureliana, very attractive ; Beauty of Surrey, light grayish-blue ; Gem, lavender-blue ; and Robert Hanbury. Other kinds, including shades of mauve, lavender, and violet, consist of Lawsoniana, La Mauve, Mrs. Hope, Symesiana, and Ornata. J. C.

A Well-grown Virginian Creeper.—It may interest some of your readers to know there is an Ampelopsis Veitchi planted at the back of one of the houses in Wilson Road, Camberwell, about twelve years since, that had climbed without support at any time to the roof of the house three or four years ago, and, having been cut away from the gutter, has covered the backs of four houses in the row, each about 18 ft. wide. The aspect is N.W., and it was planted in turfy loam in a corner that had been filled in after building with virgin soil out of the foundations of the houses. The main stem is about 2 in. in diameter. It can be seen from Camberwell Churchyard.—E. B.

VEGETABLES.

HOW TO GROW BRUSSELS SPROUTS.

THE Brussels Sprouts is undoubtedly one of the best and hardiest of our winter Greens, and ought to be found in every cottage garden in the country. Although nearly related to the Savoy, it is superior to that kind of Cabbage both in flavour and productiveness, and is at least quite as hardy. In the severe winter of 1860-61 I saw several instances where the Savoy had succumbed to the severity of the weather, while the Brussels Sprout had withstood it with comparative impunity. There are several varieties of it named in seedsmen's catalogues, but I think it is at least doubtful if they are really distinct. No doubt much has, and may still be, done to improve it by persistently carrying out a system of selecting seed from the best and most prolific plants only, and I do not know any vegetable that will better repay any extra care or trouble incurred in carrying this matter out in a thoroughly practical manner.

Sowing.—In the north and cold wet districts generally, to have Brussels Sprouts in season from October to March, the first sowing should be made in October. Sow thinly on a warm south border, and when the plants come up thin them out to prevent them drawing each other up weakly ; the thinnings may, if necessary, be pricked out. In October all seeds of the Cabbage tribe vegetate with the greatest certainty, and there is a strength and vigour about the young plants that is often absent from those raised from seeds sown early in spring. Whenever circumstances have prevented autumn sowing it is highly desirable, if the means are at hand, to sow a few seeds in a box in some spare corner under glass early in February, not necessarily in a warm house, as the plants will come up weakly, but in some cool airy structure, where they can be easily protected from the attacks of the many enemies to which early-sown seeds in the open air are liable. There is, I think, no question that if Brussels Sprouts were sown earlier, and had, consequently, a longer time for growth, the result would be satisfactory. Sow again in the open air in March and also in April for use in spring.

Planting.—The first plantation should be made early in May, in order to give the plants time to attain their fullest development by October or November, and as they should, when full grown, be at least 3 ft. high and stout in proportion, more space should be allotted to them than will be required for later crops ; 3 ft. will not be too much space between the rows, and 2 ft. from plant to plant. The demand must regulate the supply, but other plantations may be made at intervals when land becomes vacant till the middle, or, in warm situations, to the end of July, after which time—except, for instance, in a season like the present—they cannot be expected to attain a profitable size.

Soil.—In the matter of soil Brussels Sprouts are not at all particular, provided it is well and deeply cultivated and fairly manured. Poor sandy soil will require a heavy dressing of good manure, whilst lime and burnt clay may be beneficially applied to cold clayey land in preference to rank manure just previous to planting, which would have a tendency to produce gross open Sprouts instead of the close medium-sized buttons so much appreciated. Plant the successional crops as far as possible in the different aspects—even altering the direction of the rows will make some difference ; and a few should, if possible, be planted on the north side of a wall, fence, or screen of some kind. Frequent stirrings of the soil, general clean culture, and removing decaying leaves add to their growth and cleanly appearance, and ought to be insisted on.

Earthings.—As regards earthing up the stems, I have grown them, both with and without that assistance, with much about the same result. In windy places I should certainly recommend earthing up, in order to enable them to resist wind power; but as Brussels Sprouts, unlike Cabbage or Broccoli, bear all up the stems, it is not desirable to bury them to any great depth beyond giving them necessary support. Do not cut out the Cabbage-like heart from the centre of the plant till the crop is fit for gathering; and if a really good plant or two can be spared, save your own seed. The London market gardeners prefer, as a rule, stems of medium length, from which they think they get the hardest and best sprouts; with them, however, Brussels Sprouts are chiefly grown as catch crops. H.

Sowing Asparagus Seed.—Asparagus is propagated by seed, which may either be sown when ripe in October, or in spring; but the latter time is considered the best. It may either be sown on the ground prepared for the plantation, or in drills 1 ft. apart in beds of light, rich, sandy soil, and transplanted to a permanent position when one year old, which is by far the most desirable method. To get strong clean plants at one year old, and to save a year's strength, sow thin, and hoe out quickly after the plants are up, with a sharp one-hand 3-in. hoe, or otherwise thin the plants to 3 in. or 4 in. apart, taking care to select all the strongest plants to stand; thus very strong clean plants may be produced in one year. By keeping the seed-beds carefully hoed and free from weeds, the plants will be in fine condition for planting out the following spring; whereas, should they be neglected, it will take two years before they are as large as well-attended one-year-old plants. It is in consequence of this very common neglect that many cultivators labour under the impression that the plants must be two or three years old before planting, which is undoubtedly a mistake, for all good growers invariably plant one-year-old plants, and count on reaping a crop the third spring from the time of sowing. One pound of seed will produce about 3000 plants. In order to save seed, some of the finest shoots which push in the early part of the season from certain crowns should be allowed to run to seed. These should have the full benefit of exposure to light and air; and as they advance in growth they must be firmly staked to prevent breakage by wind. When fully ripe, the largest and finest berries of the deepest red colour should be selected. They should then be carefully and gradually dried; or they may, after lying about ten days, be squeezed between the hands, and the pulp washed away; but by the former method they keep the longest.

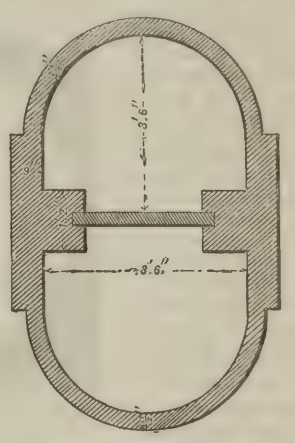
Cabbages.—A good piece of ground upon which to plant early Cabbages should now be dug over. Those sown in July will by this time be large enough to plant out. It is not well to manure heavily at the time of preparing the ground, for if much is put in for this crop, it has the effect of inducing over-luxuriant growth, which should be avoided. Although the Cabbage is very hardy, yet if the plants are forced into rank growth, they are often cut off in severe winters; consequently, it is better at this season to plant on soils that have been manured well for some previous crop. Ground where Onions have been grown, and which by this time will be cleared, will, if simply dug over, answer all purposes. In planting at this season, some distinction should be made in the different kinds; small-growing sorts, such as the Cocoa-nut, may be put in 9 in. apart in the rows, with intervals of 2 ft. between the rows. In the spring, as soon as they are at all fit for use, every other one can be taken out, leaving the remainder to develop more fully. Larger kinds, like Enfield Market, should be put in 1 ft. apart in the rows, in like manner taking out in the spring every alternate Cabbage; these larger growers should also have 2 ft. between the rows. When putting them out use a little soot and lime to each plant, for although this autumn-planted crop is not liable to suffer through clubbing in the way that the spring and summer plantings do, still these have the effect of keeping away slugs. In planting all the Brassica family, amateur gardeners are apt to err in either not putting them in sufficiently deep, or go to the other extreme of half burying the leaves. If the former mistake is made the wind blows them about in a way that does much mischief; and if too deep they do not do well. Whatever size the plants are they should be planted so that the bottom leaves will be on a level with the surface; this does away with the necessity for making the ridges too high in hoeing up. If the land is moderately dry it is a good plan to make with the hoe shallow trenches 5 in. or 6 in. deep, planting in the bottom of these. The advantage of this is that a portion of the soil in the so-formed intervening ridges can be drawn to support the plants before winter, and the remainder thus a little elevated acts as a protection from cutting, frosty winds, and in the spring can be put to the plants, still leaving them nearly on a level with the surface, thus enabling the whole of the roots to receive fuller benefit from rain than if placed on a high ridge that throws off the water. In ground that is insufficiently drained this plan will not answer for autumn planting, as the crop would be liable to suffer from too much wet. All the Cabbage family are surface-rooting, and do not push their roots down to any considerable depth; consequently, unless where the soil is extremely shallow, the above practice may with advantage be followed. For the summer crops this system can also be recommended, as it admits of the plants being earthed up sufficently without a ridge of any consequence being formed, and which, for the reason above stated, is better absent. When the space intended for the principal crop is filled, it is advisable to prepare a small corner in which to put some plants for a reserve; these may be pricked out about 6 in. apart, and will come in for filling up any gaps that may occur through the effects of a severe winter.

MY EXPERIENCE OF GARDENING UNDER DIFFICULTIES.

HAVING seen the experiences of many successful and unsuccessful amateurs in GARDENING ILLUSTRATED, and having derived much benefit from them, I thought a little of my experience of gardening under difficulties might be acceptable. My garden is situated next to some large smoky saw-mills in the metropolis of Ireland, and measures only 32 ft. by 24 ft. When I came into possession the soil consisted of loam with a large proportion of builders' rubbish. This I had put aside, and the contents of the ashpit put underneath as drainage, and then placed over it a compost of old manure from a spent hotbed, soil of the garden, and a few loads of fibrous (as we call it mountain) loam, thus making a fair soil of what I was told would not grow even weeds. I then put up three glass houses round three of the four walls bounding the garden, those houses forming one continuous house, each house being 6 ft. high behind, 2 ft. in front, 10 ft. broad, and 15 ft. long, the materials of which cost me about £4 2s. each house (of course, I did the work myself), being sixteen sash bars 14 ft. by 3 in. by 1½ in., rabbited, at 1s. each, 16s.; sheeting for front (the back was the wall) and for staging, 9s.; nails, &c., 4s.; the ends were the walls of the garden; the glazing of each house cost £2 14s., at 3½d. per square foot of 21-oz. glass glazed; I could have got it 1d. cheaper unglazed, but find it cheaper to have it glazed by tradesmen, thereby avoiding the cost of breakages during the glazing. Each of the sash bars make the roof, which is ¾-span, 3 ft. 6 in. behind, and 9 ft. 6 in. in front. I find this is a good angle to catch the sun's rays.

Having got up the houses, I commenced to stock them. To do this I obtained a list of cuttings of Pelargoniums, &c. I obtained the ones I thought would suit at 2d. per cutting, so that by autumn I had a stock of fairly-rooted plants for next year. The question now came, how was I to save them in an unheated greenhouse in the winter? To do this I purchased an old tubular boiler in good order and a quantity of rain-water pipes (these I find heat as well and are as durable, with ordinary caution, as the hot-water pipes, with the advantage of being much cheaper), and with these I constructed my heating apparatus, which kept up during the past hard winter a temperature of from 42° to 50° Fahr., and now I have a fine variety of plants of various kinds, as, for instance, 210 different varieties of zonal Pelargoniums, including the latest, twenty varieties of French and fancy Pelargoniums, besides several varieties of Fuchsias, &c.; all these I keep in the greenhouses for summer bloom. I also keep Cinerarias, Calceolarias, and Primulas for winter bloom along with Chrysanthemums. These I keep during summer on shelves fastened on the remaining wall of the garden until taken in in the winter. In the small piece of garden I chiefly cultivate Stocks, Asters, Phlox Drummondi, Golden Feather, Lobelia, and Pansies. These I find to do very well, with the exception of the Pansies, which drop off soon after blooming, the cause of which I would like to know. All my plants are grown in 6-in. pots and smaller sizes. When pot-bound I give them weak guano water (about a tablespoonful to the gallon) but twice weekly; by this treatment they do wonderfully, the trusses being very large, and the foliage fine and healthy. I shall be happy to give any of my fellow readers of GARDENING any information they require to the best of my ability. NELLA NHOJ.

Manure Tank.—I submit for the benefit of your readers a plan of a manure cistern given to me some years ago by an architect. Cesspool to be formed low enough to give a rapid fall to drain pipes, 7 ft. in length, 3 ft. 6 in. wide, and 8 ft. deep. 9-in. sides built in mortar and lined thoroughout in cement, bottom brick on edge. To have an overflow pipe from the compartment farthest from the house, to be fitted with a 6-in. flap trap. The middle part



Cistern for Manure Water.

to be fitted with 2-in. old Oak boards about 7 in. deep, placed in the grooves of brickwork for the water to drain off from the more solid parts, to be pumped up as required. An Oak frame and cover to be placed over the centre 2 ft. by 3 ft. in the clear. This will give access to both tanks. The other part to be covered over with rough flagging. An iron pump to be supplied and fitted to the Oak cover, to draw from the liquid tank. One side of the tank would hold about 500 gallons of liquid.

Glasnevin Botanic Gardens.—I would strongly recommend any of your readers who may be in Dublin during the next few weeks to pay a visit to the Botanic Gardens at Glasnevin. The fine weather has done wonders, and the display of colour out-of-doors is really magnificent. These beautiful gardens are admirably kept. They are easily reached from the city by the North Dublin tramcars, which pass the gates every few minutes, and there is no charge for admission.—W.

Notes from Devon.—In South Devon, little more than four miles from Dawlish, as the crow flies, frost cut down Clematis Jackmani to the ground the first week in June when it had made vigorous growth, and again on the 7th of August when it was just bursting into flower. On the second occasion, Runner Beans, Lonicera flexuosa, and Clematis Lady Londesborough were all struck in the same line, facing west, after a heavy westerly gale blowing all that day followed by a very brilliant starry night.—J. A.

—— I read much about a wet season and soaking ground, while in this part of Devon we have had a very dry spring and summer; so much so, that it has been next to impossible to

keep fresh plantings even of last October and March alive with any amount of watering. Potatoes are good all round, Early American Rose giving clear well-grown tubers of 18 oz. each. Late sorts are sound, but not doing so well, as we had twenty-four hours' rain about a month ago after a long drought, and this set them growing again, sending out at the same time fresh roots with tubers forming all round the crop Potatoes. The haulm of Magnum Bonum is at least 4 ft. high and ½ in. in diameter.—C. E.

HARDY FLOWERS FOR SMALL GARDENS.

JUDGING from what one sees in villa and small gardens generally, it would appear that their owners are but little acquainted with the wealth of hardy flowering plants now at our disposal for open-air decoration during the spring and early summer months. I feel convinced that the cheerless, flowerless aspect of such gardens during the early months of the year is to be attributed rather to defective knowledge than to a want of appreciation of the merits of those beautiful hardy flowering plants which bloom so freely and are so effective at that season. Allow me to remind your readers that no amount of brilliancy during the latter part of the summer and early autumn months can compensate for the almost complete dearth of colour which characterises the generality of small gardens, and which is too often observable in those of larger dimensions during the early months of the year. Whoever wishes to derive these enjoyments from his garden must create permanent interest therein, and this can only be accomplished by planting such flowering plants as come into bloom at different periods of the year, commencing with the Snowdrop and finishing with the Christmas Rose. Many have objected to hardy flowering plants on the ground that their blooming period is of short duration. This objection cannot, however, now hold good, for we possess at the present time a race of plants which unfold their cheerful showy blooms with the first glimpse of the spring sun, flower profusely and continuously throughout the summer, and are withal of such a hardy enduring nature, that they require no protection during the winter months, and demand but little cultural care throughout the flowering season. I allude to the so-called bedding

Bedding Violas.

Pansies and Violas, plants appreciated by some who have developed their capacities to the fullest extent, but which are, as a rule, too little known. What tender bedding plants, for instance, can surpass in beauty a mass of Cliveden Blue or Purple Pansy or Golden Gem Viola? Bedding plants may some of them bear away the palm for brilliancy, but for refinement and delicacy of colour they are on the whole inferior to these hardy subjects. The bedding Pansies are a most valuable acquisition to our gardens, as by their means we obtain, at a time when the ordinary run of tender bedding plants are being committed to the ground, glowing masses of colour, rendering the pleasure ground bright and gay long before these tender subjects recover from the checks and chills which they always more or less experience when placed in the open air. I would ask your readers to compare a garden in which a judicious employment is made of this pretty hardy flower with those entirely planted with the usual run of Geraniums, Verbenas, &c. On the one hand, we have brightness and beauty; on the other, flowerless plants, presenting for weeks a stunted, starved, unhappy appearance. Of both Pansies and Violas there are many varieties, some coming into bloom and creating a brilliant effect at a very early period, others more tardy of flowering, but producing a profusion of bloom throughout the summer. There are the Cliveden varieties, comprising a beautiful blue, a rich purple, a chaste white, and a bright yellow. Other varieties consist of Blue King, Cremorne (yellow), Dickson's Queen (pure white), Magpie (very pretty and distinct), and Chieftain (clear blue). The individual blooms of the Violas are not generally so large as those of the Pansy, but they are produced in such profusion throughout the summer, as to render well-grown masses highly ornamental. There are many varieties of this useful hardy flowering plant, comprising shades of yellow, blue, mauve, purple, as well as pure white. Bluebell is a highly recommendable kind, of dwarf, compact habit, flowering continuously from early spring till quite late in the autumn; Enchantress has mauve-coloured flowers, large and distinct; Loveliness is a beautiful variety, with purplish-violet flowers; and Mulberry is a distinct and effective kind, the name giving a true idea of the colour of the blooms. Of yellow, there are Queen of Yellows (a splendid bedding kind), lutea grandiflora major (pure yellow, very fine), and Golden Gem (not mis-named, and which is the most beautiful and effective of the yellow kinds). White Swan is, as the name indicates, a pure white kind; it has large flowers of good quality. Half-a-dozen kinds of Pansies and as many Violas, chosen with respect to variety and effectiveness, would alone suffice to render a garden gay and cheerful not only during the early months of the year, when the advent of sunny days brings with it a craving for bright flowers, but if afforded but a slight portion of that care indispensable to the welfare of tender plants, they will continue to flower vigorously throughout the summer.

The necessary attention consists in giving to each plant a good mulch of rotten manure, watering copiously in hot weather, and picking off decayed flowers, so that the plants do not exhaust themselves by seeding. It is at the same time advisable to put in a few cuttings every year about the beginning of June, dibbling them into a piece of nice fine light soil about 6 in. apart. These will form nice compact little plants by the autumn, and will serve to replace such blooming plants as have become exhausted or too straggling. I would indeed prefer to thus renew the stock every year, rooting up the old specimens about the beginning of October, and replacing them with these young thrifty plants, which, as a rule, produce finer blooms than the old stools. This yearly renewal will also enable the grower to well stir and well manure the soil, a point of great importance in the culture of these free and continuous blooming subjects. Those who may wish to do so may include in their collection a few of the best named show kinds, or they may sow anywhere during the summer months a little seed of the so-called fancy varieties, pricking out the plants when large enough to handle in a bed of prepared soil, and planting them in their permanent quarters during the autumn months. A bed of seedling Pansies is an interesting feature in a garden in the early part of the year, and when past its best may, if so desired, be replanted with Chrysanthemums, or a few good plants of Paris Daisy, or some seedling Petunias, which quickly grow into flowering plants, may be kept back for that purpose. The better way, however, supposing the Pansies to be planted in a bed in the Grass, would be to fill the centre with Lobelia fulgens. Japanese Anemones in mixed varieties, or herbaceous Phlox, which would form a telling feature at a later period, in which case the Pansies might remain as a bordering, or they might be replaced with Mignonette. For early spring flowering few things are more effective than

Myosotis dissitiflora, Silene pendula, and its dwarf variety. The latter plant is a gem, its extremely dwarf compact habit rendering it suitable for the smaller garden. I have remarked that the Wood Forget-me-not (Myosotis sylvatica) appears to be much more extensively grown than its congener M. dissitiflora. This I consider to be a mistake, as the latter is by far the most effective plant, either individually or in a mass. The first-named kind has a somewhat upright habit, and, after the first burst of bloom, presents a rather naked appearance, which becomes more marked as the season advances, a defect not observable in dissitiflora. The fact of M. sylvatica being of a more hardy nature may account for the preference shown it, but if young plants of dissitiflora are grown, they rarely sustain any material injury; whereas old stools, through holding a greater amount of moisture in the foliage, are generally destroyed when subjected to the vicissitudes of a severe winter. A slight protection of litter would, however, make all secure, and this plant displays such a beautiful shade of blue, as to render its presence almost indispensable in the pleasure ground, and warrants any small amount of labour which may be necessary to ensure its flowering in perfection. Both the Silene and Myosotis should be sown about the latter end of July in an open sunny situation. Prick out the seedlings when large enough about 6 in. apart, transplanting them to their winter quarters as early in the autumn as possible. Flowering bulbs of some kind should find a place in every garden. There are generally situations to be found in which some of the many beautiful varieties of Narcissus, Scillas, Crocus, Tulips, &c., may find a congenial home, where they may remain from year to year undisturbed, where their roots would not be mutilated by the spade, and where they would yearly increase in beauty and effectiveness. It is a mistake to plant bulbous-rooted plants in beds which have annually to be deeply dug. They not only do not appear at home in such places, but the yearly disturbance of the root prevents their attaining the amount of luxuriance necessary to give a true idea of their beauty. Spring-flowering bulbs of most kinds flourish best when growing in the shelter of a stronger vegetation, and should be grouped irregularly and naturally, not in rigid lines and formal circles, as is too often the case. No class of plants lends itself so ill to geometric gardening or appears so entirely misplaced when thus employed as that of flowering bulbs. The greater portion of them grow naturally amongst herbage of some kind, where the roots and bulbs are at all times well protected. The grower should, therefore, endeavour to imitate as far as may be these natural conditions. A charming plant for any garden is Anemone apennina. It should be allowed to remain and extend itself at will, and if the soil is well prepared for its reception, it will rapidly increase, producing, when its numerous mauve-coloured flowers are fully expanded, a most pleasing and cheerful effect.

There is also the scarlet Windflower (Anemone fulgens), with flowers of dazzling brilliancy, and Anemone japonica, already alluded to, a plant not nearly so much grown as it should be. Both the white and red varieties should be grown, and if planted together they will form a most pleasing picture at a time when most plants are quite past their best. Few flowering plants possess the power of resisting uninjured a continuance of inclement weather as does this beautiful Japanese Anemone. It flowers brightly and freely amidst the gloom and fogs of the autumn months, imparting colour and freshness at a time when such is sorely needed. There is also the pretty little Wood Anemone, which well deserves a place in the garden. A

very pretty effect is obtained by massing this plant with such subjects as Triteleia uniflora, the Dog's-tooth Violet, Scillas, and dwarf Daffodils. Little colonies of such plants as these, distinguished as they are for moderate growth, and not liable to encroach unduly one upon the other, will prove a source of permanent interest in a garden, and if planted in the immediate vicinity of trees or shrubs without any particular attempt at arrangement, allowing each plant to develop unrestrainedly and to mingle, if it so will, with its neighbour, the effect will be as pleasing as those natural combinations which one so much admires in our wild woodland scenery. Too little has hitherto been attempted in this way, but it is to be hoped that the time is coming when the permanent grouping of hardy plants will form an important part of the gardener's education. An extensive garden is by no means necessary for this purpose; there are plenty of beautiful plants suitable for gardens of the smallest dimensions which may be thus employed. The Lilies, for instance, may be grown in the smallest garden, and yet how seldom does one see the attempt made to render them justice. The handsome and fragrant Lilium auratum requires only to have its needs studied, and it will thrive in most places. Give it a proper rooting medium and a sheltered situation, and it will not fail to afford gratification. In cold, wet, ill-drained soils this Lily will not live for any time unless some special provision be made for its welfare. About 18 in. of the natural soil should be taken out, replacing it with some prepared compost. If good fibrous peat can be procured, this is the very best material that can be used; it remains sweet and free, and never becomes close and waterlogged, so that the bulbs when planted in it yearly increase in vigour. The only objection to its use is its expense, peat being in some localities rather difficult to procure. It is, however, far better to plant a few bulbs well, concentrating the labour and expense upon a few specimens, than to hurriedly commit to the ground a number of roots which could not well be accorded this necessary care. This remark will apply equally well to any other kind of hardy plant which it may be desired to establish. It too often happens that in the endeavour to accomplish a great deal nothing is thoroughly done, not one plant in the whole garden perhaps attaining sufficient luxuriance to give a true idea of its beauty. J. Cornhill.

Byfleet.

(To be continued.)

Improving a Lawn.—Until last autumn my garden had been much neglected—lawn 90 ft. by 40 ft., scarcely anything but weeds. I had it mown in spring and sowed 1 lb. of grass seed; have kept it cut regularly with the mower; it is now perfect. There are several Lilium auratums in the ground that have been there many years; I measured two to-day 52 in. each in height, 3 in. round base of stem, 19 blooms on one, 15 on the other.—Victor.

Wintering Hollyhocks.—If allowed to remain in the beds or borders where they have flowered, choice Hollyhocks often perish from damp or snow settling round their collars, or from its penetrating through the hollow cavity left by the too close removal of the flower-stems. It is a good plan at the approach of winter, say in October, to carefully lift all which it is desired to save, and lay them close together in a slanting direction, at an angle of about 45°, in a warm, mellow soil at the foot of a wall or hedge, where, in bad weather, shelter can easily be given them. But in wet, heavy soils it is the snow and damp that has the most destructive effect. Lifting them thus not only makes them safe, but it gives an opportunity to have the land that is to receive them thoroughly worked in winter, and then, when re-planted in March or April, if a little rotten turf is worked in with them, good spikes and large individual flowers may with tolerable certainty be expected. In the spring any strong plants that will bear it may be divided, as recommended, or if it is desired to increase any kind more largely, the plant may be potted and brought on gently in heat. Although the young side-shoots produced by old stocks will readily root in a gentle bottom-heat in spring, they may also be propagated in July, just before the plants come into flower. The side-shoots from the flower-spikes, or the smaller wer-spikes, if they can be spared, should be cut up into single joints, and dibbled in thickly in a prepared bed in a frame or pit, where they can be kept close and properly cared for by shading from bright sunshine, and sprinkling occasionally with water that has been warmed by standing in the sun. Thus treated, nearly every cutting will develop a latent bud from the joint of the base, and rapidly strike root, and make a good strong plant by the following spring; and, as a rule, young plants propagated at this season usually produce the best spikes. When cutting down the flowering stems of Hollyhocks after blooming, they should be left a good length, as they are exceedingly impatient of damp about their crowns; in spring their old stems may be removed altogether.—E. H.

Monkshoods (Aconitums).—These are stately hardy plants, well suited for wide borders, or for mixing among shrubs in large beds.

Variegated Monkshood (Aconitum variegatum).

They should, however, never be grown in vegetable gardens, as their roots, which are poisonous, have often been mistaken by inexperienced people for those of the Horseradish, and with serious results. The common Monkshood (Aconitum Napellus) will grow in any ordinary soil from 2 ft. to 4 ft. high, and, like the other kinds, is easily increased by division of the roots in autumn or spring. A. variegatum is, when well grown, a handsome plant, 4 ft. high, flowering late in summer. It flowers

Common Monkshood (Aconitum Napellus).

are sky blue variegated with white. The autumn Monkshood (A. autumnale) is a fine species, yielding from August to November spikes of large pale blue flowers tinged with white. A. chinense and A. japonicum are two of the best kinds, but they require warmer positions and soil than the foregoing; and A. paniculatum, also a handsome kind, grows best if a little peat is mixed with the soil.

Giant Musk.—We have employed Harrison's Musk successfully this season for decorative purposes. Early in the spring months, and even up to midsummer, we found it invaluable in pots for conservatory and house decoration. The most useful sized pot in which to grow it is a 5-in. one, using rich soil and good drainage. It requires a liberal supply of water, and occasional waterings with liquid manure are found to be of benefit to it. I have also used it largely for both beds and borders, and when planted in masses it is most satisfactory, being compact in habit and most profuse as regards bloom. Our beds of it were planted in April, and ever since the early part of May they have been a complete mass of flower. Heavy rains impair their beauty for a day or two, but they soon recover. This Musk flourishes best in a light, rich, moist soil, and if dry weather sets in occasional waterings will be necessary.—R., *Warwick.*

FRUIT.

Planting Apples.—Apples will thrive well on any good loamy soil on a bottom either naturally dry (that is, with no stagnant water in it) or artificially drained; on a bad sub-soil, whether hungry gravel or cold clay, the bottom of the hole should be made impervious to the roots before planting and the trees planted upon a slight mound. Where the soil is suitable, all the preparation required is to trench it up 2 ft. deep, and thoroughly break it up and intermix it. Manures, if applied at all, are better given in the shape of top-dressings when the trees come into bearing, so as to keep the roots near the surface. Where the sub-soil is unfavourable some expedient should be adopted to keep the roots out of it, either by spreading a barrowful of concrete over the bottom of the hole, 1 ft. 8 in. or 2 ft. from the surface, or paving the bottom with bricks or tiles, in order to give the roots a horizontal direction. All trenching should be done in September if possible, so as to give time for the ground to settle before planting. If at all loose the bottom of the hole should be well trodden just previously to the tree being planted. All fruit trees succeed best in a firm soil, and all planting should be completed by the end of November. Mulch with short litter or manure for 2 ft. or so round the bole of the tree as soon as the planting is finished. By early autumn-planting much time is gained, and the trees are in a good condition for heading down as soon as the sap begins to move in spring. If the planting be delayed till February or March, it would be better to leave the tops uncut till the following winter, especially if the roots have been mutilated in lifting them. Much care and judgment will be necessary in the selection of the trees, for it is preferable to plant half-a-dozen trees of a kind known to thrive well in the neighbourhood than to plant a number of sorts about the suitability of which for the soil little or nothing is known. This, of course, need not preclude any one from trying a new sort occasionally, and as it is important for the trees to be true to name, select them from some respectable nursery in preference to buying them in a market.

Gathering Pears.—During the months of September and October the bulk of the Pear crop should be taken from the trees, and should at once be placed in the fruit-room to ripen. Pears are improved in quality if ripened in the house under favourable conditions, to wit, darkness and a cool, dry, and pure atmosphere. Pears are very sensitive to surrounding odours, and if placed in a cellar with vegetables showing signs of decay their quality is injured. When the seed of the Pear has changed from a light straw colour to a dark brown the fruit may then be gathered, and will ripen without shrivelling or rot. Again, when on raising the Pear gently by hand it separates easily from its holding at the end of the stem, it may be gathered with confidence. To pluck Pears rapidly that are advanced toward ripening on the trees needs a practised eye and no small amount of experience; indeed, in many instances it will be found advisable to go over the same tree three different times in picking, and the additional labour will pay for the extra expense. Pears should always be taken from the tree by hand, and not shaken off, as is too often the case with careless cultivators. They should then be carefully placed in baskets and taken at once to the fruit-house or closet, to be laid away where the light can be excluded, with the same care, to prevent injury from bruising. There they may remain until ready for table use, with an occasional examination to remove decaying specimens. Compared with those ripened on the trees, their superior excellence will at once be evident.

Gooseberry Caterpillars.—I find that the best plan for getting rid of these is to allow young ducklings to go underneath the bushes.

They do not seem to molest the fruit, but they collect the whole of the caterpillars, and they jump up and pick off all within 14 in. or 15 in. from the ground. The following year hardly a caterpillar will be found upon the trees, as they seem to scratch out all the insects under the surface of the ground.—T. CHRISTY, *Sydenham*.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

September 20.—Sowing Cucumbers to be ready to plant on Dec. 20; potting up show and young autumn-struck variegated Pelargoniums, also Calceolarias, Snowdrops, Crocuses, Van Thol Tulips, and remainder of Roman Hyacinths; putting Caladiums on black flue to dry off, and putting pot Violets into a frame, Primulas into a heated pit, Tree Carnations into pits, and the earliest Cinerarias into a position near the glass; planting Roses for button-hole bouquets in a pit, the sorts being Isabella Sprunt, Cheshunt Hybrid, Devoniensis, Safrano, Niphetos, Madame Falcot, and Mdlle. Van Houtte; gathering Ribston Pippin Apples and Louise Bonne of Jersey Pears from espaliers; digging ground for Cabbage end Lettuce; clipping Yew hedges; hoeing among young Strawberry plants, Spinach, and Endive.

Sept. 21.—Potting Schizanthus, also a few Gem Nasturtiums for early spring work; putting Callas into pits, also under glass all bedding plant cuttings struck out-of-doors; planting Violets in frame; making up gaps in Cabbage bed; training and cleaning conservatory creepers; Peaches and Plums out-of-doors nearly over; hoeing among Winter Greens; picking over Rose garden; beginning to cover late French Beans out-of-doors at night.

Sept. 22.—Taking up all bedding plants intended to be saved; putting greenhouse plants under cover; planting Cabbages sown on Aug. 6; pricking out Cabbages for spring planting; staking Heliotropes; gathering Napoleon, Beurré d'Aremberg, Moorfowl Egg, and Bergamot Pears, also Brown Beurré and Gansel's Bergamot, and finished gathering Marie Louise Pears; digging border for more Spinach; earthing up Celery; keeping Cucumbers about 70°.

Sept. 23.—Sowing a border of Spinach, which will prove useful in spring; getting under cover all Tree Carnations showing flower, all Dr. Lindley and other Pelargoniums in flower, the white and yellow Chrysanthemums, and putting Bouvardias in heat for room decoration; taking up Centaureas, Carnations, Scrophularias, and Gazanias, and potting them; shifting Stocks into flowering pots; tying up Mignonette in pots; bunching up Basil and Marjoram; washing Orange trees; gathering Wine-sour Plums, also Crassane, Bergamot, Napoleon, Thompson's, Louise Bonne, Jalousie de Fontenay, and Louise Bonne of Jersey Pears; sorting seed Potatoes.

Sept. 24.—Shifting Humeas and Schizanthus into 8-in. pots; removing all Peach trees in pots from the orchard house and putting in Chrysanthemums; giving Mushroom bed a sprinkling of water and covering it with hay; preparing ground for early Peas; digging ground for Carrots to lay all winter in order to try to avoid grubs; thinning the latest Turnips.

Sept. 25.—Planting Lily of the Valley, Guernsey, and Belladonna Lilies, Schizostylis and Spiræas in sheltered positions, also Cucumbers to come on in January; making up conservatory baskets with Selaginella, Heliotropes, Centaurea gymnocarpa, Fuchsias, and Rollisson's Unique, scarlet, and Ivy-leaf Pelargoniums; potting Spiræa palmata; tying Anne Boleyn Pinks set with flower-buds and placing them under cover; finished gathering Reinette du Canada Apples; gathering the last of the Apricots; digging alleys between Asparagus beds.

Glasshouses.

Dipladenias.—To make the most of these, that is, to grow them in a way that will afford flowers for cutting over the longest period of the year, they must have no further rest than that which they get through the slower growth that is made during the winter. Allow them to get quite dry about this season of the year, and then at once cut them back to within a few joints of where the shoots have been shortened to the year preceding; then in the course of ten days, when the buds get prominent, but before they have broken into leaf, turn them out of the pots, shaking nearly all the soil away, and reduce the roots to something like the condition of large Dahlia roots when lifted in the autumn, a considerable portion of the small fibres being thus cut away. Then repot them in fibrous peat and sand. The pots used will not require in the first instance to be more than half the size of those which they have occupied during the summer whilst flowering, as towards February or March, when the roots have pretty well filled the soil, they can have another shift, which may be given without their receiving any check. They should be kept with their shoots close up to the roof and at the warmest end of the stove. Where there is only just sufficient warmth maintained to keep them alive during the winter, it would not be safe to pot them at all at this season.

Allamandas.—These may be had in flower almost all the year round by the use of several plants, encouraging some to make growth and flowers all through the latter months of the year, and drying one or two specimens off about this time. To effect this it is needful to let the soil get much drier than many plants would bear, allowing them to flag severely before any water is given, and then only administer enough to moisten the soil very slightly, for such persistent growers are they when in sufficient heat that if the soil is moistened to the extent that other plants need they scarcely can be induced to rest at all. From this time forward during the autumn months plants to be thus early put to rest must have no more water given to the roots than will prevent the leaves from shrivelling whilst in a green state.

Clerodendrons.—The climbing species of these are so manageable in a stove, that, where a sufficient number exists, they may be had in flower from March up to the middle of August. But this wide range in the time of their blooming, as a matter of course, necessitates their making growth at different periods; for, flowering as they do from the ripened wood, whatever cutting back is needed should be done immediately after blooming and before the plants start into growth. Those that flowered early will, in the course of a few weeks in most cases, have made as much growth as is necessary, when they may be prepared for resting by withholding water, much in the same way as in the case of Allamandas. The young shoots from the first having been all along kept trained close to the roof, the naturally hard character of the wood formed under such conditions is very conducive to free-flowering. Plants that bloomed later will be proportionately later in making growth, which they may be kept on making up to the end of the year. This late growth will flower just as freely as that made earlier, provided that whilst it is being formed the points of the shoots are kept close up to the glass.

Gardenias.—If all the stock of these show a disposition to set their flowers, a portion may be removed to cooler quarters, giving those that are wanted to bloom earliest more or less heat, according to the time at which they are required. Where a sufficient stock is at command they may be had in flower the whole year round by treating them so as to make growth at different times, and varying the management with different portions, so as to bring them on in succession.

Achimenes, Gloxinias, and Caladiums.—The season has now arrived when most of these will require drying off, a process which should be done gradually, keeping all in sufficient warmth, so as to admit of full development of the roots previous to the leaves dying quite off. This is best secured by withholding water by degrees, the plants during the interim being in a somewhat reduced temperature, but not lower than is necessary to induce a cessation of growth.

Guernsey Lily.—This very serviceable easily managed autumn-flowering plant is much less used than it deserves to be. Where a few dozens are grown and now placed in a brisk heat they will quickly throw up large heads of red flowers that have a handsome appearance on the plants which may be used when in bloom for the decoration of conservatories, and they are equally valuable in a cut state when mounted in the form of single flowers. They may be bought very cheaply in the market, and are excellent for windows, &c.

Roman Hyacinths.—In the whole range of bulbs for forcing there is nothing more useful than these for the production of flowers towards the end of the year; although they do not afford the diversity of colour furnished by the larger growing Hyacinths, yet it is much better to grow a portion of them than to attempt the forcing of the larger flowered kinds very early, as the Roman varieties come in with very little difficulty. They consist of white and blue, the blue being not quite so early as the white. They do not occupy much room—a 6-in. pot is sufficient for half-a-dozen bulbs—or they may be grown in pans a dozen or a score together, according to the size of the pans used. The soil, drainage, and general management do not differ from those employed in the case of ordinary Hyacinths.

Tying Azaleas.—The tying of these plants will, as a matter of course, be regulated by the purpose for which they are required. It is an unfortunate circumstance where plants have to be conveyed in bloom to an exhibition, even for a short distance, that it necessitates their shoots being secured to a much greater extent than for home decoration; for the latter purpose just a single stick to each of the principal branches is all that is needed, so as to keep them reasonably in shape without any formal training. If the tying is done now before the wood gets too hard, the leaves and ends of the shoots will assume a natural position. The whole of the plants ought to be gone over to see that they are free from their worst enemy, thrips, as if these are now destroyed along with their eggs no further inconvenience will be experienced from them during the winter, and there is a reasonable chance of the plants remaining free from them when growth again commences. After all the various remedies that have been tried, there is nothing so safe and certain of killing these insects without injuring the foliage as Tobacco water.

Paris Daisies.—The partiality which often exists for double flowers has caused many to be prejudiced against these useful decorative subjects, both yellow and white. Their single blooms being so much like those of the common Ox-eyed Daisy has hitherto been in the estimation of many much against them, but their elegant Fern-like foliage, which adapts them equally for cutting as for general decorative purposes in the form of pot specimens, with their easy cultivation and continuous blooming habit, render them amongst the most useful plants that can be cultivated for ordinary greenhouse and conservatory embellishment. Plants that have been grown with a view to their blooming in the winter, which they will do freely if placed in a little warmth, should not be allowed to remain out-of-doors too late. If they have had plenty of room in an open position, and if the leading shoots have been stopped in the early stages of their growth, they will now be strong and sturdy, requiring no support except it may be that of single sticks in the centre of each plant. Cuttings put in now in a little warmth and in other respects treated in the usual way will root quickly. They should be kept in small pots through the winter, and they will make pretty little plants in spring; or they may be grown on to a large size out-of-doors next summer.

Veronicas.—Where these are propagated in winter or spring, and then planted in the open ground with a view to lifting and transferring them to pots for autumn and winter flowering, it is not well to defer the taking them up too long, especially in a season like this when both earth and air are considerably lower in temperature than ordinary. All plants treated in this way should be turned out in soil sufficiently sandy and light to admit of their being taken up with no more mutilation of their roots than may be unavoidable. Although these Veronicas are naturally such free growers that they recover the loss of fibres much quicker than many plants, yet with those that come into flower early in autumn, such as V. Andersoni, injury to their roots more or less interferes with their blooming. They are subjects that require a good deal of water and will bear the soil to be thoroughly moistened as soon as potted in a way that would be fatal to more delicate-rooted plants; they should be set close under a north wall or similar position, so as to be out of reach of the sun for ten days or a fortnight after they are taken up; or if there happens to be room in a house or pit where they can be kept a little close, it will be still better.

Berry-bearing Solanums.—Plants of these also that have been similarly planted out should at once be taken up, using pots no larger than will admit their roots. If the soil is of a free light character, a good portion of it may be shook away and fresh material given them in the pots; these likewise should have the soil thoroughly moistened, or they will flag to an extent that will injure their leaves, a condition that must by all means be avoided, as it is to obtain plenty of healthy green foliage, which contrasts so well with their bright-coloured berries, that the planting-out system is advantageous. If pits or frames are at liberty that can be kept close and also shaded when it is sunny for two or three weeks, it will be the most suitable way of treating them. They may be placed tolerably close for the short time they are kept here, but not so much so as to injure the leaves. These plants, like everything else, are late, and in many places where there is a crop of berries on them grown to their full size, they are yet producing flowers. The points

containing these latter will be better pinched off. As soon as they are potted they should have a good washing with the syringe, so as to free them from any dirt that may have got upon them in taking up, and they may be damped overhead once or twice daily in bright weather until the roots have begun to act, after which it is advisable to discontinue anything calculated to promote top growth, as with many the object will be to get the berries of the earliest plants fully coloured with as little delay as possible. Cuttings made from the young, soft, still growing shoots of the earliest plants will strike readily treated in the usual way, kept moist in a moderate heat. This is not the usual season for the propagation of these plants, but cuttings struck now will be much in advance of and make better plants than those put in in spring at the ordinary time, or than those raised from seeds sown then.

Salvias.—There are many who treat these and other winter-flowering things of a like character on the planting-out system; in all cases they should be at once taken up and potted, treating them very similarly to the Solanums.

Flower Garden.

Carnations and Picotees.—These do not at present demand any more attention than to see they do not suffer from want of water. It easy to neglect plants out-of-doors during a period of dry weather, but if allowed to become too dry considerable injury is the result; the small roots that are forming at their callus die, and the plants are permanently injured. See that pots containing layers are fully exposed in an open position, but still they should be protected from the strong gales which are often experienced at this season from the south-west.

Hollyhocks.—Still put in any cuttings that can be obtained from the base of the plants, or eyes got from side growths from the main stem. Let all flowers with the seed-pods be removed, as they show decay if seed saving is not intended.

Pansies.—We are just now putting in cuttings of these, and it may be well to again remark that the thick, pithy flower-stems are useless for cuttings. The best are the slender growths that usually come up thickly from the base of the plants when the old stems have been pegged down or removed. These can be pulled out with plenty of small rootlets attached to them, and when carefully put into boxes in fine soil they speedily start into growth. A reddish-coloured aphis usually attacks them at this season, but it can be destroyed by dipping the cuttings in soapy water before they are inserted.

Polyanthuses.—Seed sown now will be up in about a fortnight, and in another fortnight the young plants may be pricked out in boxes or pans. Beds of seedlings or named varieties should be kept quite free from weeds by stirring the surface of the ground occasionally with a Dutch hoe. Plants in pots now well established must be well attended to with water, removing any decaying leaves and occasionally stirring the surface soil. Red spider frequently attacks the under sides of the leaves, and is not perceived until they begin to turn yellow. It can be destroyed as well as green fly by dipping the foliage in soapy water.

Pentstemons.—These are now very gay in herbaceous borders, and they will remain so for a long time. Few of our hardy flowering plants continue to brave the wet and cold so long as these do; it is, however, necessary to remove the seed pods as the flowers fade, as they seriously cripple the energies of the plants. The stems must also be supported with sticks as they require them. Cuttings may be put in now if a large stock is required, but we prefer to wait until October.

Marvel of Peru (Mirabilis jalapa).—I should like to call the attention of the readers of GARDENING ILLUSTRATED to the neglected but beautiful Marvel of Peru. It is so very easily cultivated, and with but little attention will grow to a beautiful bushy shrub; and at this time of the year it is covered with beautiful flowers of deep purple or white flowers, which open at night and emit beautiful perfume, and is well worth a place in every garden. The plant is raised from cuttings or from seed.—AMBROSE.

Fruit.

Vines.—Do not allow inside borders to want water, even though the Grapes are ripe, if there is any fear of their shrivelling from want of it; better sacrifice a few by damp than that this should happen. After watering, either cover the border with mats or dry straw, both for the sake of neatness and in order to prevent rapid evaporation. The earliest Vines, on which the Grapes are to ripen in April and May, should be pruned at once, the borders renovated, and the houses cleaned, or if they are to be painted the present is the best time to do it.

Melons.—Increased artificial heat both top and bottom will now be necessary to keep these in vigour, and the fruit must have the fullest exposure to light by tying aside any foliage that intercepts it. Though less water will now be necessary than earlier in the season, avoid dryness, which is a sure precursor of loss of foliage and consequent insipidity of fruit. Free ventilation, full exposure to light, and an equable bottom heat never fail to ensure fruit of high flavour. The blooms of late plants should be fertilised, and as the advanced season renders this crop somewhat uncertain, it will not do to wait for a number of flowers to be ready to fertilise at the same time; on the contrary, the first that appears should be set. Keep the shoots thin, and those producing fruit should be stopped at the first joint beyond the fruit. As soon as all are set encourage quick growth by closing the house very early. With sun-heat, the temperature may advantageously be raised to 90° for an hour or two.

Vegetables.

Where there are heated pits or spare spaces in Cucumber and Pine pits French Beans are easily produced, and a good quantity should be got in at once; for this purpose there is no better kind than Osborn's, though that fine variety Canadian Wonder forces at this early season tolerably well, but it requires more space than Osborn's. Seakale is yet in vigorous growth, but the first sharp frost will stop that, when a first batch of roots may be lifted for forcing. Due allowance, both as to produce and time required for forcing, must be made for immaturity of the crowns. In order to induce rest to the crowns of Asparagus that are intended for forcing earliest, cut away the stems to the ground line; these are still in such active growth that no attempt at forcing should be made for at least another month. Lettuces and Endive intended for winter use should have the protection of frames whenever frost seems imminent, for in order to prevent decay the first frost must be avoided.

Parsley and such other herbs as are in daily request throughout the winter should have immediate attention; the former, as a rule, winters safely on a dry south border, but a frame placed over it ensures its safety in all weathers. Basil, Tarragon, Balm, and Mint are all easily produced in any warm position in houses or pits, and if planted in pots or boxes they can be conveniently removed as required from one place to another. On fine days, and when the leaves are dry, tie up Endive and Lettuces to blanch, and all herbs not yet cut for drying should in like manner receive attention. Celery should also be earthed up under the same conditions as to weather, but previously remove all outside suckers, and prevent the soil from getting into the centres of the plants, either by tying or holding the stems closely together whilst the soil is being placed around them. Winter Spinach should be well thinned out, certainly to at least 1 ft. plant from plant. Canker is sometimes very injurious to this crop, and with the view of warding it off there is nothing better than keeping the surface soil loose, and taking the precaution to sow only on well drained ground. Continue to earth up Broccoli, Sprouts, Cabbages, &c., as occasion requires, and let no opportunity slip as regards killing weeds. Cauliflowers may require to have their leaves bent over their heads to evade frost, which may now occur at any time.

Messrs. Hurst & Son.—In consequence of 6, Leadenhall Street being required by the Corporation of London for City improvements, this firm has, after an occupation of nearly fifty years, removed the offices and seed shop to their extensive warehouses at 152 and 153, Houndsditch.

Notice.—We hear that many of our readers have, owing to the enormous demand, been unable to procure the number of GARDENING issued August 21, which contained a coloured plate of Roses, and also that many were charged by the newsvendors more for the number than the usual price, viz., one penny, which we need hardly say was entirely against our wishes and expectations. We would, however, remind our readers that they can still obtain the number without the plate either through the newsagents or direct from the office.

House and Window Gardening.

Berries for Room Decoration.—As soon as cut flowers become somewhat scarce in gardens, clusters of highly-coloured wild berries will be found in many cases to be a good substitute for them, and none are more useful at present than the fruit of the common Dogberry (Cornus sanguinea), to be found in many hedgerows in the southern counties, the berries of which are most effective when subjected to artificial light on the dinner table. I saw a few days ago a dinner table decorated in which these berries were employed, and with such success that I attempted to give a description of it. It consisted of a centre-piece only, and that was composed of a plateau on which stood a flower-pot of frosted glass, in which was placed a well-grown plant of Maiden-hair Fern (Adiantum cuneatum), and round the silver edge of the plateau was arranged a thick wreath of branchlets of the Dogberry; the effect of this wreath against the white of the damask cloth and frosted silver of the plateau was all that could be desired. The wreath was formed by just placing the little branchlets one partly over the other, so as to hide the stems; it was done in a few moments, and it kept fresh without any moisture all the evening. The berries of the Arbutus could doubtless be employed somewhat later in the season, in the way I have above described, with very good effect, and also others too numerous to enumerate. —H.

Hardy Plants Suitable for Outside Window Gardening.—

- Arabis albida
- Alpine Auriculas (cool position)
- Astilbe japonica
- Aubrietias, various
- Cheiranthus Marshalli, and others

GLASSHOUSES & FRAMES.

FEATHERY COCKSCOMBS (CELOSIAS) FOR WINTER.

Few plants are more striking in the dull days of autumn and winter than these lively-looking, graceful plants. Sow for a last batch of seed in August or early in September. Any light soil will do, covering but slightly, as the seeds are small. Place the seeds in pots or pans in a warm, close frame, and as soon as the plants are up, raise them near to the glass, as future success largely depends on a sturdy habit through the first stage of growth. Pot off as soon as the plants are large enough to handle, and plunge the pots in a bottom heat of 60° or so, still keeping the plants near the glass. Under such treatment the plants grow fast, and the pots will soon be full of roots. Shift into larger ones directly, until a 6-in. or 8-in. pot is reached. These sizes, unless immense plants 6 ft. high be required for lofty conservatories, will be sufficient. Properly managed and well fed with manure, a 6-in. pot will grow a Celosia 3 ft. high and almost as much through. Large plants, however, are not by any means the best or most useful for winter decoration.

Good, shapely pyramids, about 2 ft. high, in 6-in. pots, are much more useful, as they will stand on a shelf in any out-of-the way part of the stove, and yield quantities of blossom for

cutting, and also lighten up, by their many spikes of beauty, foliage or other plants. After their final shift the Celosias should gradually be removed from a tropical to a more temperate climate ; a warm, light greenhouse is about the best situation for them. This final shift should be into rich soil, composed of tufty loam and leaf-mould, with a free admixture of sand. For summer work the Celosia may have a much richer soil—half of loam and half of rich manure. But less forcing food is better and safer for those that have to pass through the winter. The chief enemies of the Celosias are thrips and red spider ; both dislike a moist regimen, and the Celosias delight in frequent syringings overhead. Hence, if the plants be shaded, the pests do not get much hold. Should they, however, do so, smoke twice at least in succession with Tobacco paper, and, in fact, continue smoking until the pests are dead. Nothing is more fatal to the health and beauty of Celosias than red spider or thrips ; these mar the beauty of both leaves and flowers and arrest growth. The spider especially delights in these plants ; and this is one reason why all their early growth should be made in bottom-heat, that from fermenting manure being by far the best.

The pyramidal flower-spiked Celosias have almost driven the old crested sorts out of cultivation, and deservedly so. The old Cockscombs were grand things in their way, but required a good deal of skill and care to grow them well, and they refused to group effectively with any other plants. There is a large crimson comb, beautiful enough in its way, but it was not and never could be made anything more than a comb. Now these new Celosias or Cockscombs group well with all kinds of plants, and are among the most useful of any for cutting for vases or bouquets. Groups of Celosias are very showy by themselves, and have a still richer effect mixed with such strikingly beautiful foliage plants as Amarantus Henderi, A. salicifolius, and A. tricolor.

There are a great many varieties of these feathered Celosias, ranging through the different shades of colours from lilac to crimson, and yellow to orange. Almost each grower has his own specially good strain, distinguished either by its superiority of vivid colouring, size, or profusion of bloom. Among the finer named sorts are the following : C. pyramidalis aurea, fine golden ; C. p. ignea, rich crimson ; C. p. aurantiaca, fine orange ; C. P. plumosa aurantiaca, in different varieties of colour, such as C. splendida and C. versicolor violacea, is a very fine strain, producing feathery-looking flowers of great richness and beauty. T.

Tropæolums for Winter Blooming.—Any of the free-blooming, climbing varieties of Tropæolum are very serviceable for the production of flowers through the winter, and for this purpose they are often trained up pillars or rafters ; so managed they bloom profusely, and produce a cheerful effect, but they are not so useful as when trained to a few sticks inserted in the pot, as in this way they can be moved about to whatever place is most conducive to their blooming. If they can be accommodated with a temperature of 50° at night, with plenty of light in the day, they will keep on flowering for months. The length of stalk possessed by each bloom, and their enduring capabilities when cut in water or wet sand, make them very useful for small vase decoration. Amateurs with limited glass accommodation for growing winter flowers will find that by employing free-growing, continuous-blooming plants such as the above they can have a much more plentiful supply than by attempting the growth of subjects that are rarer and more difficult to cultivate.

Genetyllis.—These beautiful greenhouse plants, sometimes known by the name of Hedaroma, are by no means easy to cultivate, and can only be recommended to those who can pay attention to their plants, and who have learnt how to pot a plant and how and when to water a plant, for if these plants once get dry they are seriously injured, and if they get waterlogged death is almost certain. In nurseries they are grown with ordinary care, and flower from midsummer to late in autumn. The principal kinds are G. Hookeriana, which flowers earliest in the season, G. tulipifera, which succeeds it, and G. fuchsioides, which blooms in autumn and winter. The best soil for these plants is one-half fibrous peat, one-half fibrous loam, and abundance of silver sand. They require to be potted firmly, like an Azalea, and when they require larger pots the next size to those they are in should be used. A cool, airy house is the best place for them. All the kinds of Genetyllis are easily increased by means of cuttings, made of the side shoots, put in in April and May. The pots for their reception must be prepared, so as to allow ½ in. from the rim for bell-glasses to stand on. The soil should consist of half peat, and the other half clean yellow loam and silver sand sifted fine and pressed into the pots, which must be well drained, rather firmly. Make the cuttings as shown in the accompanying illustration, put them in firmly, and give a good watering. After the lapse of an hour or so the glasses may be put on, and the pots placed on a gentle bottom-heat (a tan bed is best). In order to obviate an excess of moisture the glasses should be taken off and wiped every other morning, an operation which must receive particular attention, or the leaves will fall off. As soon as the cuttings begin to grow tilt the glasses daily for a few hours, and by degrees they may be left off altogether. The young plants thus raised will be ready for potting off and placing in a

Cutting of Genetyllis.

shady, cold frame in August, keeping them close and shaded from sunlight.—H.

ANSWERS TO QUERIES.

2891.—**Pansies in Pots.**—Last August I had some rooted cuttings ; I put them into round seed-pans, ten in each, in good mould got from a nursery. They were kept in an unheated greenhouse, given plenty of air and not much water ; in February I potted them into 7-in. pots, good drainage and a handful of rotten manure over same, plenty of water when they began to grow freely, and Florvita twice a week when the flower-buds showed, and from the first week in April till I had to put the plants out of the house to make room for others, three weeks ago, I had lovely flowers. When potting put a stake in, as they grow very tall and require to be tied up, and it only injures the roots putting the stake in afterwards.—E. G. F.

2880.—**Propagating Azaleas.**—Ghent Azaleas are propagated by means of cuttings and seed. Nurserymen keep old stools of the best kinds, which throw up from the root-stock a number of straight, strong shoots, which early in the year are bent down, cut partly through with a sharp knife, fastening that portion into the ground with a stout peg. By the end of the season roots are emitted and the young plants may be taken off. Seed should be sown in March in well-drained pans of sandy peat, covering the seed very thinly, and placing the pan in a cold frame, covering it with a pane of glass until the seedlings appear above ground. As soon as they are large enough to handle, prick them out into sandy peat, and keep them in the frame until well established, when they should be gradually inured to full exposure. The following year, having wintered them in a cold frame, they should be planted out in a bed of prepared soil about 9 in. apart, where, if carefully tended, they will make a good strong growth.—J. C.

2882.—**Soil and Treatment of Orchids.**—Cypripedium insigne and Bletia hyacinthina require a compost of fibrous peat, taking the lumpy portion only, mixing with it a little chopped Sphagnum and crushed charcoal. The Odontoglossum and Dendrobium nobile are better for about a third Sphagnum. The Bletia is said to be hardy, although we do not think that it has been thoroughly proved in this country. It would probably succeed in a cold house, but might be grown in company with the other above-mentioned species, which demand a minimum temperature of from 45° to 50° by night and 55° by day in the winter. During the summer season they should be placed in a light position in a close moist house, shading from bright sunshine. Whilst the plants are in a growing state keep the soil moist, but as soon as growth is completed diminish the supplies of water, and give air rather freely. This treatment will have the effect of maturing the bulbs, thus enabling them to produce bloom at the proper time. The Cypripedium may, if so desired, be removed to a warm room when throwing up flower ; it thrives very well in such a situation. In potting, fill the pots quite half full of drainage, and press the soil in firmly.—J. C. B.

2845.—**Mushrooms in Boxes.**—To grow Mushrooms anywhere, the manure must not be rotten, but taken fresh from the stables and fermented, permitting some of the moisture and rankness to escape by turning it over occasionally for a period of about three weeks. If the manure was used quite fresh, it would become fiery hot, and heat itself so dry that the spawn would not run in it, except round the edges. The chief difficulty with inexperienced Mushroom growers is in the preparation of the manure. It is either used so hot as to destroy the spawn, or else it has been over-heated, and the nature and strength taken out of it, so that it will not generate sufficient warmth to propagate the spawn and enable the Mushrooms to grow. I have often grown good Mushrooms without fermenting the manure by mixing one barrowful of fresh loam or soil to every four or five barrowfuls of manure just as it came from the stable, with the longest littery part only removed. The soil steadied the temperature, and consequently prolonged the heating power as well as absorbed all ammoniacal gases. Such beds, when well put together, are generally lasting and prolific. The beds must be built up firmly in layers, putting a portion in the boxes, pressing it down firm, and then add more, making that also firm, and so on, till the boxes are full. Place a stick in each box to indicate the temperature. As soon as it falls below 90°, spawn by inserting pieces about the size of a bantam's egg, 6 in. or 8 in. apart, just under the surface. When the spawn is working freely, put 2 in. of fresh sweet soil on the top, and beat it down firm with the back of the spade. The boxes should be kept in a temperature of 55°. A dark place will be best, as there will be less evaporation from the surface. No water will be required till the Mushrooms appear, unless it may be a light dewing over with the syringe.—E. H.

2883.—**Trees for Front Garden.**—A little more information as to the position of house, whether town or country, would have been useful, also as to size of forecourt, but the following list may be useful : Conifers—Cedrus Libani, Cupressus Lawsoniana and varieties, Thuja Vervæneana, Cryptomeria elegans, Thujopsis borealis, T. dolobrata, Picea Pinsapo. Weeping trees—Birch (Fern-leaved), Sophora japonica, Acacia inermis, Cratægus Pyracantha (grafted on 4-ft. stems). Japanese Privet makes a handsome little tree grafted on 3-ft. stems. The following are useful trees if there is sufficient space : The Plane, Lime, Thorn, Laburnum, Evergreen Oak, Magnolia tripetala, Mountain Ash, Hollies (many kinds), if the soil and situation suits, and the same may be said of the Rhododendron, but it is not much use planting either of these last named in a smoky confined atmosphere. It is difficult to advise without knowing something more of the locality than the question supplies.—E. H.

2879.—**Striking Rose Cuttings.**—Something depends upon when and where the cuttings are put in. If struck in a heated frame in spring or summer, then the chief requisites are a regular even state of moisture, with a close atmosphere and shade enough to keep the leaves from flagging. I have said a close atmosphere is essential, yet it must be changed as often as is necessary to prevent damping off. If the cuttings are planted in a cold frame in au-

tumn, or in the open air, much less trouble will be incurred, although the same rules apply ; and the nearer the conditions are secured the better the cuttings will root.—E. H.

2893.—**Saving Cabbage Seed.**—Seeds saved in a hap-hazard way are not often worth the trouble, and if the Cabbage is only running to seed now it will be too late to ripen. If "C. F." decides upon leaving it for seed and taking his chance about it ripening, he should thin out the clusters of pods where thick to give the remainder a better opportunity of ripening. When ripe it must be gathered and rubbed out.—E. H.

2840.—**Unproductive Potatoes.**—Let your Champion Potatoes remain by all means as long as they have a green leaf to show, as your only hope of getting any produce is to let them have all the time to produce tubers that the season will admit. Your experience with the Champion is that of hundreds of others who have been induced to plant this coarse and vastly overrated Potato. It is not disease-resisting even, as so often declared, as we have already seen it badly diseased in the tubers, whilst its competitor in this important characteristic, Magnum Bonum, is quite free and healthy, and, still further, is now turning out a splendid crop of tubers of quite three bushels to the rod. We strongly advise you next year to get rid of your Champions and replace them with the Magnum Bonum, giving the rows quite 3-ft. intervals. Don't be afraid of plenty of space ; the result always is a better crop and handsomer samples than can be got when the plants are so close together. The present season has induced an inordinate haulm growth, and so far in the Champion few or no tubers.

2841.—**Houseleeks.**—Nearly all the dwarf or cluster kinds of Sempervivums will thrive on a house roof, and one of the prettiest when in good clumps is the Cobweb Houseleek (Sempervivum arachnoideum). You will also find californicum and montanum, both kinds much employed in carpet bedding useful for your purpose. A pretty free-flowering kind is Sempervivum Boissieri, and the plant forms a large handsome rosette of leaves. The common Houseleek is Sempervivum tectorum, and formerly enjoyed the reputation of being capable of removing warts by rubbing these fleshy protuberances with the bruised leaves.—A. D.

2899.—**Flowers for Window.**—It is impossible to keep up a supply of flowering plants throughout the winter without the aid of a glass structure, but a fair amount of bloom may be had in early spring. Chinese Primulas should be sown in May and grown along in the frame until the latter end of October. Cyclamen bulbs may be potted in August, and young plants of Lobelia grown along during the summer, picking off the blooms, will flower beautifully in spring. Fuchsia Rose of Castile, Lady Heytesbury, and Mrs. Marshall are early-blooming kinds. Mignonette may be sown now, and will flower early in the year. The best use to which the cold frame could be put would be for sheltering hardy annuals in pots, such as Godetia Lady Albemarle, Nemophila, Saponaria, Myosotis dissitiflora, Silene compacta, &c. Well drain some 4½-in. pots and fill them to within ½ in. of the rim with fine soil. Sow thinly and cover lightly. Shade and keep moist until the plants are well up, and then expose them night and day until November, when heavy rains must be warded off, and the sash should be put on in frosty weather. With the exception of keeping the soil moist, no other care will be needed, so that by early spring they will be finely in bloom. I should, however, mention that not more than three plants are to be left in a pot. Primroses and Polyanthuses may also be potted ; and thus cared for, they will make the window gay and cheerful at a time when the garden in the open air is comparatively bare of colour. Hyacinths, Snowdrops, Tulips, Crocuses, &c., may be potted in November and wintered and grown in the frame ; and last, not least, the Christmas Rose may be potted and thus sheltered, as it comes much finer thus treated.—J. C. B.

2920.—**Verbenas from Seed.**—Sow the seed as early in spring as convenient in well drained pans or pots of light sandy soil composed of equal parts of leaf-mould, good loam, and silver sand. Fill to within 1 in. of the rim and water freely. Then cover with ½ in. of dry soil, and press level with the bottom of a small flower-pot. Scatter the seeds thinly on this, press gently into the soil, and cover very lightly with finely sifted soil. Place the pan in a warm frame quite level, with a piece of glass on the top, and keep moist. When the seedlings are fit to handle, pot separately into 3-in. pots, replace in heat, and keep close and shaded till established. If for bedding, they can be planted out when all frost is over, having been previously hardened in a cold frame, or under hand-lights. They will thrive under the same treatment as other bedding plants, but will require pinning down with zinc or wooden layering pins. A sandy soil and sunny situation suit best.—S. G. B.

2969.—**Plants Under Trees.**—Hardy annuals, such as Collinsia, Nemophila, Bartonia, Saponaria, and Leptosiphon, may be sown now to bloom early in spring, and may also be sown again in March for a summer display, as well as Godetia, scarlet Flax, dwarf Tropæolums (in the sunniest place), and Convolvulus minor. Silene pendula and Myosotis dissitiflora may also be sown now. In the shadiest situations we would plant Snowdrops, Daffodils, Primroses, and Polyanthuses, which succeed best when partially screened from the sun. Of the two latter seed may be sown in April in light soil, and the seedlings may be transplanted when large enough to their permanent quarters. The border alluded to should be deeply dug this autumn, forking in a little manure. In the spring any of the annuals above mentioned may be sown, from March till June, at intervals of a fortnight, thus giving a succession of bloom. We would also strongly recommend the bedding Violas and Pansies, which flower from early spring till late in autumn. For the back row we would have Honesty, Wallflowers, Sweet Williams, and Columbines, the seed of which should be sown in March in free soil, and the young plants set out where they are to remain when large enough to handle. Put one plant in a place, and attend to them during the summer, and they will flower beautifully the following spring. There are many beautiful hardy plants which may be planted either in the autumn or in early spring, such as the lovely Japan Anemone, both white and red varieties, Achillea ptarmica fl.-pl., Campanula carpatica and turbinata, Aubrietia purpurea, Alyssum saxatile, Spiræa palmata and filipendula fl.-pl., Anemone fulgens and apennina, Polemonium cœruleum, Solomon's Seal, Lily of the Valley, Pæonies of sorts, the White Lily, the Tiger and Orange Lilies, Daisies, Saxifraga granulata fl.-pl., Gentiana acaulis, Lithospermum prostratum, Iberis corræfolia, and Arabis albida. All these are easy of culture and effective. Here and there a Clematis might be planted to be trained up to a stake, and climbing Tropæolums, Canary Creeper, and Sweet Peas may be treated in the same manner.—J. C.

2967.—**Growing Bulbs Indoors.**—Tulips, Narcissi of many kinds, Scilla sibirica, Crocuses, Snowdrops, Triteleia uniflora, Jonquils, and the Grape Hyacinth may all be grown successfully in the dwelling. The bulbs should be procured at once and potted in a compost of good free soil, consisting, if possible, of two-thirds loam and one-third leaf-mould, with the addition of a little sand. Bury the bulbs about 1 in. under the soil, pot firmly, plunging the pots up to the rims and covering with 3 in. of ashes. At the turn of the year remove them to the dwelling, place in a light position, watering carefully until the plants are well in growth, when more copious supplies will be needed. Good single kinds of Hyacinths consist of L'Ami du Cœur, Eldorado, tubiflora, Orondates, Uncle Tom, and Fleur d'Or. Doubles—Alida Catherina, Princess Royal, Blanchard, Albion, Rembrandt, and Heroine.—J. C.

Tulip-flowered Genetyllis (G. tulipifera).

2971.—**Wintering Coleuses.**—As you have no warm greenhouse, we would advise you to keep the Coleus in a constantly heated apartment from the latter end of September. Keep the soil on the side of dryness, and water with warm water. The foliage may be occasionally sponged, but all moisture should dry off by the evening, and in severe frosty weather the plants should at night be placed in the warmest corner

of the room and be covered up. In this manner the Coleus may be brought through the winter. —B.

2980.—**Gloxinias for Autumn Blooming.**—Gloxinias require no artificial warmth at this time of the year; it is in spring, when making their growth, that they need a warm house. They will soon begin to die off, when water must be gradually withheld until the foliage has turned yellow, when the bulbs should be turned out of the pots, packed in Cocoa-nut fibre or sand, and kept in a warm place throughout the winter. In April pot them in the same-sized pots in sandy peat, and place them in the warmest place at command. Shift into larger pots about the beginning of June. Shade from hot sun, and water carefully.—C. B.

2994.—**Preparing Ground for Potatoes.**—Where it is purposed to plant a piece of ground with early Potatoes we would not advise the putting of any crop upon it now; indeed, it is not possible to get from it any crop that could be profitably removed in time. The best thing to do will be to work in some long straw manure and throw it up into 2½-ft. ridges for the winter; then in the early spring put a further dressing of long fresh stable manure into the furrows, fork this well in, and plant the tubers on the top of it. The benefit derived from this course is that the long manure changing its texture but little during the summer acts as drainage, keeps the tubers free from moisture, and at the same time induces free and healthy growth. We have found the most beneficial results to follow from this mode of culture during the past season, and the tubers have lifted very fine, sound, and clean. When the tubers are laid in the furrows the pulverised soil should be forked over them from the ridges on either side, and later on the forking, if possible, done with the fork, as the best implement of culture. As to sorts, there are none better for first early work than the Ashleaf Kidney, if a good stock, or Fenn's Early Market, a capital round white kind, or Beauty of Hebron, the best of all the American Rose kinds, a heavy cropper and excellent quality. Of course, what kinds are to be preferred may be very much a matter of taste, but for general frame purposes there are few kinds that answer better than the old Ashleaf Kidney. —A. D.

2988.—**Fuchsia splendens.**—Whether or not Fuchsias should be dried off at the root for the winter must depend upon the temperature of the house in which they stand. If a cold house where the frost is simply excluded the plants are best dried off if the plants are large, but if small, then let them be kept growing on. As a rule, they are dried off, because then the plants may stand under the stage for the winter, and thus make room for other things. Your Fuchsia splendens evidently is not happy in the soil in which it is, or else it has been kept too dry at the root. If the roots are pot-bound, that is the most probable reason of its failure. All Fuchsias should do well in an ordinary greenhouse at this time of the year, as most of them prefer a cool temperature. It will be time enough to begin drying off Fuchsias when the winter is really here.—A. D.

2722.—**Rusty Water.**—With reference to the incorrectness of the part of my answer to this query regarding the use of lead pipes, I beg leave to say, that in a short answer to a query on a matter where injury to health is concerned, and covering a number of varying cases, it is best to err on the safe side, and leave out the exceptions when those are few and complex. I have always understood that the principal danger in the use of lead pipes and cisterns was not the formation of soluble oxide of lead through the doubly oxygenated air which all waters in which a fish can live must contain, but the formation of lead carbonate or white lead, from combination of the metal with the free carbonic acid which most waters contain, especially those hard waters which are derived from chalk or limestone. The introduction of this salt into the human system in continued minute doses is the cause of the disease to which house painters are subject, known as painters' colic. The formation of a coating of a salt of lead which is insoluble in the acid which forms it only takes place when the acid is allowed to remain still while the coating is being formed. In etching on type metal plates it is found that keeping the acid in motion prevents the coating of the metal, and enables the plates to be bitten to the required depth. I found in making experiments that disturbing the acid every five minutes or so, and pouring it off, and substituting fresh about every twenty minutes, prevented the coating of the metal, the insoluble salt appearing in the form of grains like very fine sand. The following extract from "Elementary Chemistry," by the Rev. H. Martyn Hart, M.A., gives the dangers of using lead pipes in as few words as possible: "Lead, on account of its pliability, is much used for water-pipes and cisterns, but it should never be used for storing rain-water, for this is pure water containing air, and in such water the oxide of lead is soluble, rendering the liquid poisonous. Well-waters, containing nitrates and chlorides, act on lead, forming soluble salts, therefore they should not be brought into contact with it; but hard waters have little or no action on the metal, for a thin deposit of sulphate or carbonate is formed on its surface, preserving it from further attack. However, water charged with carbonic acid gas is capable of dissolving the lead carbonate to a dangerous extent. Water should never be kept in a lead cistern; for if it contain any carbonic acid gas, a lead carbonate would be formed, which renders the water poisonous." This extract it will be seen vetoes the use of lead cisterns and pipes for nearly all waters, except those which owe their hardness to sulphate of lime or magnesia, as waters from chalk or limestone owe their hardness to holding carbonate of lime in solution, which they could not do unless they contained free carbonic acid gas in solution also. My own experience of the injurious effects of lead pipes is limited to water pumped from the chalk. If coating the pipes inside with sulphate of lead will prevent carbonic acid from acting on them, it is a thing which cannot be too widely known.—The etching of lead cisterns by leaves mentioned by "J. B." would take place, not by the action of the acetic acid, but by that of the carbonic acid gas which escapes from all vegetable matters in the process of decay. As water is capable of retaining a considerable quantity of this gas in solution, and the more of it the more rapid will be the corrosion of the lead, it will be seen how dangerous it is to allow dead leaves and the dust of vegetable decay to get into lead cisterns containing drinking water.—J. D.

2844.—**Creeping Jenny.**—Although I have grown this plant for years under various atmospheric conditions, it is quite new to me to hear of it being affected with a white blight. Whether in London, or in a smoky Lancashire town, or at the seaside, where I am located at present—whether in the open or under the shade of trees, my Creeping Jennies never exhibit any sign of blight, but thrive most luxuriantly. With heavy soil I use a good proportion of well-rotted stable manure. Here in West Lancashire, where sand is over plentiful, I make a liberal use of cow manure, and, with plenty of water and a dose of liquid manure once or twice a week, my plants are dense masses of healthy greenery. "Marguerite" had better discard her present stock of Jennies, and obtain a fresh supply, planting them in moderately open and rich soil.—SAXON DEYNE.

2979.—**Moles in Gardens.**—I had a mole in my garden, and I procured a spring trap from the ironmonger's—price 7d. I got a friend who had had some experience in catching these animals to set it for me, and in two or three days we had him. It is said that the green leaves of the common Elder placed in their subterranean paths smell so offensive to them that they will not come near it. Or they may be poisoned by placing in their paths worms which have been left for some time in a small quantity of carbonate of barytes.—G. ROBJENT.

2835.—**Sowing Flower Seeds.**—It is too late to sow the seeds named by "J. T. M." True, the plants might be raised, but the difficulty would be to keep them through the winter, and even if that were successfully accomplished, there would be little or no advantage. Carnations sown in the open next May would bloom quite as soon as if sown now. Lobelias will be quite as useful sown next March. I have some in splendid bloom now sown last March. Pelargonium seed should be sown in the beginning of the year, but if you have only a cool frame March will be quite early enough. At the same time I think you will succeed best with cuttings rather than raising Pelargoniums from seed. Cockscombs are annuals; about March is the time for sowing seed. To grow them well requires a greenhouse. As to soil for seed sowing, it should be moderately rich, light, strong, and porous. Fibrous loam from rotted turves, decomposed manure from an old Melon or Cucumber bed, and silver sand will make a nice useful compost in which the tender rootlets will luxuriate. Grass turves cut from an old meadow now and stacked in a heap with the Grass side downwards, although best at two years old, will come in useful next year if decomposition is hastened by placing a thin layer of muriate of lime (see answer to query 2834) between the turves.—SAXON DEYNE.

2969.—**Plants under Trees.**—I have had a variety of plants under the shade of trees this year with the following results: Creeping Jennies, Pansies, and Antirrhinums have done well; Phlox Drummondi and shrubby Calceolarias fairly well; Stocks, Clarkias, Indian Pinks, Mignonette, and Geraniums very, very poor.—SAXON DEYNE.

2929.—**Tomatoes.**—Sow the seeds in a pot in the last week in March, placing the pot in a warm kitchen; when the seeds germinate place them in a window in a warm room, removing them at night; thin out and transplant into separate pots, placing the same out-of-doors in a warm place; take indoors every evening early until large enough to be permanently planted.—H. S. YOUNG.

2841.—**Houseleeks on Roofs.**—Sempervivum triste is one of the best, and succeeds well with me in the chinks of the sloping top of an old wall. The peculiar dark foliage contrasts well with that of the common Houseleek. S. arachnoideum forms pretty tufts of green and white. There are several other hardy sorts which do well on old walls, but it is not stated of what material the roof is composed.—W. D.

2966.—**Ivy for Fernery.**—There is no better kind than the small-leaved variegated variety. It does not grow very strong, and always remains charmingly fresh and bright, especially when in a shady situation.

2993.—**Blooms of Begonias Falling.**—The plant must have received some injury, probably at the root, caused by an overdose of water. The Begonia soon suffers when over-watered.—J. C. B.

Although the following questions are answered by the Editor, he will be obliged to any of our readers who may think well to answer them according to their experience.

3054.—**Pruning Plum Stocks.**—I grafted some Victoria Plums this last spring; the shoots are now 3 ft. to 5 ft. long. Should they be pruned? or how treated? —W. G. K. [Let them remain till January; then prune them back to three or four eyes.]

3055.—**Placing Vines Out-of-doors.**—I have a small greenhouse and Vinery combined. The flowers are all out of it at present, and the roof covered with the Vines. The roots are outside, and the stems enter by a sash. I should like to take the heads out through the window now and supply their place with flowers which have been in a cold house since spring. Is it too early? the leaves are only beginning to get yellow.—BERTHA. [As the weather is so unusually fine you may turn them out at once with every chance of the wood ripening. Secure them to strong stakes.]

3056.—**Plants under Trees.**—There is a corner in my garden under a large Sycamore tree where nothing will grow. I have tried Periwinkle and common Ferns, but without success. The soil is sandy. What would be the best plan to adopt?—E. F. [Plant Ivy in a circle 9 ft. or 12 ft. or more from the base of the tree, and train it towards the tree. Dig out holes in which to plant, and put a little manure in the bottom of them.]

3057.—**Improving Soil.**—Having within the last two years made an extension of my lawn from an old pasture field, I find the flower borders in it have impoverished the flowers and bulbs I planted; the soil is stiffish clay. How shall I go to work to render this soil fine and rich?—E. B. D. [Take up the plants and give a good dressing of rotten manure and leaf-mould and road sand. Dig the ground deeply, and well incorporate the manure with it as the work proceeds; then replant.]

3058.—**Dielytra spectabilis.**—I have a large plant of Dielytra spectabilis which I wish to move to another position. It is more than 9 ft. round and tall in proportion. I shall be obliged to know the proper season for moving it safely.—D. S. [Now.]

3059.—**Propagating Geraniums.**—By what method can I procure slips of Geraniums? and how shall I propagate them? I have only a small space available in my greenhouse, which is without any heating apparatus.—ERNEST LLEWELLYN. [Take shoots of the firmest wood 6 in. long, cut close under a joint, remove the bottom leaves, and insert firmly in pots half-filled with broken crocks and very sandy soil. Place out-of-doors in shade for a week; then remove to greenhouse.]

3060.—**Carnations.**—What are those Carnations called which have the flakes or bizarres, as the case may be, on a red, purple, or crimson ground instead of white? —FLOS. [Red bizarres, purple bizarres, or crimson bizarres.]

3061.—**Stag's-horn Fern.**—I have a Stag's-horn Fern which has done well in my drawing-room all the summer; will it live and thrive in the same room in winter? Aspect south-west.—CLARE. [Yes, if the room is warm, and there is not much gas burnt in it.]

3062.—**Glass for Frames.**—*Light and Shade.*—Rolled cathedral glass will do for a frame in which to winter common plants like Geraniums, &c. It is, however, no better than ordinary window glass.

3063.—**Ripening Vines.**—Please say whether Vines in a cool Vinery will best ripen with the house kept closed or thrown open.—CONSTANT READER. [Thrown open.]

3064.—**Treatment of Strawberries.**—*Novice.*—Please refer to recent articles which have appeared in GARDENING.

3065.—**Rhubarb Running to Seed.**—*Novice.*—Put plenty of manure into the soil, and keep the seed stalks cut off as soon as they appear. Lifting is not advisable.

3066.—**Diseased Bark on Fruit Trees.**—*J. W. C.*—It is no disease. The branch dies first and the little red spots follow; you can find the same kind of thing on any old Pea stick. You must look elsewhere for the cause of branches dying.

3067.—**Abronia umbellata.**—*Indoctus.*—A cold frame will be sufficient protection for plants of this, unless the winter is very severe. If sown in September, grow out of doors until frosts occur; then move to the frame, and give no more coddling than is really necessary. This Abronia is, however, best sown in spring.

3068.—**Red Spider on Vines.**—*C. B.*—Red spider may be checked by sulphuring the hot-water pipes when they are highly heated, and the temperature of the house has been raised to 80°. Mix the sulphur to the consistency of paint, close all the ventilators, and apply it at night with a whitewasher's brush. Wash it off the pipes the following morning, and ventilate before the sun strikes the roof. Repeat the sulphuring once or twice at intervals of two or three days. Examine the borders and see that they have not been kept too dry. One of the most fertile causes of red spider is dryness at the roots, and the best preventive is giving them abundance of liquid manure throughout the growing stage. It should, however, be borne in mind that a heavy drenching may do serious mischief to the Grapes now about ripe. Syringe thoroughly as the Grapes are cut, and properly cleanse the house and Vines at pruning time by carefully scrubbing the rods, trellis, and woodwork with strong soap and water. Wash the walls with quicklime, and remove every particle of loose mulching and inert soil from the surface of the internal borders. This done, make a solution of Gishurst Compound, 8 oz. to a gallon of soft water, and apply it to the rods and spurs with a painter's brush. Watch the Vines closely in the spring, and should spider reappear sponge the young leaves with soapy water before it has time to spread. Any plants that may be in the house should be placed on the floor or removed outside while the sulphur is being used.

3069.—**Cauliflowers Turning Soft.**—*Souton.*—The land wants well manuring. Leaf-mould is of little use for Cauliflowers. As there are many kinds brought into Covent Garden, we do not know to which you refer, but Early London and Walcheren are the kinds chiefly grown for market.

3070.—**Propagating Epacris.**—*Vicar.*—Half fill some 6-in. pots with broken crocks, put a little Cocoa-nut fibre or Moss over them, fill up firmly with sifted peat and plenty of sand, and put ¼ in. of fine silver sand on the surface. Well water with warm water and let the pots drain for an hour; then insert ½ in. apart cuttings of the young tops about 1 in. in length, removing the bottom leaves with a pair of scissors. Water to settle the soil, and place in a close frame or greenhouse under a bell-glass, and shade from sun. Remove bell-glass for an hour each day, and keep the cuttings moist till rooted, then give plenty of air. The present is the best time for the work.

3071.—**Preserving Geraniums through the Winter.**—*R. N., Glasgow.*—These may be preserved in the window of any warm room if the gas is not too strong. They require to be kept rather dry. Sponge the leaves occasionally.

3072.—**Potting Violets for Winter.**—When ought I to pot Violets for winter flowering?—K. C. H. [Now.]

3073.—**Potting Camellias.**—Ought I to re-pot a Camellia now? The buds are well formed, and it has made a lot of new growth.—K. C. H. [No; wait till it has done flowering in spring.]

3074.—**Propagating Mulberries.**—How can I best propagate a Mulberry tree, as I am expecting a quantity of silkworms next year?—R. W. [Your best plan would be to buy plants from some good nursery, as if you propagate them yourself they will be too small to be of any service to you next year.]

3075.—**Weeds on Lawns.**—*Wm. H.*—How may I eradicate these without hand-picking? [Put a pinch of salt in the hearts of them at intervals of a few days, or try Watson's lawn sand.]

3076.—**Edging Beneath Shrubs.**—I have some walks overgrown by shrubs; would you kindly inform me how I may form an edging, the shrubs having caused the Grass to die? I cannot procure rock-stones for the purpose.—WM. H. [Plant Ivy and keep it pegged down, or St. John's-wort and Periwinkles will answer your purpose.]

3077.—**Watering Spiræas and Dielytras in Winter.**—*Mrs. D.*—The soil should not be allowed to get dust-dry, neither should it be kept wet until active growth commences.

3078.—**Growing Asparagus.**—Will Asparagus grow profitably north of London? Is a gravelly sandy soil in Hertfordshire suitable?—E. S. [Yes, if the ground be well enriched with stable manure or night soil, and it receives a good dressing of salt. Manure in winter, and plant in March.

3079.—**Moving Rose Trees.**—Can Rose trees be removed in September without its proving fatal to them? MRS. F. [Yes, if the weather is open.]

3080.—**Tenant's Right to Flowers.**—Can flowers in pots and boxes be removed from a garden without the landlord's permission if said plants were purchased by the tenant?—MRS. F. [Pot plants and those in boxes of course can be taken away, but trees and shrubs permanently planted cannot legally be moved without the landlord's consent.]

3081.—**Sowing Poppy Seed.**—When is the best time for sowing double Poppy seed?—Y. B. [March and April.]

3082.—**Bulbous Plants for Dwelling House.**—Are there any bulbous plants suitable for dwelling house culture in Scotland which come into flower after the Hyacinths?—J. B. [Tulips, Roman Narcissi, Squills (Scillas), Lilies, Vallotas, Triteleias, Anemones, Tuberous Begonias, Lachenalias, Gladioli, and many more. Procure a good bulb catalogue.]

3083.—**Runner Beans with Curled Leaves.**—*D. Moor.*—The leaves have been attacked by caterpillars, and the plants have evidently suffered from drought.

3084.—**Uses of Cocoa-nut Fibre.**—*H. S. Y.*—This is useful material in which to plunge bulbs during autumn and winter and plants in summer. It is also useful as a mulch for flower beds, and it will help to lighten heavy soils. Its great drawback is that it harbours insects to a great extent.

3085.—**Grape Vine Out-of-doors.**—I am thinking of planting a Vine against an ugly, bare, wooden fence, 6 ft. high, in an angle facing south and west. What is the best and most likely kind to ripen its fruit in such a position? Should the fence be tarred over first? and what is the proper time to plant?—NOVICE. [Royal Muscadine is as good as any. Plant it now or in March. You may tar the fence to preserve it if necessary.]

3086.—**Road Sand for Clayey Soil.**—*C. J. W.*—This is an excellent thing for clayey soil, especially when swept from streets in towns.

3087.—**Chemical Manure for Fruit Trees.**—Can Clay's fertiliser be used instead of stable manure for fruit trees? and at what time of the year should it be applied?—C. J. W. [Yes, but it is not nearly so good as stable manure. Apply it as a top-dressing with some fresh tufty loam in spring.]

3088.—**Slugs in Vegetables.**—I have about 150 to 200 Savoys, and also some Cabbages, almost full grown, and some with very fine hearts. Nearly all the leaves are riddled through like a sieve. On looking into the hearts I have discovered several large slugs and hundreds of black eggs. Can you give me a remedy to destroy them so as to save the vegetables?—DENTIST [It is as well to persevere in hand-picking the caterpillars from the Savoys, as those destroyed now will lessen their numbers next year; but when they are so badly infested there is little hope of making the present crop usable, that it would be well to cut them and give them to the pigs. If the stalks are left, the earth between them stirred up deeply with a hoe and some short manure spread among them, they will break out again, and the next crop, although smaller in size, will most likely be clean and free from insects.]

3089.—**Cutting Leaves from Strawberries.**—Some people cut all the leaves, &c., close to the ground from their Strawberry plants at this time of the year. Is this a good plan?—CANDELLUS. [No; remove all runners and dead leaves, and cover the ground with some well-rotted manure.

3090.—**Soil for Fuchsias.**—What is the proper sort of soil for Fuchsias? and the proper time to re-pot the same?—HOROLOGICAL. [Turfy loam three parts, rotten manure or leaf-mould one part, and a little road sand or oyster shells broken up fine. Re-pot when the pots are full of roots, but you would not require to pot any till spring.]

3091.—**Begonias.**—*M. S. P.*—The name of the smallest of the two Begonia leaves sent is Begonia parviflora. It can easily be propagated in a similar manner to the Fuchsia; care must, however, be taken not to overwater the cuttings; being of a succulent nature, they are very liable to rot off. As your plant is now fading, all that you can or need do is to keep it dryish at the root, and safe from frost during the winter. Then in the spring repot into good soil, and treat in a similar manner to a Fuchsia, the only difference in the culture required being that the Begonia does not want quite so much water at the root. The larger leaf sent was smashed beyond recognition.

3092.—**Wellingtonia gigantea.**—*Pansy.*—We cannot recommend the Wellingtonia for planting near London or other large towns; as a rule, it does not thrive well unless it is quite away from a smoky atmosphere.

3093.—**Twelve Early-flowering Single Tulips.** *Gang Forward.*—Duc Van Thol, Bacchus, Commandant, Kaizer Kroon, Pottebakker white, do. yellow, Kanarie Vogel, President Lincoln, Proserpine, Cottage Maid, Silver Standard, Rembrandt.

Clifton—The firm you refer to is thoroughly respectable. Neither we nor they could read your signature. The goods were sent per post to the name of "Morfau," and returned to sender as "not known."

Names of Plants.—*J. R. G., Warwick.*—Cornflower (Centaurea cyanus).——*Young Botanist.*—2, Lycopodium inundatum; 3, Lycopodium clavatum.——*Ramalho.*—The Apple is Summer Haglo.——*Oblidge.*—Hibiscus syriaca.——*H. L. A.*—Francoa sonchifolia.——*Ashtead.*—Fuchsia Earl of Beaconsfield, apparently.——*J. D.*—1, Deutzia gracilis; 2, Cytisus racemosus; 3, Azalea amœna.——*Arthur Smith.*—If you send shoots of the trees we can probably name them, but we cannot do so from single leaves.——*P. S.*—Impatiens glandulifera.——*Ashtead.*—Statice atifolia.——*M. E. R.*—1, Polypodium vulgare cambricum; 2, P. vulgare.——*Constant Reader.*—Some kind of Onion plant, but we cannot say which from a leaf.——*Mrs. D.*—Eucalyptus citriodora. It will only stand the winter in very warm sheltered localities in the south of England.——*Saxon Deyne.*—Gypsophylla paniculata.——*J. S. A.*—1, Sedum album; 2, Geranium Endresi; 3, Campanula racunculoides.——*F. Grant.*—We cannot name Pansies. Send Beans to Sutton's, who have the means of comparison.——*F. W. B.*—Verbascum nigrum.——*B. F.*—The Hoary Sheep's Fescue (Festuca ovina).——*A Reader.*—From appearance of leaves sent, seemingly a Cratægus of some kind, but cannot tell which without flowers.——*D. Moor.*—Giant Knotweed (Polygonium cuspidatum), a hardy Japanese perennial.

QUERIES.

To Querists.—*All questions are inserted or answered in these columns free of charge, provided the following rules are observed:* 1.—*Write clearly and concisely on one side of the paper only.* 2.—*Use a separate sheet of paper for each query.* 3.—*Give full name and address, with any* nom de plume *or initials you may wish used in the paper. Questions only of interest to the persons asking them should be accompanied with a post card or stamped addressed envelope for reply.*

3094.—**Plants for Greenhouse.**—I have built a lean-to greenhouse against a south wall in east London, 14 ft. by 6 ft., and have grown during the summer Fuchsias, Geraniums, Balsams, and Coleuses chiefly. I should like to know what quick-growing plant I could grow against the wall, scented preferred; what heat I should require for wintering flowering plants as Cinerarias; and what to do with old Fuchsias, Balsams, Geraniums, and Coluses.—E. P. M.

3095.—**Cactus not Flowering.**—My Cactus never flowered though potted as directed. Please give a list of those that flower freely.—S. M. G.

3096.—**German Ivy.**—Can any reader tell me where to get Ipomœa hederæfolia, sometimes called German Ivy? I have asked for it at some of the leading nurseries without success.—K. M.

3097.—**Imperfect Fuchsia Blooms.**—Can any one suggest the reason of the flowers of Fuchsia Rose of Castile cracking around the neck? I have grown several plants of it for the last three years, but have never had perfect flowers. They are grown and flowered in a cool greenhouse, and watered occasionally with weak sheep manure water. What is the best compost to grow Fuchsias in? and should they be placed out-of-doors to ripen the wood before flowering?—W. W. MARLER.

3098.—**Prickly Comfrey.**—I was intending to plant Prickly Comfrey (Symphytum asperrimum) to help to feed an Alderney cow, but I am told that cattle do not like it, and will not eat it unless they are half starved. I can only spare a small plot of ground. Ought I to plant Prickly Comfrey or Lucerne (Medicago sativa)? The latter I know gives an abundant crop, and may be frequently cut as green food. According to some reports I have read, the Comfrey, however, yields even more abundantly. I shall be glad to have advice on the subject.—C. W.

3099.—**Climbers for South of England.**—Will any reader tell me the names of quick-growing flowering evergreen climbing plants suitable for the wall of a house facing south, but rather exposed to east winds, in the south of England near the sea?—M. B.

3100.—**Scarlet Runner Flowers Dropping off.**—I want to know whether this can be prevented. I have a large quantity of healthy plants blooming well, and not an insect or grub to be seen, but the flowers droop and drop off without setting. On observing and searching closely I found that bees, both hive and humble, instead of entering at the front in search of honey, perforate the flower at its junction with the calyx, and drill holes all round with their probosces; flies follow suit, and this I take to be the cause. If any one can tell me of a remedy I shall be obliged. Some powder or odour which bees do not like might answer the purpose.—D. Y. N.

3101.—**Diseased Peach Trees.**—For the last three years my Peach trees under glass have been attacked by a disease, and though I have tried a great many authorities in such matters have hitherto not heard of any cure for it. Mr. Rivers told me to hunt for beetles, and said my experience showed them to cause the disease. I found the beetles, and so effectually cleared them out that I have not been able to find one this year, yet the disease is worse than ever, and I have just learned that though at Blickling they are swarmed with the same beetle they have not the disease. Will you kindly interest yourself in this matter, and give me any information you may obtain?—JOHN S. BOLTON.

3102.—**Autumn-planted Potatoes.**—Will some one who has practised autumn Potato planting tell me how to proceed, as I wish to try it? Full particulars as to manure, time of planting, &c., will oblige.—G. R.

3103.—**Management of Fern Case.**—I have a Fern case of which the dimensions are: length, 3 ft., breadth, 18 in., height, 38 in. The back and ends are boarded up, the front is of glass, and the top also. Which will be the best way to get the Ferns to grow out from the back and ends? I have a small one made in the same way, the Ferns in which grow very well with wire netting taken round it, and Cocoa-nut fibre and sandy loam put between the wire and the back. Can any one suggest anything better? My next question is, what will be the best way to heat it in winter?—A NEW SUBSCRIBER.

3104.—**Mosquitos in Houses.**—My house in Natal is infested with mosquitos coming from the conservatory. Can any one assist me to remove or mitigate the pest? I have tried burning sulphur, but without any good result; neither has Tobacco smoke.—DURBAN.

3105.—**Propagating the Gum Cistus.**—Will some one kindly tell me when and how to propagate this plant?—E. E. C.

3106.—**A Floral Police.**—Your correspondent "Ailenroc" asks if Broom tied round Gooseberry bushes keeps off the caterpillar. Possibly it may; I know not, but I have not referred to his question for the purpose of answering it, but because it calls attention to a branch of study which has not been fully prosecuted, I believe. Does there not exist an efficient floral police beneficently provided by Nature for the protection of the vegetable world, and furnished by members of its own constituency? We are told that in law there is a remedy for every wrong, and in medicine an antidote for every poison, though not all are at present known. So I believe there exist plants which are respectively protectors and guardians of the various other plants in the botanic world. One of these floral police is well known to many, viz., the common Pyrethrum, and I have found it of incalculable value in my kitchen garden. I wish that someone would give an article on this subject, and refer me to any book in which Darwin or Lubbock may have treated on this question. I have just heard of a case where a crop of Mustard completely cleared a field of wireworm.—LLEWELLYN.

3107.—**Plants for Small Garden.**—I will be obliged if any reader of your valued paper will advise me of the most suitable plants to grow in a piece of ground (in back-yard) about 10 yds. square; it faces south, but is partly shaded by yard walls. Also what flowers to grow in ground in front of house, facing north, and in shade the most of the day; the ground is about 6 yds. long by 3 yds. wide. When should I plant the flowers? I may mention that the ground is of a stiff clayey nature, full of worms, and has previously been covered with Grass. If suitable I would like to grow a few Roses, Mignonette, &c.—sweet smelling plants. What would be the best climbing plant to train up the walls? and when shall I plant it?—NORTH SHIELDS.

3108.—**Leafless Mulberry Trees.**—A Mulberry tree which has been in our garden for twenty years has this year no leaves within more than 3 ft. of the ends of the branches, and has no fruit instead of the usual abundant crop. We hear that a neighbour's tree is in the same condition. Is it from any preventable reason?—M. N. O.

3109.—**Keeping Potatoes.**—I shall be glad if any of your readers can inform me the best way to keep Magnum Bonum or other late Potatoes till end of May.—M. A. C.

3110.—**Colouring Grapes.**—I have seen hothouse Grapes very black, but without any bloom, and having the appearance of having been dipped in some preparation. I shall feel obliged if any one can tell me how this appearance is obtained.—R. B. M.

3111.—**Climbing Roses.**—I have just removed into a new house facing west by south, and am wishful to train up some three Rose trees, a white one under window to go directly up each side, and a red one on either side. Will some one name varieties most desirous, and soil to plant in, and any other useful information with respect thereto? I would mention that there is a border, 15 in. wide goes up in front of window, and that there is clay at 8 in —RHODODENDRON.

3112.—**Iris Seeds.**—I have just gathered splendid seeds of the Iris. Will some practical friend say how to treat them for producing future bulbs?—CANDELLUS.

3113.—**Plants Becoming Weak and Drawn.**—I should like to know how to remedy an evil that is with me. I live in a close confined place in the town, and being fond of flowers, for years have been trying all sorts of plants in pots, but have received no success. I have this year constructed a small window greenhouse, but this fails, and I cannot get a bloom on a plant, and all the plants get weak and spindly; even the plant Stonewort, commonly called Stonecrop, is becoming as fine as a hair, while some of my neighbours will have strong healthy plants. Now how to remedy this I cannot tell, for it confounds me. Can any one inform me what causes the production of green Moss on the mould? If we continually wash the pots they become covered with this green, and the wooden boxes the same; this will grow if the plants will not. I read in GARDENING what people can do with stone yards and close confined places, but as for myself all is disappointment. I may add we have the sun in our yard from eight in the morning till twelve at noon, and longer in some parts, but where the plants are the time stated?—CONSTANT READER.

3114.—**Club in Cabbages.**—In my garden I am much troubled with club in Cabbages and Cauliflowers, which is caused by a small white insect. This summer, even when the Cauliflowers are half formed, the leaves flag and further growth is stopped, and when taken up, there are about a dozen lumps from the size of a Nut to a man's finger. I generally bastard trench the ground, as it is only shallow soil about 15 in. deep. In last week's GARDENING a correspondent recommended dipping the plants in soot and earth mixed to a paste when planting. Could clubbing be prevented by watering the plants with a solution of nitric acid, say 2 oz. to 2 gallons of water, or a strong solution of salt and water? Can any one give me some information how to cure this pest? I should be very grateful, as I have been struggling with it for four or five years.—PERSEVERANCE.

3115.—**Planting Currants and Gooseberries.**—I am clearing off my garden some old Gooseberry trees. Will some one inform me how to prepare the ground for new ones? also what sort to plant, and when to do it? I should like to have them as espaliers also. Can old Currant trees be put in the espalier form?—J. HORWELL.

3116.—**Pruning Ladder.**—Can any one tell me if there is any place in England where the double ladder used so much in France for pruning trees, can be procured? They are about 14 ft. high, broad at the base and narrow at the top, with hinges and light to carry.—ROSALIE.

3117.—**Water Snowdrop.**—I once grew this with great success in an aquarium, but have not since been able to find a dealer with any knowledge of the plant. Can any one assist me?—J. G.

3118.—**Heating a Brick Pit.**—I have a large brick pit, about 20 ft. by 8 ft., and wish to utilise it for keeping bedding plants, &c., during the winter. What is the best means of keeping the frost out? Would a petroleum stove answer? and, if so, whose would you recommend? The winters are rather severe here, and gas is not available.—J. H. W.

3119.—**Unfruitful Grape Vine.**—I have a Grape Vine trained against a wall which faces the north. For several years the fruit has been blighted with mildew. It is always damp, as the waste water from the pump runs near the root. Is there any cure for it? or would any kind of Plum succeed better?—T. C.

3120.—**Fuchsia Buds Dropping.**—My Fuchsias do not come into bloom; they appear healthy, and their growth is luxuriant; but when the buds have reached the point of opening they invariably drop off by the stem. Can any one give me the reason for this?—MCGILLICUDDY.

3121.—**Annuals for Profit.**—I possess a heated greenhouse and a cold frame, and as a source of profit I am desirous of cultivating a few annual flowers for the purpose of making button-hole bouquets. Will any one of experience kindly advise me as to which are the most suitable kinds to grow, and that would last well after being cut? Also when to sow them.—G. H. P. J.

3122.—**Hollow-stalked Celery.**—My Celery, a white variety, was planted early in July in a well-manured trench, and I have given it manure water several times. It is now from 2½ ft. to 3½ ft. high, wrapped in paper to bleach it, but the stalks are all hollow and tough. Can you or any reader explain this, that I may avoid such a disappointment in future?—R. S. VENABLES.

3123.—**Diseased Hollyhocks.**—My Hollyhocks have been totally destroyed this year by a fungus in the leaf. They began to be affected about the end of June, and there is neither leaf nor flower left. Can any one tell the reason, and how to guard against it in future?—J. L.

3124.—**Dressing Carnation Blooms.**—Will any one be kind enough to give me full practical directions on the art of dressing Carnation blooms for exhibition?—FLOS.

3125.—**Trees for Shelter.**—Will some one say what would be the best trees to plant—first, to break the force of the east winds, and, second, for ornament—along a wall 32 ft. long and facing south? They would, of course, be required to grow considerably higher than the wall. The ground inside the garden is 3 ft. higher than the road. Would fruit trees, such as Apples, answer he purpose?—J. W.

3126.—**Mites in Drying Paper.**—Can any one tell me how to destroy and prevent mites which are developed in the drying paper which I use for pressing botanical specimens?—S. A. S.

POULTRY.

Vermin in Geese.—I keep a great number of geese, which are so infested with vermin of different kind, that I am at a loss to know what to do. Can some reader give me good advice to help me out of my difficulty?—LUPUS.

Chicken Dying.—Could any reader of GARDENING tell me the reason why one of my Leghorn chickens have died? It was hatched about the beginning of July, and was healthy till about ten days ago, and then it pined away and died. I gave it some Parrishe's Chemical Food, and fed it with bread and milk with Corn mixed in, but it was no good. The reason why I gave it Parrishe's Chemical Food is as follows: My next-door neighbour has a large number of chickens; some died off, and I was asked if I could do anything. I recommended the food, and the chickens quite recovered, but mine did not. I can see no apparent reason for the chicken having drooped so.—W. KIDDLE.

Fowls with Coughs.—Can any of your readers tell me of a cure for a nasty shrill cough my poultry have had for some months? It seems to trouble them most when eating grain. We have tried damping it, but that makes no difference. It does not affect their appetites or looks, but one hen had it so badly, we thought it better to kill it.—F. H. A.

Pure Bred Hamburghs.—What are the characteristics of a pure bred speckled Hamburgh cockerel? and of a pure black Hamburgh pullet?—WOOD B.

HOME PETS.

How to Keep Doves.—I have kept a pair for some time, and find the following treatment of them answer perfectly. Give them a wicker cage large enough to allow them to exercise their wings as much as possible, or else let them out every day for a flight in a room; this will also tame them. Clean out their cage every morning regularly (I find a long-handled plate-brush will do this most effectually with plain water, and twice a week soap and water). Fresh seed and water every day is most important, and they like dry bread. I feed my doves on Hemp seed, Buckwheat, and canary seed mixed, and in summer I give them occasional green food in the shape of Chickweed or blades of green Corn. Keep them from cold and draughts, damp and heat. I hang mine out-of-doors all day when fine, but take them in at night. A potted-meat jar or dish is the best water vessel for them, as they can take a bath in it. If troubled with vermin, sprinkle some Hardeman's Beetle Powder among their feathers, which is harmless to taste and touch. Keep them out of the way of dogs or cats. Doves lay two eggs at a time, which produce a pair of birds, and these, when old enough, should be mated. My doves, though no longer young, lay assiduously from early spring to autumn. When hatched, put in the cage a finely chopped-up hard-boiled egg mixed with a little dry bread or Hartz Mountain Bread for the parent birds to feed their young with. They are stupid birds, and the cock very "touchy" and easily provoked, but they can be tamed easily, and are devoted parents to their young.—K. C.

Keeping Jays.—Having caught two young jays under my Pea netting, and wishing to keep same in a cage, I should be glad to know the proper food to feed them upon?—J. V. M.

Birds in Fern Cases.—I have a large Fern case, 7 ft. square and 6 ft. high, well stocked with various Ferns. Might I with safety turn in among the Ferns, say, half-a-dozen canary birds? There is plenty of room, and the case is very well ventilated.—LIVERPOOL.

Book on Goats.—Can any of your readers inform me of the best shilling book on goats, and the address of the National Goat Society?—KID.

AQUARIA.

Stocking a Bell-glass Aquarium.—*Campion Dawson.*—Not knowing the contents of your propagating-glass, I cannot say the exact quantity of stock it will hold. The proportion of plants to fish must depend on the size of both, and upon the amount of confervoid growth allowed. It is best to have a few fish and see them doing well, and then add to their number. Let the plants be well rooted, and encourage the growth of confervæ, and moderate the amount of light. The cloudy condition of the water arises from floating particles of vegetable matter, produced by too much light. See No. 60. In No. 67 you say you do not feed your fish. Give them vermicelli and small red worms.—T. CHADBURN.

Plants for an Aquarium.—"Ferry Hill, Durham," requires too much for his aquarium; he wants to make a shrubbery of it. I would recommend him to read Shirley Hibberd's little book on the "Aquarium and its Contents," published at Groombridge & Sons, Paternoster Row, where he will find the best means of management.—HYDROUS PICCUS.

—— *G. A. W.*—In your case we think you had better make a fresh start, and begin by setting your plants well rooted. Make a small box of thin wood about 1½ in. deep inside. Fill 1½ in. deep with well-washed sand. In this plant Vallisneria and Anacharis, and then cover the surface with small pebbles. Place this in the centre of your tank bottom on the glass, and cover the rest of the bottom with shingle or small stones. Let the plants get rooted, and if there is a bit of spar on the bottom, it will soon be covered with confervæ. Then introduce the stock, beginning with few. If your fish come to the surface and gulp in atmospheric air, you will know something is wrong, and they are too crowded, or too hot, or something equally wrong.—T. CHADBURN.

—— Can any reader of GARDENING answer the following: I have a small aquarium with wood ends and sides of glass, ends and bottom lined with zinc. I should like to have some water plants; would zinc hurt them? What kind of plants are most suitable for an aquarium about 8 in. deep?—STICKLEBACK.

Making Aquariums.—I have lately seen several hints in GARDENING as to making aquariums of various sorts, but which are unsatisfactory, inasmuch as they do not state (as the old cookery books did) how to "catch your hare." In other words, I would ask where to get, what to pay, and how to apply solder. My own plumber would, I feel convinced, send in his "little bill" at once if I was to ask him.—GUDGEON.

Self-acting Fountain.—I am anxious to know how to construct a self-acting fountain for an indoor Fernery.—FOUNTAIN.

Cement for Aquarium.—I would like to know a suitable putty or cement to fix glass in an iron frame aquarium?—A CONSTANT READER.

Gold Fish.—Can any one tell me the reason that the gold fish and minnows in my bell-glass aquarium go so much to the top of the water, not lying lazily along the top as if weak and languid, but with their mouths pointed upwards, swimming round and round? I have green weeds and molluscs in the glass, and often renew the water, keeping it clear; the glass is also shaded from the strong light. Also where can Robert's food for gold fish be procured?—UNA.

Honeydew.—"H. D." persists in holding to the belief that honeydew is a plant product, and not the excreta of aphides. How is it that it is never found totally dissociated from the aphis, which seem to have the power to eject it a long distance? Further, it is never found on the undersides of leaves, and if it were a natural exudation, why should that be so? It is also always found on leaves that are beneath the points occupied by the aphis; and as now may be seen on some Rose leaves here, the excreta has passed into a decomposed mouldy state, that will wash off and leave the surface of the leaf quite intact. It is very cool on the part of "H. D." to call upon "Sir John Lubbock and other writers to correct their erroneous impressions" on this matter because he chooses to hold they are wrong and he is right; but his believing as much does not prove it, rather in his case it seems to prove the reverse.—A. D.

Killing Slugs.—In my note in a recent issue of GARDENING ILLUSTRATED under this heading there is a mistake likely to mislead, viz., Gas lime should have been Lias lime, as gas lime would be likely to taint anything it touched.—H. SLINGSBY, JUN.

TUBEROSE GROWN IN THE OPEN AIR NEAR LONDON.

TUBEROSES.

OUR frontispiece this week represents a spike of flowers of an unusually well-grown Tuberose produced in the open air in a garden near London. Though a native of the East Indies, strong imported bulbs of the Tuberose will flower well in the open air during the month of August in warm soils. It must, however, be remembered that, like Hyacinths and similar bulbs, Tuberoses will not flower so well the second year as they do the first year. Sufficient strength to flower well is only found in bulbs grown and matured under the sunny suns of Italy and France, from whence most of the Tuberoses grown in this country are imported. For greenhouse culture Tuberoses are greatly prized on account of their wax-like perfumed flowers. London bouquet makers especially seek for blooms of the Tuberose on account of their white, waxy appearance, their durability, and perfume. Thousands of bulbs are imported yearly from France; one grower for market imports from 25,000 to 30,000 bulbs annually. These are divided into batches, in order to obtain as long a succession of bloom as possible. The beginning of November is the time when the first batch is usually started. The bulbs are potted in small pots and placed in a warm house supplied with a good bottom-heat bed. When the shoots have attained an height of 9 in. or 10 in. the plants are potted into 6-in. pots, and pushed rapidly into bloom. As the spring advances less bottom-heat as well as top-heat are required to bring the plants into bloom, and after April they are grown in pits and frames fully exposed to light and sun, and abundance of air is given in fine weather. Forced plants when in bloom are placed in a cool house to harden them before being cut, in order that they may stand longer when sent to market. In the best of the season, which is from May to August, good plants often bear as many as six large and fragrant blossoms, but during dull weather two or three inferior ones only are produced. Light, rich mould, to which plenty of sand has been added, is the kind of soil used for Tuberoses, but they will succeed in any good garden mould. Nearly all the year round a good supply of Tuberoses may be obtained by good management. The flowers from which our illustration was prepared were sent to us by Mr. Ware, of Tottenham. The botanical name of the Tuberose is Polianthes tuberosa.

Carnivorous Insects.—Being busy with my Tobacco water and brush in the interests of a fly-infected Fuchsia, I became aware of the presence of a tiny creature of about ¼ in. long, whose action is best described by likening it to that of a leech—the same grip of the tail and blind, helpless manœuvring of the head. Removing the leaf for further examination under the magnifying glass, I came to the conclusion from the formation of the head that he was carnivorous, and, offering him an aphis, it was seized with avidity, and in about ten minutes was sucked dry, the dried-up skin (similar to those to be seen on fly-infected plants) being then tossed away. As my new friend has polished off twelve aphides and a small green caterpillar since the morning, I shall be glad to know more about him, as the introduction of a few into a conservatory might be worth a trial. The head and thorax are translucent, as, indeed, more or less, is the body. The body is white and the back fawn-coloured, with brown markings, the body being in six segments. If the insect and its habits, however, are not very generally known, this letter may be interesting to your readers, and also serve to open the question as to whether it is well to kill friend and foe alike by wholesale syringing.—H. H.

FRUIT.

MAKING BORDERS FOR FRUIT TREES.

LAND naturally porous, and indeed often too dry in summer, is not unfrequently in a waterlogged condition in winter. Therefore, all properly made fruit borders should have a drain along the front, with a good clear outfall that would be free in times of flood; in some gardens it would only be in times of sudden downpour in autumn or winter that the drains would be required, and in all cases the sooner all excess of water in the land is passed away the better, as it lowers its temperature so much. In preparing borders for wall trees, width, and in some measure depth, must depend upon the height of the wall.

Width of Border.—A tree that is expected to cover a large space must be allowed a correspondingly wide root-run. Thus, in most gardens, it has been the custom to allow the wall borders to have the same width as the height of the wall, and it should be over rather than under; and then the front might be cropped with dwarf-growing vegetables or salads. These borders are so valuable for early crops that they cannot be dispensed with. The present time, before the autumn rains set in, is the best time to make new or remake old fruit borders. The work can be done more expeditiously when everything works cleanly. Another and more important advantage is, it gives a period for the soil to settle before planting; and it is a great advantage to the well-being of all deciduous trees to be planted by the end of November.

Depth to Plant, &c.—For a tree that is expected to live to a good old age, to lead a steady, regular, and consequently a fruitful existence, not excited by stimulants, or unduly crippled by poverty through being confined too much in its feeding bed, 3 ft. may be taken as a good average depth. In some places where the subsoil is very inferior a few inches less will suffice, and the border should also be raised a few inches above the natural level. No doubt good crops of fruit have been grown in shallow borders, but in this case more care and labour are involved; and, unless there be a positive necessity through the subsoil being of a cold, wet character and the neighbourhood low and difficult to drain, a depth approaching to 3 ft. will give the best result, if lasting fruitful powers are sought in combination with fully developed trees. Where chalk abounds, 5 in. or 6 in. of it placed in the bottom and rammed down firmly makes a good foundation; or 3 in. of tempered clay placed on top of the clay, and well kneaded and trampled in, and rolled when approaching dryness, also forms a good hard floor. A layer of concrete answers the same purpose, or the bottom may be paved with tiles or bricks laid on cement; in short, the materials that can be most easily obtained should be used in each case. The bottom of the border should have a fall of 1 in. in 8 in. or 10 in. to carry off the water to the drain in front, which should be made at the same time the border is excavated, laying the pipes along its front and a few inches below its level. The soil for the different kinds of fruit will not vary much in the same locality.

Peaches should have a good sound loam, neither heavy nor light, with as much fibre in it as possible, and if soil of this quality and texture cannot be had, secure the best and nearest approach to it. From 4 in. to 6 in. thick of the top of the sheep pasture is the soil sought for by the cultivator, and where success is aimed at it is a mistake to refuse the means to do things properly. Apricots will thrive in rather a lighter soil than Peaches; and Cherries, again, thrive best in soil of a gravelly or a stony nature rather than heavy or close. Plums, Pears, and Apples succeed very well in well-drained mellow, loamy soils. S. W.

Cherries in Small Gardens.—The May Duke and the Morello are the kinds best suited for a small garden; they may be grown in the bush form on the Mahaleb stock or fan-trained on a wall. In a warm corner against a wall the May Duke comes in early and often bears profusely. Not far from where I am writing there is a May Duke Cherry against the front of a cottage; I believe when it was planted little or no preparation was made for it, and the immediate space over its roots is partly paved and gravelled; yet the crop of fruit that the tree annualy bears is something marvellous. No doubt the soil is suitable, and the hard, firm surface has much to do with its prolific habit. What I have seen in this way leads me to the conclusion that there cannot be a greater fallacy in fruit culture than to suppose that it is necessary to dig and delve over or amongst roots. It may do no harm the first few years, or rather, I should say, no perceptible injury is done, but if anything beyond a surface cultivation be carried on it must drive the roots downwards. When once a tree settles down into a bearing condition the roots should not be disturbed in any way, and no implement beyond the hoe should be used during summer, and where a little mulching can be put on in spring the use of the hoe may become unnecessary. What we require in a fruit tree is a medium annual growth—in fact, just af air amount of extension in order to keep up the tree's health and vigour. And this is best secured by a firm soil and light annual top dressing, but no manure should be placed in contact with the roots, as the chances are the growth will become too gross, and if so, farewell to fruit bearing till the tree has been lifted and root-pruned. It is better to avoid the necessity for this if it can be done, which it may be, by a fine soil and judicious summer pinching. The Morello is a very prolific Cherry, seldom fails to bear, and is especially adapted for a north aspect. In September, when the fruit is ripe, it is sometimes worth 1s. per lb., and the trouble required is but small. The fruit is produced on the young wood, and the disbudding and pruning recommended for the Peach are quite suitable for this Cherry. One of the chief faults in its management, observable almost everywhere, is laying in too much wood. Overcrowding the wood does not produce more fruit, but the reverse, and it tends also to debilitate the tree, and is often the cause of branches dying off in summer.—H.

Pruning Peach Trees.—As soon as the fruit is gathered, all the small shoots should be unnailed, and all the fruiting wood cut back to the point whence the young wood starts; unless there are vacancies to fill up, there is no occasion to wait for the falling of the leaves to do this, as I believe the sooner this is done in autumn the better the young wood will ripen; but shortening of the young wood had better be delayed till February for two reasons: First, because after the buds have swelled a little there will be no difficulty in distinguishing the flower-buds from those that produce wood only, and it is important to cut each shoot back to a wood-bud, as without a leader the fruit, even if it set, will be flavourless; and secondly, leaving the shortening till the buds are pushing, and leaving the tree unnailed till the last moment, has a tendency to retard its flowering, and a few days' delay in the case of severe weather sometimes saves the crop. The young wood should be cut back one-third, one-half, or two-thirds, according to its strength and firmness; always cut back to well-ripened wood.—E.

Sawdust in Gardens.—I have used a great quantity of this mixed with manure for some years in my garden near Harrow, where be it known the soil is a hard yellow clay. It tends greatly to loosen the soil and make it work easier, and such vegetables as Potatoes, Radishes, &c., are finer and cleaner, and also less affected by disease in wet seasons. I also think that it is the resin in the wood (sawdust) which keeps the long thick earthworms away, as I have also found that they are very scarce where the sawdust is used.—BORONIA MEGASTIGMA.

Caterpillars on Cabbages.—I am informed that covering Cabbages with the fronds of the common Bracken (Pteris aquilina) is a certain and easy way to get rid of caterpillars

My informant made a trial of the remedy himself. and he assures me that in one hour after the Bracken fronds were laid on not a caterpillar was to be seen. Elder leaves are said to be equally efficacious.—E. M.

VEGETABLES.

Easy Way of Growing Horse-radish.—Is the plan of growing this by placing a common round drain-tile with it, and set 2 in. in the earth, filling the tile with fine earth, and planting a set near the top of the tile and 10 in. above the surface, sufficiently well known? It is an admirable plan; digging for the product is saved, and a fine clean stem is the result.—V.

Pruning Tomatoes.—Many find much profit in pinching back the branches of Tomatoes, and it is a good practice when judiciously done. It may, however, according to an American writer, be overdone, and injury be the result. In the first place it is of no use to attempt it after the flowers have fallen. The idea is to force the nourishment into the fruit at the earliest start, for it is at that time that the future fate of the fruit is cast. A few leaves beyond the fruit is an advantage. It is only the growth that is to be checked; and then much damage is done by taking off the leaves as well as the fruit. The Tomato plant needs all the leaves it can get; it is only the branches that are to be checked in their growth. No one who has not tried it can have any idea of how valuable the leaves are to the Tomato plant. One may for experiment take off most of the leaves of a plant, and he will find the flavour insipid and in every way poor. Of course it is the peculiar acidity of the Tomato that gives it so much value to all of us, but the acid from a Tomato that has ripened under an insufficient amount of foliage is disagreeable to most tastes.

Tarragon.—This is so constantly required in a green state, that some special care is necessary to ensure an abundant supply of it. Its roots should, therefore, be potted in October, and introduced into a greenhouse or warm frame heat as required for the winter supply. Out of doors, when the soil is not naturally favourable to its growth, it should be mixed with a few barrow-loads of road scrapings and thoroughly decayed mortar-rubbish, and the beds should be raised a little above the level of the surrounding surface. By cutting portions of the plants for drying at different times we are never short of a supply of it.—J. G.

Town Gardens in Autumn.—Just now, when Oaks are turning brown on hill-sides and Chestnuts are shading off into yellow and russet; when Grapes are purpling on sunny walls in suburban districts all around us; when the Chilian Passion-flower drapes our warm walls with its golden egg-like fruits, and the Virginian and Japanese Creepers are ablaze with crimson and gold, we long to see our town gardens made more interesting by the intelligent use of trees and shrubs which assume varied tints as their leaves decay in autumn. And we have a great wealth of material for this purpose, if we will only use it in the right way. The Sugar Maple (Acer saccharinum) is one of the most beautiful of all autumn trees; so is Pavia flava, the foliage of which, late in the year, is of the richest shades of orange and russet, while the leaves of the common Scotch Laburnum, when they die off in autumn, are the colour of burnished gold. With these might be associated that hardiest and most graceful of all trees, the silvery-barked Birch, of which we have now numerous distinct forms. There are few trees in autumn more effective when planted among other kinds than Birches, and this may be seen any afternoon in Kensington Gardens, where their slender trunks stand out as clear and as bright as shafts of burnished silver, and their graceful branches droop with spray-like elegance. With these we might associate the Liquidambars and the double-blossomed Cherries, the leaves of which die off bright yellow, and by wreathing the stems and branches of our ornamental trees with Virginian Creeper, Grape Vines, Wistaria, or green and variegated Ivies, additional foliage effects may very readily be obtained. Another source of beauty in autumn is found in our ornamental berry or fruit-bearing trees and shrubs, such as the Mountain Ash, large fruiting Hawthorns, the yellow and scarlet-fruited Siberian Crabs, Cotoneaster frigida, C. Simmondsi, Pyracantha japonica, Aucubas, and many others, not forgetting the common Arbutus, bearing its bright orange-red Strawberry-like fruits among glossy leaves and Lily-of-the-Valley-like flowers. How is it that the large fruiting forms of Cratægus are so little grown in town gardens? They are as hardy as the common Hawthorn, and their fruit and foliage are both larger and more distinct than those of that well-known variety. Some of the varieties of Berberis Aquifolium are very beautiful in autumn and throughout the winter; and the American or Ghent Azaleas are nearly as beautiful in the autumn, when their foliage is changing to crimson and gold, as in the spring, when covered with fragrant flowers. Pampas Grass and stately Yuccas, too, must not be overlooked, for both are useful and permanent. Those trees which remain fresh and green when others around them are changing into the "sered yellow leaf" are also useful, both for contrast and for enabling us to retain the freshness of summer as long as possible. To this class belong the Lombardy Poplar, the Ash, the Plane (just now the greenest of all town trees), and the Fig. This last-named tree is one of the best small-growing large-leaved trees for town gardens, its foliage equalling that of the Paulownia or Catalpa, while it is far hardier and makes a more luxuriant growth than either as a standard or trained on walls. The Fig is quite at home in deep rich soils, and it makes a good fence if trained and tied down occasionally, while its leaves remain fresh and green until the frosts cut them off late in autumn. On protected patches of fresh green turf we might have tufts of hardy Cyclamens, autumnal Crocuses, and Colchicums, which would look more beautiful among the herbage, the latter also preventing their delicate flowers from becoming splashed by heavy rains. One of the hardiest, showiest, and best of all autumnal flowers, however, is the Chrysanthemum, and it is to this plant and its innumerable varieties that we must look for bright autumnal floral displays in town gardens. That Chrysanthemums can be grown in town is demonstrated in the Temple Gardens, where we have annually fine displays of these flowers, both under canvas and in the open air.

ROSES.

NOTES ON ROSE CULTURE.

A good yellow loam, inclined to clay, is the best soil for Roses; this, well drained and trenched 2 ft. deep, with a mixture of rotted cow manure, will insure a firm, vigorous growth. To every barrowful of manure may also be added half a bushel of ½-inch bones. This will give a more lasting supply of nourishment to the roots. Planting may be done at any time between the fall of the leaf and the swelling of the buds in spring, though autumn planting is to be preferred to that done in spring. In any case the plants ought to be obtained early. During the dull season they are less liable to injury than at any other time in transit, and they can be laid in the ground in a sheltered place until the situation in which they are to grow is ready for them, and to which they should be transferred without undue exposure.

Pruning is an operation which requires judgment both as to manner and time. Newly-planted Roses should not be pruned until the points of the shoots have burst into leaf. The period of blooming will be somewhat later than with established plants pruned earlier, but good blooms may nevertheless be expected, and, what is more important, the future health of the plant will be promoted. In the case of dwarfs or standards, a cup-like form is the best shape at which to aim, each shoot springing away equally outwards and upwards from a common centre. Therefore, prune back to a bud pointing outwards, whether it be the second, third, fourth, or fifth bud from the base, in the case of an established plant, and afterwards, when the growth is more advanced, disbud all shoots having a tendency to unduly crowd the centre, or cross or interfere with the others. This is a rule which should guide the inexperienced not only in Rose pruning, but also in that of all other kinds of bushes. In the case of newly-planted Roses prune back to three, four, five, or even six buds from the base, bearing in mind what has been said. This applies to the larger section of Hybrid Perpetuals and others commonly known as standard, half-standard, and dwarf Roses.

Planting.—In planting dwarf Roses put the junction of the scion with the stock at least 1 in. below the general surface of the soil. The tendency of the stock to throw up suckers is thereby checked, and the emission of roots from the scion itself is greatly promoted. The sécateur is the best pruning implement for an amateur, though nothing can beat the knife for speed, precision, and cleanness of cut in the hands of a practical operator.

Insects.—Green fly is the greatest pest with which the Rose grower has to contend, and nothing is more effectual in the way of destroying it than Tobacco smoke, where its application is practicable. I have seen a hood made of oiled paper, stretched over a light wicker-work frame, placed over the plant, and by the introduction of the nozzle of the fumigator through a hole at the bottom the application of Tobacco smoke has been most effectually done. Fowler's Insecticide is also a useful composition for destroying green fly. There are likewise some species of caterpillar which in the earlier part of the season are pests to Rose growers. The best remedy for these is to nip them between the finger and thumb. Next to green fly, mildew is the greatest enemy with which the Rose grower has to contend. To cure this, when the sun has lost its power in the afternoon, damp the affected trees with the syringe, then, with the sulphurator or a dredging-box apply flowers of sulphur or sulphur vivum perfectly dry. Another way is to take 1 lb. of sulphur vivum, and put as much water to it as will work it up into a paste; it will be easily dissolved in about 3 gals. of water, and should be applied with a syringe, keeping the mixture well stirred. It is of importance to use sulphur vivum, which is more effectual than common yellow sulphur.

The tendency of modern gardening seems to be to isolate whole families of flowers into groups, and the Rose has doubtless so many charms of its own, that we cannot have too much of it, and a large bed of Roses in full bloom is certainly a grand object; but their beauty is short-lived, and I like best to see them in mixed borders, where, when in bloom, their charms are heightened by contrast with other flowers. Climbing Roses have a pleasing effect when associated with Honeysuckle in a hedge, or on a rustic porch, and in many unexpected situations and combinations which will readily suggest themselves.

B. S.

Carlisle.

Cuttings of Roses Under Cloches.—Cuttings of Roses are easily taken from September till the last week in October. Choose a well sheltered spot, at the foot of a wall if possible, and which can be easily shaded from the direct rays of the sun. Prepare the ground thus: First make it firm and level, then spread over it evenly 6 in. thick of short dry stable manure; over the manure place from 3 in. to 4 in. of sharp sand, the sand to be slightly moist. Prepare the cuttings in lengths of from 2 in. to 6 in. each, according to the strength of the shoots. The best cuttings are those taken off with a heel. The sections are made immediately below an eye. Cut off all the leaves to one-third of their length, the leaf-stalks to be left attached to the cuttings. Now press down the cloche on the sand, so as to leave the mark of its circumference, and within this mark put in the cuttings at about 1 in. apart, and to the depth of from ¾ in. to 1¼ in., according to their diameter. Then lightly syringe and cover over with the cloche. In winter fill up round the cloche with dry leaves, and cover with a mat in frosty weather. In favourable situations these cuttings may be planted out in May at 1 ft. apart. In less favoured districts it is well to leave them alone until June; then take off the cloche and transplant in October. Many of the cuttings put in in September and October should bloom in August next year. I have Roses now in bloom that were put in as cuttings last October under cloches. The cloches in France cost less than a franc each; the nurserymen here charge 2s. 6d. for them.—Ombu.

HYACINTHS IN BEDS AND BORDERS.

THERE is no better situation for the culture of the Hyacinth in the open air than a sheltered bed or southern border, with a sharp slope to the south; in any position it is important that the surface should be convex or pitched, so that no stagnant water in the winter can rest on the surface; thus made, the bed will be dry.

Soil and Manure.—The soil should be light, rich, and sandy. Though many assert that Hyacinths seldom do so well anywhere as under the influence of sea-spray, our experience proves that they grow as well without it; while it is equally certain that salt is a dangerous fertilising agent, unless for such decidedly saline plants as Seakale or Asparagus. If the soil be stiff and clayey, have it removed to a depth of 2 ft., and fill up with a mixture of leaf-mould, peat, and well-rotted manure, and if possible silver sand; in any case the soil should be rich and dry when prepared. In the place of horse manure, old cow manure may be used.

Planting.—The best time for planting is from the beginning of October to the latter part of December; if planted too soon the Hyacinth will be too forward before the hardest of the winter is past; if too late, the bulbs will be partially exhausted before they are put into the earth. By planting in succession through these three months, we have Hyacinths also in succession for several months in the spring. As to the manner of planting, perhaps the worst mode is that of dibbling in the bulbs, as the pressure of the dibble is apt to leave the ground hard, whereas the soil at the base of Hyacinths should be rather loose, so that the roots may start and grow away freely. When this precaution is neglected, we often find that the mass of roots lifts the bulb out of the ground. For planting make a shallow trench with hoe or spade 3 in. deep and of a uniform depth; place the bulbs at the bottom and replace the soil, pressing it firmly at the top. Sometimes 3 in. of soil are taken off the surface of the bed, and the place of the bulbs marked at distances of 6 in., 9 in., or 12 in. apart, 9 in. being a good average; place a small handful of river-sand for each bulb to rest upon, and return the soil. It is a good plan, perhaps, to place stakes to the bulbs before covering them, as if this be not done the bulbs are often staked through when the flower-stems need support; it is also a good practice to cover the beds over with 2 in. or 3 in. of Cocoa-nut fibre refuse, which renders the surface frost-proof.

Protecting the Flowers.—The bulbs need no more attention until the flower-stems are much advanced, unless very severe weather intervenes, when they should have a mat or some oiled calico thrown over them. Waterproof calico is also useful in very wet weather, excess of water, especially when iced by February frosts and March winds, being by no means good for Hyacinths, which will thrive all the better for being sheltered by a waterproof covering. Hyacinths in the open air hardly ever require artificial watering, the natural moisture of the soil and the strength of the manure mixed with it being sufficient to carry them through. Tie up the flower-stems as soon as they rise above the foliage, and have protection at hand, as sleety frosts may destroy the flower-stems during severe weather.

Treatment After Blooming.—After blooming, the bulbs, if expected to flower again, must be left undisturbed until the leaves wither or die of their own accord. The bulbs should then be taken up and dried in a stack for a week or two, and finally placed in the sun for a few hours, and the dry leaves pulled off. Offsets should be removed likewise from the bulbs, and stored in dry sand or earth till planting time comes again. Hyacinths especially deteriorate if left in the soil, and it may be laid down as a maxim that the more liberally the bulbs are treated after flowering, the more useful the bulbs will be for another season. Offsets, if carefully cultivated in a rich piece of light soil for two or three years will then produce a good many flowering bulbs, but, as a rule, imported bulbs are best; however carefully they may be cultivated in England, they seldom or never flower again so well as the first season, and so generally is this admitted that many throw the old bulbs away annually and procure new supplies. A good plan is to plant in the mixed border, when they often make a good show amongst herbaceous plants, or skirting the fronts of shrubberies. Selections for bedding in distinct colours of red, yellow, blue, white, or mixed, are to be bought at a cheap rate from any respectable seedsman or nurseryman, and a comparatively grand display may be made on a large scale with little outlay.

Godetias.—These are among the most beautiful of hardy annuals for spring flowering. They require to be sown now in order to secure strong plants before severe weather sets in, and if well thinned out and the soil be rich they will give a grand display of blossom during

Godetia rubicunda.

May and June, and if seed be sown again in April a succession of bloom may be easily kept up. As pot plants for window culture these Godetias are excellent. They require to be grown out-of-doors or in a cold frame till they show bloom, when they may be placed in a sunny window, where if kept well watered they will bloom for many weeks. The flowers should be clipped off as soon as they fade in order to

Godetia Whitneyi.

prolong the season of blooming. Among the best kinds are G. Whitneyi, G. Lady Albemarle, G. Lindleyana, G. The Bride, and G. rubicunda.

LILY CULTURE.

MANY of the common Lilies, such as the old White, the Tiger, the Orange, &c., will thrive in almost dry soil, and are not fastidious as regards situation, although they prefer a certain amount of shade and shelter. Even these free-growing kinds, however, give better results when some provision is made to meet their peculiar requirements. If the natural staple is very heavy and retentive, lighten it by the admixture of river-sand, leaf-mould, or anything of a like nature; if, on the contrary, light and parching, add thereto some sound loam, or good, free, rich soil of any kind, and mulch around them with short Grass or something of a like nature during the summer months. If the culture of such kinds as speciosum, auratum, Krameri, japonicum, or any of the more rare and beautiful kinds is to be attempted, then a thorough preparation of the soil must be made. There are but few kinds of Lilies that might not be grown with success in almost any part of England were their special likings more carefully considered. L. auratum and speciosum will thrive for a season or two almost anywhere, and will then, in nine cases out of ten, completely disappear. Why is this? Why, is often asked, do they flourish for a time and then die away? Simply because, being planted in unsuitable soil and in an ill-drained situation, the roots and bulbs perish through excess of humidity. Lilies do not like full exposure to the hot sun, and they never appear so much at home as when pushing up through dwarf evergreen or deciduous shrubs, where the greater portion of the stem and the roots are protected against its scorching rays. They also dislike rough or cutting winds, and rejoice in a cool, moist atmosphere during the summer months. Beds or borders occupied by Rhododendrons, Azaleas, &c., where the soil is pure peat, is found to be just the place where the Japanese species flourish best, and where they do not appear to wear out. Supposing, however, that such natural advantages do not exist, then we must choose a position in the shadiest and most sheltered part of the garden. Excavate the natural soil to a depth of 18 in., and should the situation lay low and damp, ensure good drainage by placing about 4 in. of brick rubble, or bushes, or anything likely to serve the purpose, at the bottom, filling up with good peat. This may appear to many to be too expensive, but almost everyone who owns a garden might carry out these details on a small scale, and the grower will certainly find that a dozen bulbs well planted will give greater pleasure than hundreds could do if the proper means are not taken to ensure their well-being.

Plant the bulbs some 6 in. deep in the soil, and allow them to remain undisturbed, and they will yearly increase in luxuriance and effectiveness. Some recommend a mixture of loam and peat for planting them in. This is undoubtedly the best compost for pot culture, but our winters being generally moist, it is imperative that the soil for outdoor culture should be of a free and porous nature, and that every facility should be afforded for surplus moisture draining away. I therefore counsel the exclusive employment of peat for the rarer kinds, and if it should be of a somewhat sandy nature so much the better; in any case, the addition of some coarse silver sand cannot but prove beneficial. Having planted the bulbs and marked the places, the next step is to plant some low-growing evergreens, which may carpet the soil, and thus preserve it cool and moist. Such things as Skimmia japonica and oblata, Pernettyas, Gaultheria procumbens, Daphne Cneorum, Menziesia polyfolia, Heaths of kinds, and Rhododendrons of the Alpine section, such as chamæcistus, hirsutum, and præcox, are all excellent for the purpose, and are exceedingly ornamental in themselves.

A portion of the garden thus arranged cannot fail to be a source of constant pleasure, as if planted with a variety of Lilies, a succession of bloom will be maintained throughout the summer months. For pot culture a good heap of compost should be prepared, consisting of loam, peat, and leaf-mould in equal proportions. There are some species which demand pure peat, but the beginner should limit himself to the more well-known kinds, of which the culture may be said to be well understood, such as auratum, speciosum and varieties, longiflorum and varieties, canadense, superbum, and Thunbergianum atro-sanguineum. Procure the bulbs in the autumn, and pot them either singly in 6-in. or three together in 8-in. pots. Give good drainage, water moderately, and plunge the pots quite to the rims in a cold frame, there to remain until they commence to grow, when air should be freely admitted. When all danger of frost is past, place them in a sheltered and cool position in the open air, watering freely when in full growth, and syringing the foliage in hot weather. When the blooms begin to expand remove them to an airy and cool greenhouse.

Byfleet. J. C.

A very Free-flowering Everlasting.—When ordering my flower seeds in spring I got among others a penny packet of Xeranthemum, which sowed about a square yard. It is now a dense mass about 2 ft. high, with hundreds of flower-buds on it. I have already gathered a great many, and many new ones are opening every day. The flowers are purple (dark and light) and yellow, double, semi-double, and single. I have also gathered a splendid crop of Rhodanthe maculata, and have as good a one of Helichrysum—some of it gathered, and most of

it nearly ready. All were sown in the open border.—PED.

Shrubby Gromwell (Lithospermum fruticosum).—This singularly beautiful little plant is a real gem on outside rockeries in spring and early summer, the intense blue of its flowers being quite equal to that of any of our alpine Gentians. It is a compact-growing, old-fashioned little plant, and the freedom with which it may be increased places it within the reach of everybody. It may be propagated either by means of division or by cuttings inserted in a warm border under a hand-light in summer, and shaded for a few days with a piece of mat or other material. The following is, however, the best and most certain mode of increasing it: A few of the plants should be lifted and potted early in autumn, so that they may have time to get well established before the winter, and have the protection of a cold frame after the middle of November. The sashes should, however, always either be drawn completely off, or tilted up on the side opposite to the direction from which the wind blows, unless the weather is too severe to permit of such being done. Towards the end of February these plants should be looked over, cleaned, top-dressed, and introduced into the propagating pit. This sudden change induces them to make young growths rapidly, which may be taken off and inserted as ordinary cuttings. They strike root readily, when they should be potted singly into 2½-in. pots and again plunged in bottom-heat, where they soon establish themselves, and after they make another 2 in. of growth, their points should be cut off for a similar purpose. A week or so after being deprived of their tops they should be lifted out of the plunging material, and, after being levelled, set for a day or two on the top of it; then they should be placed on a side shelf near the light. Unless it is necessary to obtain a large stock of this plant, it is not advisable to take more than one cutting off each cutting; but the old plants, from three weeks after they are brought in until a sufficient quantity of young plants has been obtained, will, if properly treated, continue to yield cuttings abundantly. No flowers should be permitted to develop themselves during the season of propagation, as their presence only hinders that work, as well as exhausts the plants. Thus treated, compact little plants may be had in about two months, and before planting them out they should be gradually but thoroughly hardened off; indeed, I do not think they can ever be safely trusted outside before May. Six or eight good plants started in this manner in February should, by the end of April, furnish at least three hundred good young plants.—W. F.

Cineraria maritima.—This, though an old inhabitant of our gardens, is not so often seen as it ought to be. The whole plant is of the purest silvery white, with the exception of the upper surfaces of the leaves, which are greenish, although in a degree covered with wool, and perhaps in the whole vegetable kingdom no leaf is more beautifully cut. It is of a shrubby habit and may be freely used in the outsides of choice masses of shrubs; those, too, who edge their masses of shrubs with some particular plant will find this a very striking plant, as it may be kept to any height that may be required, and a mass of this plant edged with some dark green dwarf shrub would be a sight, and, if properly attended to, would equal, if not excel, any of the Centaureas. It is a fine plant for toning down masses of blue or purple; a few plants might also be introduced with advantage into the conservatory. In short, from its peculiar whiteness, it is attractive in any place, and is a most charming window plant.—T. W. O.

Wintering Pelargoniums in Cellars.—Take up the plants, shake off the earth from the roots, trim off the longer ones, and head back the tops freely; then place as many of these trimmed plants in a box or small tub as can be crowded in without much pressure in the same position as they would stand when planted in pots. Then pour in among the roots as much dry clean sand as will compactly fill all the interstices, occasionally shaking it to settle the sand till the tub is nearly full; place them in a cellar where they can receive as much light as possible, and keep the sand slightly moist by occasional watering. In very damp cellars no watering will be required. The roughest boxes will do. The plants will require a little occasional attention during winter, to see if all is right, and that they are not suffering from any cause, which a little experience on the part of the attendant will enable him to ascertain.

Gilias.—These are hardy annuals growing from 1 ft. to 2 ft. high, and bearing for a long time in succession abundance of blue, white, lavender, or rose-coloured blossoms. The seed

Gilia laciniata.

may be sown in autumn for spring blooming, and in April for summer and autumn display. They should be grown in masses to be effective, and the soil should be light and well enriched

Gilia tricolor.

with decomposed horse or cow manure. The flowers are useful for small bouquets or vases, and last for a long time in water. The best kinds are G. achilleæfolia major (blue), G. a.

Gilia capitata.

alba (white), G. capitata (lavender), G. tricolor (white and purple), G. rosea splendens (rose), and G. nivalis (white). A mixed packet of seed will also give a fine variety of colours.

Wintering Half-hardy Bedding Plants.—Most kinds of half-hardy bedding plants are readily struck from cuttings inserted about this time (September), but they succeed much better if struck earlier, say the first week in August. All sections of the Pelargonium family, including the variegated and tricolor kinds, will root readily in pots or boxes filled with light, sandy soil and placed in the open air, or they may be inserted in the open border and taken up and potted about the beginning of October. In the absence of a greenhouse or glass structure they may be wintered in a light room as near the windows as possible, setting them back during severe frosty weather, and giving very little water during the dull days of winter. Frost should, of course, be excluded by fire-heat or otherwise, although 3° or 4° will not injure them. Verbenas, Calceolarias, &c., may be inserted in the form of cuttings in a mixture of sand and finely-sifted leaf-mould using well-drained pots some 6 in. in diameter, and these should be placed in a frame, which should be kept quite close until the cuttings are fairly rooted, when air may be freely admitted whenever the weather is fine. Such plants may generally be wintered in an ordinary garden frame, but care must be taken to cover the frame with mats or litter during very severe frosty weather, when water should be given very sparingly, and only when the soil is found to be dry. Those not in possession of glass structures should trust more to annual plants for furnishing their flower beds than they usually do. Annuals may generally be sown where they are intended to flower about the end of April or early in May, or, what is better, they may be sown in pans, pots, or boxes about the beginning of April, and placed in a frame on a slight bottom-heat, pricking the young plants out when large enough into other pots or pans, and gradually inuring them to the open air, finally planting them in their beds soon after the middle of May. Many annuals make excellent bedding plants. Nothing can surpass in beauty some of the varieties of Phlox Drummondi, Dianthus Heddewigi and its varieties, some of the dwarf Marigolds, Asters, Stocks, &c., all of which will remain in great beauty throughout the greater part of the season.—P.

THE SHRUBBERY.

A Fine Hedge.—The prettiest Quick-set hedge I ever saw was in Ireland, forming a boundary fence between some pleasure grounds and the public road. It was straight and impervious as a wall, and as thick and close at the bottom as at the top. When I saw it in winter it had quite a brilliant effect; being made of Beech or Hornbeam, with Hollies at intervals of 12 ft. or more, it was much less monotonous and warmer to the eye than Evergreens alone would have been, the bright warm brown of the Beech contrasting finely with the shining green of the Holly. This fine hedge must have been very old, being about 7 ft. high, and it extended for a considerable distance, doing much credit to the Irish workmen, who had inarched the young branches well from the beginning.—H.

Sowing Broom Seed.—Most kinds of Broom, but more especially those of the largest growth, known as Portugal Broom, flower early in May, and ripen their seeds by September; and the sooner these seeds are committed to the ground after they have been gathered, the better plants will they make the following summer. They may, however, be sown with Gorse in the spring, or transplanted among it as seedlings. It is difficult to say in what proportion these seeds should be sown together for ornamental purposes, but we would recommend a trial of 1 lb. of Broom to 3 lb. of Gorse.—A. J. B.

Garrya elliptica is a dark-foliaged, handsome evergreen, of free, quick growth after the first two years, or when well established. It should be planted in good well-prepared soil, and will then speedily cover an unsightly wall. Its long catkin-like inflorescence is at this season both singular and interesting.

Eucalyptus globulus as a Disinfectant.—It seems to me a fact worthy of recording that, having planted about a fortnight ago a small plant of the above, 4 ft. high, close to a cesspool, so that the roots might gain some nourishment from it, and sheltered by some Fir trees, all offensive smell, even in this hot weather, has disappeared. I mean to give this plant a trial as to whether it will stand the winter here (the east coast of Scotland).—H. K.

Garden Ornaments.—I made a handy little table for my garden in the following manner: I obtained from a cheesemonger the lid of a cheese box, round the edge of which I nailed pieces of the hoops (purchased at the cooper) 3 in. long, pointed at the ends. For the stand or pedestal I used broom-handles nd Dahlia sticks, and with the exception of

the rustic edging I painted it green, and then varnished the whole. The table is very firm, and will stand any amount of knocking about without injury. A very pretty and useful little box (rustic) for in or out-of-doors I made as follows: For the foundation I got an empty blacking box 13 in. long, 5 in. deep, and 7 in. wide; I then cut pieces of the old hoop (previously alluded to) into lengths of 7 in. and painted them top and bottom; I then fixed them on with French nails clenched inside. I made plenty of holes in the bottom for drainage. The stand, in form of a tripod, I made of thick pea-sticks with two pieces running the whole length of the box, so that the pressure on the stand should be equal. The stand itself I ornamented with pieces of cork; I then varnished the whole once or twice, and very well it looks. Last winter I had it full of Ferns in the sitting-room, and this summer I have in it Lobelias and a fine crimson Geranium.—A. H. B.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

September 27.—Potting Double White Feverfew from borders; also a quantity of Selaginella in 3-in. pots for room decoration; potting up Pinks on account of wireworm. Putting first batch of Roman Hyacinths and Roman Narcissus to force in very slight heat; putting Myrtles and Orange trees into conservatory; also Heliotropes in pits for winter flowering; taking up and potting Hollyhocks, and placing them in a cold pit; pricking out Cauliflowers, also Red and Green Cabbage, and more Lettuce; nailing in Peach trees a little; syringing Peach trees with soap-suds and Tobacco-water for green-fly; also Azaleas for thrips, using 4 oz. of soft soap to a can of water; cutting Marjoram, tying it in bundles and putting them in a Vinery to dry; roping some Onions to put in loft for keeping; getting up Carrots and Beet-root.

Sept. 28.—Potting Japan Lilies; also Solomon's Seal for forcing; getting scented leaved Pelargoniums into pits; putting in cuttings of Viola cornuta in cold frame; pricking out Cauliflowers under the protection of a south wall; putting cases over French Beans in the open border; gathering Winter Nélis, Winter Bon Chrétien, Gansel's Bergamot, Brown Beurré, and Thompson's Pears.

Sept. 29.—Potting Pelargoniums, consisting of old plants of Mrs. Pollock, Goldfinch, Cloth of Gold, and Golden Chain, from flower beds; putting Primulas into lean-to pits, keeping them at from 55° to 60° at night; putting Eucharis into Cucumber pit for winter flowers; gathering Marie Louise, Napoleon, Beurré Superfin, Jersey Gratioli, Zephirin Grégoire, Beurré Diel, Crassane, Colmar, Beurré d'Aremberg, and Louise Bonne of Jersey Pears; also Golden Pippin and Broadling Apples; getting up all root crops; getting Onions under cover; making a frame ready for Calceolaria cuttings; spreading manure on land for spring Cabbages; earthing up winter Cucumber plants.

Sept. 30.—Sowing Cucumbers for planting in January; taking up some seedling Lobelias and putting them in well-drained boxes; getting all Mignonette, Salvias, and Pelargoniums under cover; taking up Cauliflowers and putting them into a cool place to keep; planting Maréchal Niel Roses in greenhouse, also a large quarter of Cabbage out-of-doors for spring use; gathered all fruit except Easter Beurré Pears and Nonpareil Apples; putting some fresh soil to Peach trees; putting lights on Peach-house and Vinery, not shutting them up, however, except in bad weather; keeping Cucumbers at night about 70°, and Mushroom-shed about 55°.

October 1.—Potting Magnolias, also late Tulips and Anemones, and plunging them; getting Callas under cover, also Carnations into pits for winter flowering; housing all greenhouse plants which had been placed out-of-doors for a time; putting Achimenes beside pipes in stove; re-arranging Orchid-houses; planting last year's forced bulbs to bloom in spring; pricking off four lights of Cauliflower plants in frames; gathering Peas sown July 10.

Oct. 2.—Cleaning June-struck Heliotropes and putting them in greenhouse; laying in a large quantity of Cerastium; clearing scale off Peach trees; putting rough frame together for the protection of half-hardy plants; beginning to make turf pit; cleaning autumn-sown Onions; pulling up and burning all vegetables in garden as they get useless.

Glasshouses.

Double Primulas.—These are not nearly so much grown as the single varieties, which, to some extent, may be accounted for by their much less showy character and liability to damp off unless somewhat differently treated from the single kinds, but where the flowers are needed for cutting, the advantages are very much in favour of the double ones, as they do not drop nearly so quick. Where a little more warmth can be given them all through the winter, little difficulty will be found with them. Nothing answers so well as a small pit or house where they can be kept to themselves, or in company with Cyclamens that are wanted to flower early, kept near the light with a moderate admission of air on fine days and a night temperature of from 45° to 50°; damp will not give much trouble, and the plants will keep on thriving, making double the progress possible in ordinary greenhouse warmth. Such persistent flowerers are they that the smallest examples keep on blooming, but where the plants are not wanted until later on, the flowers should be picked out as soon as formed, which will much accelerate their attaining size. Weak manure water will be found of great use to them.

Lilies.—As these die down whatever potting or renewal of the surface soil is required will be much better carried out now than later on, as when they are put in out-of-the-way places where many are compelled to accommodate them, the re-potting and consequent disturbance of the roots get deferred until fibres are being made, when much injury is done. All the kinds that form young bulbs on the lower part of the flower-stem that is under the soil, but above the principal bulbs, should be gone over now with a view to remove these, whether the main roots require potting or not, as if the young bulbs are allowed to remain, the pots in a single season get so crowded that the soil is not capable of sustaining the flowering bulbs in the way they require. Strong loam with a little admixture of leaf-mould, rotten manure, and sand will grow all the strong-growing kinds stouter, and so to enable them to produce a greater number of flowers than peat, and also to induce them to increase faster. The weaker-rooting, less free-growing kinds peat seems to suit best. Attention as to re-potting soon after the tops have decayed is particularly advisable in the case of bulbs that have only this summer made their first growth after being imported. These, especially L. auratum, frequently make growth and sometimes even produce a flower or two, at the same time forming little or no roots. Bulbs of this description very seldom live beyond the first season, and they are usually such as have begun to push roots after arriving in this country previous to being potted, and the young tender fibres being injured before or at the time of potting died right back, when through inability in the bulbs to push more roots there was nothing to support them, the shoot growth they made generally being the exhaustive and last efforts the plants were able to make. All who purchase imported Lilies, and this species in particular, should get some, and as soon as the first importations arrive pot them at once, as these generally give the most satisfactory results. Another matter we would impress upon young cultivators is the absolute necessity for using small pots; even in the case of established plants, that is, those which have been grown in the country some time, it frequently happens that they are over-potted.

Scented-leaved Pelargoniums.—Many of the winter-flowering plants, forced or otherwise and required for cutting, are weak in perfume, and a handsome-looking bouquet is all but scentless. This is easily remedied where a sufficient quantity of the sweet-leaved Pelargoniums are grown to meet the requirements of the very different tastes in this matter, from the rose-perfumed P. graveolens and the varieties of P. capitatum to the ordinary citron and lemon-scented kinds; these, if well managed, so as to get stout healthy growth in them with ample clean foliage that has never been allowed to get infested with aphides, and if kept under glass early in the season and then turned out in the open air during the latter part of summer, will get their leaves hardened enough to keep fresh in a cut state for some days, but though so easily grown they need sufficient attention to have them in the best condition.

Callas.—Where these are grown on the system of division in the spring, and planting in the open ground with a view to their being potted up in the autumn, they should at once be lifted and placed in the pots in which they are to bloom; these need not be larger than will just admit their roots and a moderate amount of soil without too much cramping, as when they have flowered through the winter and spring they will again be turned out-of-doors as before. They are water-loving plants, and will bear the soil well moistening immediately they are potted; grown in this way their leaves are very stout, and the petioles consequently are much less likely to be broken, and their handsome foliage, when perfect, adds so much to their appearance when in bloom, that it is worth a little extra labour to keep it whole. A single stick to each pot, so as to just support the leaves, will be found sufficient to ensure this. The plants when potted may be placed close in any house or pit available, where they can remain till the roots have got established, and after a time be placed in the greenhouse to bring them into flower as required.

Flower Garden.

Bedding Plants.—In cases in which it may have been difficult, or even impossible, to obtain at an earlier period a sufficiency of cuttings of any variety of bedding plants, this deficiency may now be made good, and the propagation of all such plants should be brought to a close as speedily as possible. Even bedding Calceolarias, which are always found to succeed best when the cuttings are inserted somewhat late, may soon, or even now, be commenced with. These plants are most successfully propagated in cold pits or frames, either in pots or otherwise. If pots are used they may be some 8 in. in diameter, and should be well drained, and the soil may be composed of one-half leaf-mould finely sifted, while the other half may be sharp river or pit sand, which will answer the purpose quite as well as the best silver sand. They may be wintered in the pits or frames in which they have been struck, and will of course require the protection of mats, &c., when the weather is severe. Treated thus, they will generally be found by the end of March to be in good order for transplanting into temporary pits or trenches, where they can have the necessary protection which they may require during very severe weather; from such quarters they may be transferred to the flower beds in May.

Carnations and Picotees.—Arrangements must now be made to remove all layers and pot them either singly in 3-in. pots or a pair of plants in pots of a larger size. The compost that seems to answer best is four parts good sweet maiden loam, one part leaf-mould, and one part sharp sand. When the plants are potted place them at once in a cold frame, water with a fine-rosed watering-pot, and then place the lights over them, keeping them rather close and shaded for a week until they have formed fresh roots.

Dahlias.—The blooms should still be thinned out, and the stems should be tied to the sticks as they advance in growth, as the plants are very heavy and easily injured by winds. Shade the flowers, especially the light-coloured and pink ones, and see that the ground is kept stirred with the hoe.

Gladioli.—The ground between the rows should be well stirred with a hoe, or if it is wet, the surface may be lightly forked over, in order that there may be a good opportunity for the bulbs to ripen. It is not likely that they can ripen well when the soil is trodden hard between the rows, the surface quite wet, and in places covered with a growth of green Confervæ.

Pinks.—If pipings of these have done well, now is the right time to prepare a bed in which to plant them. When a Pink is lifted out of the ground it does not seem as if the roots run far from the main stem, but they do. They run well into the ground, and it is best to trench the beds 2 ft. deep, working into them some good rotted stable manure, some of it at the bottom of the trench, and some of it 6 in. under the surface.

Tulips.—If the ground intended for these has been cleared from other plants the beds may be prepared at once. Growers who make a speciality of them take infinite pains to prepare the beds well, excavating the soil to a considerable depth, and then filling the space with good loam mixed with rotten manure. Those who cannot afford this would do well to trench the ground to a considerable depth and manure it well; then at planting time they should place about 6 in. of rotten, chopped-up turfy loam on the surface, and in that plant the bulbs with a little sand under and over them.

Fruit.

Apples and Pears.—Most kinds of these will soon be ready to gather, and the moment they seem ripe enough let it be done, as we may soon expect high winds, and ungathered ripe fruit will be either destroyed or fit for use only as windfalls. Pears, especially late kinds, if gathered too soon are rendered worthless, as they never ripen either to be fit for cooking or

dessert, but shrivel and become hard and dry. A good criterion by which to decide whether a Pear is fit to gather or not is to gently raise the fruit, and if it parts readily from the tree, it is fit to gather. Another plan is to cut open a fruit, and if the pips be brown, the crop may be gathered. The same rule applies to Apples, though none but the very late kinds suffer from early gathering to the same extent as Pears. After housing the fruit the room will require to be freely ventilated for a week or two until the fruit is dry and inured to the temperature of the house; sudden fluctuations more than anything else induce damp and decay. Fruit showing the slightest signs of decay should be instantly removed, for if left an atmosphere is thereby engendered inimical to the good keeping of the remainder. If space permit let the fruit be placed on the shelves in single layers; any extra labour involved in so placing it will be more than repaid by the despatch with which it can be examined in order to detect bad fruit.

Peaches and Nectarines, and also late Plums, should be gathered a day or two before they are fully ripe, and placed in the fruit room. Fruit so gathered is much more highly flavoured than when used direct from the trees. As soon as the latter are cleared of fruit wash well any that are affected with red spider or mildew. Plenty of clear water applied with force for the former, and soapsuds for the latter, are two simple and effectual remedies.

Raspberries may now have all their old fruiting canes removed and the new ones finally thinned out in order that those for next season's fruiting may derive the fullest benefit from what sunshine we may yet be favoured with. After thinning let the ground about them be "pointed" (not dug deeply), then mulch thickly with well-decayed stable manure. The fruit tree planting season is at hand, and preparation should therefore be made for new plantations, and for lifting, root-pruning, and renovating any trees requiring such operations.

Vegetables.

The general crop of Celery for winter use should now be examined; all suckers should be removed, as well as a few of the smallest outside leaves, and then the foliage should be tied together loosely; after that a thorough soaking with manure water should be given, and then about 6 in. of soil from the ridges should be drawn to the plants, an operation which not only keeps the leaves from being broken down by wind, but tends to promote growth, and where too much soil is not applied, it has no bad effects in preventing rain from reaching the roots. The Celery maggot is now in some places active; it may easily be detected by the brown patches which it produces on the leaves. The only remedy is crushing it between the thumb and fingers. The Cabbage caterpillar is also now attacking late Cauliflowers. They get into their hearts as soon as they begin to form, and for these no dressing can be applied that would not spoil the heads; consequently hand-picking must be resorted to, otherwise the larvæ will continue their work of destruction until the occurrence of sharp frost.

House and Window Gardening.

Spleenwort as a Room Plant.—The common Spleenwort, sometimes called English Maiden-hair, is one of the prettiest Ferns that can be grown for indoor decoration. In its wild state it is a favourite and pretty Fern, but its wiry stalk is so brittle, that even in a sheltered Devonshire lane the fronds are seldom perfect, and generally disfigured by what look like a number of black pins stuck among them. When grown under a bell-glass it is a different plant. I have seen the fronds 12 in. in length with perfect rows of vivid green pinnæ arrayed on the shining black stems, and making beautiful luxuriant plants grown in a bedroom with a northern aspect, and where a fire is never lighted. Though the Adiantum trichomanes is known as the common Spleenwort, it is not really very abundant, and I would beg of those who may wish to carry some of it away from its native haunts not to be spoilers, but to take tenderly only what can be spared and what they can use. But this much I would say for the very commonest Fern in England.—H.

Dwarf Hyacinths in Sand.—I get dwarf Hyacinths from Holland in five different colours; they must be of the sort which "feather"—those growing with an upright stem are not fitted for the purpose. I take five deep dishes—say pie dishes or China dishes—putting about ½ in. of fine sand at the bottom of the dish, one of the bulbs in the centre, and seven round it; I cover the whole with sand, merely up to the crown, damp it well, and put it in the dark, in the same manner as other bulbs in pots. They must be looked at occasionally, and must be kept damp. When they are found to be about 2 in. above the sand they should be brought into the light; and when about 1 in. higher the sand should be taken off the top, and be replaced by fresh, short Moss. They are then in order for blooming, and are an exceedingly pretty ornament for a table. It is essential that the eight bulbs in each dish should be of the same colour; I generally have them of white, pink, dark blue, red, and yellow. I am aware that this is by no means a new way of growing dwarf Hyacinths, but it is one which I have never seen adopted in England. It is very effective if they be carefully treated.—W. B.

Duration of Passion-flowers in a Cut State.—I cut on July the 29th last from our greenhouse two long branches of the Blue Passion-flower plant. The leaves of both remained quite fresh and green for more than a month in water, and now (September 4) more than half of one graceful spray is fresh and green. They had plenty of water and were long branches. I think this useful to know. Can any reader give similar instances?—C. D. E.

GLASSHOUSES & FRAMES.

Hoya bella.—The Hoya has been mentioned lately in GARDENING, and it may interest some of your readers to learn that there is now a Hoya bella in full beauty in a cool greenhouse in the south of Devon. It was raised nine or ten years ago from a small cutting in silver sand under a wineglass. Four years ago, being unable to attend to it, I sent it to a friend who had all the appliances for growing stove plants. It was then a sturdy little bush, and had flowered beautifully two or three years. Last April it was returned to me, the foliage showing the effects of artificial heat. There were many flower-buds formed on it, but the change seems to have checked it, and the buds for the most part withered and dropped off. As the season advanced it began to shoot vigorously, and covered itself with fresh green foliage crowded with flowers. It is now a bush measuring about 2 ft. 6 in. every way, and I think it will be under rather than over the mark to set down the number of clusters at 300. My friend's gardener trained the branches to hang down, and must have managed the plant very well; still, I think it would have prospered in my cold greenhouse (a lean-to at the back of the drawing-room chimney), and there would probably, too, have been the convenience of less rapid growth, for it now takes more room than I can well afford it.—M. M.

Gladioli for Late Flowering.—Bulbs of these that were kept long out of the ground in spring, with a view of their being potted for flowering in the greenhouse in autumn, should this month be taken up and potted. If the ground be at all dry give them a good watering previous to their being got up, otherwise the roots are certain to get broken. Do not use larger pots than will hold the roots without undue pressure, say 6 in. or 7 in. in diameter. Any ordinary garden soil will do for them. The usual advice, not to give water for some days after potting, must not be adhered to in the case of these and anything of a similar character, otherwise the foliage would be certain to suffer. As soon as they are potted give as much water as will moisten the soil, and put to each a neat stake to support it; place them in a cold frame or Vinery, or wherever room can be found where there is no fire-heat. Thus treated, they will come into flower in succession for some weeks, and are very useful for greenhouse or room decoration. Expensive sorts are unnecessary, but such should be selected as naturally flower late.

Propagating India-rubber Plants.—I find cuttings of the India-rubber plant (Ficus elastica) root best in spring. Any light, sandy soil will answer the purpose, and a bottom-heat of from 70° to 80° greatly facilitates the process of rooting. Side branches or tops, 6 in. or 8 in. long, root equally well. Some cut the branches to single eyes, leaving a leaf to each, and these root readily on a gentle bottom-heat in a moist atmosphere.—H. B.

Greenhouse and Conservatory Climbers.—Such of these as flower in the summer and admit of their being cut in at this season possess an advantage deserving of consideration in making a selection of plants for the purpose, for during the bright summer months where not allowed to cover the roof too closely, they, to some extent, supply the place of ordinary shading to keep the general occupants of the house, when in flower, from being too much exposed to the sun. Those that thus bloom during the summer months, and will bear cutting in more or less yearly, should now have their shoots shortened, an operation necessary to admit as much light as possible to the other occupants of the house through the winter. Amongst them will be found the summer-flowering Bignonias, Hoveas, Hardenbergias, Kennedyas, Passifloras, Tacsonias, Plumbago capensis, &c. The beautiful sweet-scented Mandevilla suaveolens, although a plant very subject to red spider, is well worthy of all the attention necessary to keep it clear from this pest, for when it has attained a considerable size it will continue for many weeks through the autumn, producing a succession of its white trumpet-shaped flowers. Swainsonas, Habrothamnus elegans, Jasminums, Clianthus puniceus, Chorozemas, and Acacias are also all good. It is not desirable at this season to cut more away than is absolutely necessary, as whatever branches are removed will tend to lessen the quantity of flower they are likely to produce in the spring, but where these have grown too large for the situation they occupy either trained on pillars or on the roof they should be judiciously thinned out; so treated they are much better both in appearance and reality than where an attempt is made to tie them in so close as to make them look stiff and formal. All plants of the above character should, where they require it, now have a thorough clearing from insects, as from their position overhanging other plants they are certain to communicate whatever they may be affected with to the plants standing beneath them. Should any happen to be infested with that worst of all pests, white scale, the most effectual method of dealing with it is to cut them in so far as to admit of their being taken down from the wires that support them, and have the whole of their heads immersed in liquid insecticide sufficiently strong to kill the insect; the application of any liquid by sponge or brush, however effectual it may be for the destruction of this species of scale, can scarcely ever be used so as to completely eradicate it, from the difficulty of so getting the dressing to reach every part infected, whereas if dipped overhead the entire surface of the plant is reached. This insect is so hard to kill, that even when the plants are close cut in, so as to leave nothing but the hard wood, it often takes several applications before all are destroyed. Now when growth has ceased, by beginning early and repeating the dressing through the winter, affected plants may be cleaned.—B. A.

Cut Flowers and Packing them.—Having had much experience of the above, and seeing advice asked in GARDENING ILLUSTRATED respecting it, I beg to offer a few remarks. Of Roses, some kinds are useless for vases; having over 100 sorts, I can speak to the following being always good, by which I mean lasting from two to ten days, according to texture: Safrano, Madame Willermoz, Niphetos, Céline Forestier, Gloire de Dijon (gathered half or full-blown buds of this I find will not open in water), Fisher Holmes, Marshal Vaillant, Lord Raglan, John Hopper, Paul Neron, Charles Lefebvre, François Fontaine, Maurice Bernardin, Souvenir de la Reine d'Angleterre, and Gloire de Sautenay. All these will last well, and some improve in water, but care must be taken that no portion of the old wood is cut. As to the implement, I find that a matter of perfect indifference; I use my nails as often as scissors or knives; Selby's flower-gatherer is undoubtedly the most convenient article. Having about seven-

teen flower-vases about my rooms, I cannot, of course, be at the trouble of cutting the stems daily. My plan is to fill up all that want water every day, to pick out all decayed flowers, and in winter cut the stalks about once a week. Geraniums, Mignonette, and Phlox Drummondi, gathered in November, have often lasted into the new year treated thus. I do not have gas, and never allow the vases to remain near the lamp in winter. Now as to packing: I gather the flowers half-an-hour beforehand and put them immediately into a basin of water; if there are any very choice ones, I get some wool or morsels of sponge soaked in water, and secure round the bottom of the stems with a scrap of oiled silk or waterproof cloth. The despised draper's boxes are the only ones I ever use, except for cuttings, as the tin cases are so heavy; but the simple precaution of writing the address on a luggage label, so fastened to the box that the stamps can be put in the P.O. marker without the box, suffices to prevent all smashing.—J. B. T.

Habrothamnus elegans argenteus.—This is one of the most beautifully variegated of greenhouse plants, and one that may be grown for covering a wall or pillar. In the latter situation it is especially ornamental; the leaves, as will be seen by the annexed illustration, are about 6 in. in length by 1 in. in breadth; nearly the whole of the surface is soft creamy-white, beautifully tinged with rose, and relieved by irregular blotches of pale green; the flowers are produced in dense racemes, tubular, about 1 in. in length, and deep reddish-purple in colour, affording a striking contrast to the delicate white of the foliage. It is not so rampant a grower as the well-known H. elegans, and consequently it may be used for covering small columns or pillars, where the green-leaved kind would not be suitable. It has been grown in Mr. Williams' nursery at Holloway for several years past, so that it is now probably easily obtained. Any good, rich, sandy soil will suit these plants, and the oftener the flowers are cut off the longer will the plants continue to make new growth and bloom.

ANSWERS TO QUERIES.

2890.—**Plants for Shady Situation.**—Ferns (hardy) of all kinds, Myosotis dissitiflora, flowering bulbs, such as Daffodils, Snowdrops, Crocuses, &c., hardy Cyclamen, Saxifrages, such as crassifolia, Andrewsi, sarmentosa, and umbrosa, the common Columbine, the Gentianella (Gentiana pneumonanthe), Ramondia pyrenaica, and the whole family of Primrose and Polyanthus, including the beautiful P. cortusoides amœna, P. denticulata, and P. capitata. The Christmas Rose would also be likely to do well, and the small-leaved variegated Ivy thrives admirably in such a situation.—J. C.

2748.—**Furnishing a Plant Case.**—The dimensions of the case will have to be regulated by the amount of space at the disposal of the grower. It may be from 1 ft. to 2 ft. in height and of any desired length. One side of the case should be made to open, so that its contents may be easily examined, and to admit of giving a change of air now and then. The bottom of the case is to be of zinc, thickly pierced with holes, so as to admit of perfect drainage, the surplus water discharging itself into a shallow tray of zinc, so arranged that it may be drawn out easily, independent of the case itself, thus providing a means for emptying away surplus moisture. That portion of the case containing the soil will, of course, have to be of zinc, the depth of the same to be about 6 in. The bottom should be covered with crocks or pieces of brick, the compost to consist of turfy peat, adding to it some silver sand and a little crushed charcoal. I should also mention that in the top of the case it is advisable to fix a small ventilator, so that the atmospherical conditions may be better regulated. We do not see that there can be any objection to Ferns; some of them are amongst the choicest and most beautiful subjects for the purpose, and they thrive better than most plants in such circumstances. No plant case should be without one or more of the Filmy Ferns, such as Todea superba, T. pellucida, and the Killarney Fern. The confined atmosphere of a case just suits them, and with care they last in beauty for years, and when in good health they are surpassingly beautiful. Then there are the Mosses, so charmingly fresh and verdant, such as the neat-habited Selaginella apoda, the elegant S. circinalis, and the climbing species cæsia arborea, the metallic hue of which renders it at once distinct and beautiful. Cyperus alternifolius variegatus is a pretty plant, and Fittonia argyroneura is a pretty variegated little plant, very distinct and attractive. There is also the Venus' Fly-trap and the little Pitcher-plant (Cephalotus follicularis), both interesting and manageable. Other suitable subjects consist of Sonerila margaritacea, Eranthemum sanguineum, Vriesia psittacina, Tradescantia zebrina, and the Artillery Plant (Pilea mucosa).—J. C., *Byfleet*.

2877.—**Improving Clayey Soils.**—If "A. O. A." will get road sweepings well mixed with horse droppings and throw on the ground pretty thickly, and let it remain for a month, or until the rain has carried the mixture well amongst the clay, then fork the whole over, well mixing as he goes along, he will find his land much lighter. If plenty of leaves can be spread over and forked in at the time, that will still further lighten his soil, and act beneficially as well. The above is the mode I adopted with a piece of very stiff clay for two or three years, and now it is friable and yields good crops.—R. B.

2897.—**Saxifrages Dying off.**—We know that some Saxifrages, especially those of the mossy section, are liable to go off in the manner described, but have always thought that the main cause thereof lay in the soil. Is yours of a retentive nature? if so, replace it with very sandy mould. We would advise that any plant showing signs of decay be at once taken up, cutting away all decayed parts, and pulling the plants to pieces, and dibbling them in freshly prepared beds. This will give them a renewal of life, and will in all probability stop decay.—C. B.

2830.—**Greenhouse Carnations and Pinks.**—It is very easy to grow any of the Carnation family in a greenhouse if layers be made now, and the newly rooted plants lifted and potted in November. These will soon get established and make strong plants, but it must be understood that unless they belong to the tree or winter flowering section they will not flower in the winter. To obtain these you had better apply to some good florist who is an extensive grower of these kinds, and will supply them well established in pots at about 18s. per dozen. There are about 50 kinds in commerce of all colours and markings. To name a few only would be useless, because these might be the most costly, though perhaps the best, but an order for a dozen plants of various colours would be the best method of securing a variety, and no doubt a good selection.

2835.—**Sowing Flower Seeds.**—If Carnation seed were sown at once plants might be induced to flower next summer, but it is uncertain, as properly the seed should be sown in April or May. Calceolaria seed may be sown at once, as also may be Lobelia, Pyrethrum Golden Feather, and Pelargonium, but this latter would no doubt be best if left till the spring, and then be sown in a gentle warmth. Even if the seed were now to germinate it might be difficult to preserve the seedling plants during the winter. Cockscombs are only tender annuals, and the seed must be sown in heat in the spring. The soil used should be one half sweet turfy loam, and the other half composed of either leaf soil or well rotted manure and sharp silver sand all finely sifted.—A. D

2990.—**Botanical Drying Paper.**—I purchased mine in a large paper warehouse in Edinburgh (Messrs. Cameron, Blair Street). The same kind is sold in Glasgow, but I am totally unacquainted with England, neither can I say at present if the paper is the same as that used in letter copying books. However, I will send a sample of what I have to "Novice," or any other one who may wish it, if they will send me their address. It is prepared specially for the purpose, and I believe is about the best. As to preserving the colours of flowers, every one who has tried it knows there are many flowers whose colours will not keep when dried, and in many cases the whole plant (flowers, leaves, and stem) turns quite black. But as far as the thing can be done I think I have been fairly successful, reds, yellows, blues, whites, &c., being still wonderfully good after being in my herbarium for years.—PED ARCHIBALD, *Kilmalcolm, Greenock, N.B.*

2913.—**Wintering Cuttings and Ferns.**—Such a frame as you state can be used for cuttings of Geraniums, Fuchsias, and other half-hardy plants. Make a bed inside of cinder ashes 4 in. to 5 in. deep; into this plunge your cuttings, &c. Let the ashes come nearly to the top of the pots. The principal thing is to avoid the cold from the outside; therefore, put plenty of cinder ashes all round the frame, and during frosty weather cover over the lights with bast mats, two or three mats according to the weather. Be careful not to water your plants too often during frosty weather.—JOE MILLER.

2834.—**Garden Refuse.**—"Amateur" will find muriate of lime to answer his purpose. Obtain some fresh burnt lime; to every bushel take about 6 lb. of coarse rough salt, and dissolve in a couple of buckets of water. Make the lime into a heap, and throw the salt water over gradually. In a short time the lime will break and fall into a powder. Prepare the vegetable refuse by making a layer 6 in. or 9 in. deep, treading it down well. Then spread a layer of the muriate of lime on that about ½ in. thick, then another layer of refuse, and so on until a depth of 4 ft. or 5 ft. is gained; then cover in with soil, or, better still, with Grass turves or sods, the Grass side downwards, and allow the heap to remain undisturbed until next spring.—SAXON DEYNE.

2989.—**Plants for Frames in Winter.**—Sowings of Lettuces and Cauliflowers to stand the winter might well prove the most profitable way to utilise an empty frame now, or else planted with strong roots of any kinds of Violets. It would be useless to plant or sow anything that required heat, or was too tender to withstand frost. As to a frame in which to preserve cuttings for the winter, a little warmth may be useful just now to assist in striking the cuttings, but the warmth will soon subside and be of no avail. Unless there is some other means of heating the frame, the tender plants could only be kept alive by excluding frost by the use of thick coverings and linings of long stable manure or straw. A concrete bottom may do if there is proper inside drainage, and it would keep down the moisture that will come up in the winter. The great things to do are—permit plenty of air, keep the plants and atmosphere dry, and exclude frost.—A. D.

3001.—**Carnations and Picotees.**—Unless you get plants of the winter-blooming or tree Carnations you can hardly hope to have Carnations and Picotees of the ordinary kinds in bloom in the spring, even under glass. July is the usual month of flowering, and it would need considerable forcing to induce plants to bloom so long before the customary period. Both Carnations and Picotees may be struck from cuttings, but the safest and surest way is to layer the side shoots in the soil where the plants grow, and when they are well rooted lift and pot them. Good turfy loam, with one-third mixture of well-decayed manure and sharp sand makes a good compost for these plants. A cold frame is the best place to winter them in, or else a shelf in a greenhouse where there is plenty of light and air. Yellow kinds, so-called, are merely French white kinds shaded with yellow, and may be had of almost any nurseryman who trades in plants of this kind. All the yellow ground kinds are more tender and difficult to grow than are the other coloured varieties.

2981.—**Hydrangeas not Flowering.**—Does not the lack of bloom on your Hydrangeas of which you complain result from the practice of cutting all the wood back each year? You say, "The plants are of course cut back every year after flowering." Why "of course?" If the severe weather cuts the wood back, there is no help for it; but to cut it back without reason is to invite failure. If the winters are severe then mat the plants over, and thus try to save the wood; but that can hardly be the case in the Isle of Wight. Thin out now all weak shoots such as would not perhaps produce bloom, and let those that remain have every possible chance to get well ripened; then, when the winter sets in and you do not fear frost, let all remain, and then see what will be the result next year; and we think you will be able to make a good report.—A. D.

2992.—**Hardy Edging Plants.**—Cerastium arvense, Herniaria glabra, and Veronica repens, all dwarf-growing dense creeping plants, make excellent permanent edgings for beds needing only occasional trimming. In the same way the hardy Sedum glaucum, lydium, and acre aureum are very useful and enduring. The first-named is silvery, the second green, and the third green in the summer, but charmingly tipped with creamy-yellow in the winter and spring. Of other plants, the common Thrift, the hardy wire Grasses (Festuca glauca and viridis), also the large woolly-leaved Stachys lanata, make good edgings and give a pleasing variety. The latter plants are most suitable for large beds.—A. D.

3000. — **Gloxinia crassifolia.** — Admit plenty of air and light to the plants from this time forward, watering when needful, but somewhat sparingly until the foliage shows signs of decay, when water must be gradually withheld. As soon as the leaves have turned yellow, turn the bulbs out of the pots and store them away in Cocoa-nut fibre or sand in a warm place until March or April, when they are to be potted in small pots in a compost of two-thirds peat and one-third leaf-mould, adding thereto some silver sand. Water very carefully, and keep them in a temperature of 55°. When they start into growth shade from hot sun, and as soon as they are seen to need it shift them into 4½-in. pots. Place them in a light position, give air on favourable opportunities, but avoid chilling draughts, and in hot weather maintain atmospherical moisture by means of frequent syringings and damping down the paths and stages. When the flower-buds appear remove to a cool greenhouse.—J. C. B.

3002.—**Ageratums not Flowering in the Usual Way.**—From the fact that your Ageratums assume such a squat, bushy habit it is evident that you have a variety known as Tom Thumb, which is more noted for this sort of growth than for blooming. The most free-blooming and beautiful kind we have seen is Cupid. It is this year in beds a perfect mass of bloom, and not more than 12 in. high. Countess of Stair is also a good kind. Both can be had in plenty through any florist no doubt, as these things may be propagated like weeds in heat. Whilst there are many objections to masses of brilliant colours in flower-beds because their frequent reduplication becomes tawdry and unnatural, this objection can hardly apply to the Ageratum, as its tint is soft and very beautiful.—A. D.

2979.—**Moles in Gardens.**—Moles are difficult to trap at this time of the year, because, owing to the surface of the soil being so dry the worms and grubs go deep and the moles work deep to find them. When the runs are near the surface it is easy to catch them alive by watching for the moment when the soil is seen to heave; then with a fork quickly lift the little animal from its run, and it may be either killed or caught. Where the runs are so deep that spring-traps are of no avail it is a good plan to saturate some rags tied to a twig in paraffin, and having set it on fire thrust it a little way into the run, so that the smoke and fumes may reach the holes. This is termed stinking them away, and is sometimes successful.

2987.—**Russian Violets.**—We should say that no course could be more destructive to Violets than the lifting and starving the plants in the autumn. We have had a grand season for Violets; plenty of moisture during the growing period and plenty of warmth and sunshine at the end of the summer to ripen the flowering crowns, and wherever the plants have been properly grown they will certainly carry an abundance of bloom next year. In the Middlesex market gardens, where Violets are grown in great quantities, the old plants are pulled to pieces in April and dibbled out again 18 in. apart. These make fine clumps during the year, and next spring produce an immense quantity of flowers, standing for about three years.—A. D.

2799.—**Keeping Rain-water Pure.**—Your correspondent "S. L. C." gives a description of "keeping rain-water pure in a simple, cheap and practical manner," as carried out at Knockholt, near Sevenoaks. The method adopted, which he explains, is almost general in every provincial town. The underground cistern with its pump in the yard, garden, or scullery is everywhere to be met with. But so far from keeping rain-water pure, it is in many instances the primary cause of rendering it unfit for use. Given an underground brick tank, cemented, &c., you must provide an overflow pipe for times of heavy rainfall, and this overflow pipe the builder connects with the house drains or sewer, for which latter it then becomes a simple ventilating shaft for polluting the water of the cistern; or, as I have sometimes seen, a stoppage occurs in the drain below the junction of the overflow pipe, and the sewage is backed up into the rain-water. When we recollect that rain-water gathered from gutters and downspouts of houses has first of all acted as the scavenger of these channels, in removing soot, the dung of birds, and decayed leaves of trees, beside other filth, we see at once the difficulty in procuring pure rain-water from these tanks where it must simply lie and decompose. In all cases I should recommend an above-ground receptacle, which admits of frequent inspection and systematic cleansing without the possibility of sewage contamination. If required for domestic consumption the filter must be regarded as a *sine quâ non*.—J. M., *Loughborough*.

2972.—**Cucumbers not Fruiting.**—Most of the Cucumber failures I have met with of a similar nature to "Enquirer's" were owing to planting in soil that was too light and rich, "deficient in minerals," and although such soils produce foliage, yet they seldom produce fruit in a satisfactory manner. Turfy loam enriched with a fourth, or in some cases a third, of old manure forms a good compost for Cucumbers.—E. H.

A Greenhouse Pillar Plant (Habrothamnus elegans argenteus); flowers red. (See p. 358.)

2900.—**Law Respecting Greenhouses.**—The questions whether greenhouses come under the Metropolitan Building or any other similar Act, and also whether they therefore come within the surveyor's jurisdiction, have just been decided by a case in the police court here. This case establishes conclusively that a greenhouse comes under the exempted buildings mentioned in the Act (18 & 19 Vict., cap. 122, p. 1144), even if it have a stove and piping for heating purposes. The Act specifies that "party walls and greenhouses, as far as regards the necessary woodwork of the sashes, doors, and frames," are exempted; and the magistrate in his decision particularly laid stress on the objects for which the structures were intended, viz., the growing and keeping of plants. The surveyor contended that it was a dwelling-house, because it was of a certain size, and because it had a stove and flues in it, and also because it had "brick panel walls," these walls, be it understood, being really the party walls of the garden, of which the house was built independently. All this was overruled by the magistrate's decision, and, as a penalty for being in the right, I have been mulcted in the cost of my defence, amounting to 30s.—T. BOOTH, *Hathershaw, Oldham, Lancashire*.

—— In reply to the query in last week's issue, surveyors have a right to interfere "within the limits of the Metropolitan Buildings' Act" with greenhouses, and they will not allow any portable greenhouse to be erected. I put up one and had to sink a foundation 24 in. under the ground and put 9-in. brickwork up to the sashes. I allowed

myself to be summoned first, and the magistrate at Worship Street distinctly stated that greenhouses came under the Act.—JOHN BELLINGHAM.

3037.—**East Lothian Stocks.**—Unless the weather should be very severe, the mats will be a sufficient protection, but it is damp that injures them more than cold. If the Stocks could be potted carefully, and when established introduced to the greenhouse, they will bloom very early in spring. But no matter how saved they will certainly bloom well next spring and summer.—E. H.

2974 and 2990.—**Drying Flowers.**—In answer to "Janet" and "Novice" respecting drying and preserving flowers, I beg to offer the following suggestions: Collect only good representative plants, taking leaves, flowers, and both kinds of buds if possible. This should be done in dry weather. Place the plants so gathered between sheets of absorbent paper. A very good sort which I have used with much success is that called Tobacco paper; it is easily procurable from any paper warehouse. Lay a sheet of this paper on a stout board; on this place enough plants to just cover it with a single layer; then add more paper and another layer of plants, and so on until all your specimens are disposed of, and place another stout board and about 80 lb. weight of stone or metal on the top thereof. The paper should be changed in twenty-four hours for some that is dry; afterwards change the paper every two or three days. When dry the plants may be stored away between sheets of newspapers till they can be mounted on cartridge paper. Flowers with very delicate corollas should be placed when fresh in a fold of tissue paper, and kept in it until dry. This saves them from getting torn. Plants so dried will keep their colour pretty well, generally speaking. There are certain plants which cannot, however, be dried so as to retain their original colours. Such plants as Sedums are best dipped in boiling water before being placed in absorbing paper, otherwise they are difficult to dry. They will even go on growing in the paper. When mounted the plants may be brushed over with a solution composed of 2 drachms of corrosive sublimate in 1 pint of spirits of wine. This keeps insects away; as it is very poisonous it must be very carefully used.—BOTANIST.

3046.—**Overgrown Wall Trees.**—The strength of the tree has gone upwards, and the sap, having made a channel there, can only be brought back by cutting the wild growth off, or bending it over the top of the wall and training it down the other side. The latter plan will be best if it can be done, but the tree would have to be headed down to induce it to break from the bottom and furnish the lower part of the wall.—E. H.

2902.—**Eucalyptus in Winter.**—Sometimes large plants of this stand the winter unprotected; your soil and situation must be unfavourable and cold. After your experience of the two last seasons I would by no means advise you to trust your large plant to the tender mercies of an ungenial climate, especially as by going to some little trouble you can safely protect it. I have seen trees and shrubs more tender than Eucalyptus protected successfully during severe frost in the following simple manner: Stick poles in the ground all round your tree about 3 ft. apart and 1 ft. taller than the tree is itself; now nail laths from the inside of one pole to the outside of the next pole crosswise about 6 in. apart all round. A couple of laths should also be nailed across the top to keep the framework together. The latticed space thus formed round the tree must be packed with a sufficient quantity of Moss or dry Fern to keep out the extreme cold. When severe frost sets in the top can be covered over with a mat or two. This if carried out will save your tree, a fact that should be of sufficient value to repay you for your trouble.—P. J. KANE.

2991.—**Vine Suddenly Dying.**—As the other Vines in the house are looking well and bearing a good crop, there must be something quite local for the Golden Queen to die in so strange a manner. I should think it might be ascertained by an examination of the border and the plant. Has anything interfered with the stem or main roots? A rat or even a mouse has been known to cause the death of a Vine by nibbling off the bark of the stem close to the collar.—E. H.

2801.—**Grass Going Brown.**—Almost any good gardener on the spot could advise you better, as the cause would most likely be easily perceptible. If it arises from poverty in the soil, top-dressings of manure will be serviceable; soot and guano applied in showery weather will do good. Are there any insects present at the roots of the Grass? You had better examine it.—E. H.

2715.—**Melons Rotting.**—They are probably kept too close. Ventilate as soon as the sun strikes full upon the frame in the morning; perhaps, as the days have been often dull, the plants have not had much air.—E. H.

2745.—**Moss on Gravel.**—Sprinkle salt all over the surface of the carriage drive, using from 2½ lb. to 3 lb. per square yard. It is best done in dry weather. The following is an effective dressing for destroying Moss or weeds: 14 lb. of salt and 14 lb. of sulphate of copper; dissolve in 30 gallons of boiling water and apply it hot.—E. H.

2887.—**Water Lilies in Bouquets.**—I should recommend "M. A. C." to try my plan, which has answered admirably. Put the buds into a basin of water, and stand in the sun or a warm place where they will soon come out; then take them out and pour a little thick gum arabic into the centre; it must be thick, so as it will dry soon, and when once dry the flower will not close, but remain open until it dies. I have also closed the end of the stalk with a little sealing-wax, which I find keeps them fresh.—N. C. W.

2836.—**Magnolia not Flowering.**—We think that the cause of the Magnolia not flowering will be found to lay in the sunless nature of the two last seasons. The wood has not matured; a hot summer would probably set things all right again.—C. B.

2996.—**Striking Roses in Water.**—Last year, about the end of August, I put four or five Rose cuttings in a bottle in water, and at the end of three weeks they were all rooted, when I put them into small pots, using a very light, turfy soil, giving them a liberal supply of water; in fact, keeping the soil as moist as possible until the plants had shown growth. Great care must be taken in potting the rooted cuttings, the soil to be gently placed over the roots. I have two nice plants treated in the above way.—J. C., *Whitley*.

2999.—**How to Improve Lawns.**—"A Learner" did not evidently pay any attention to consolidating the seed-bed sufficiently before sowing the seed. If the turf is sufficiently good it may be taken up where the ground has sunk, the place levelled up with earth, and the turf relaid, a few seeds being sown over it, and a light covering of leaf-mould given. If the turf is not worth lifting, level the sunken places with earth, sow seed thickly, and cover with leaf-mould.—CARTER & CO.

2982.—**The Bury Bug.**—Trombidium autumnale, the bury bug or harvest bug, is a minute Arachnid, which buries itself in the skin, causing what are commonly termed heat-lumps, which are accompanied by great itching and irritation. The best remedy is to examine the spot as soon as discovered, when a minute white speck will be found, which should be punctured and well pinched or squeezed. A drop of serous fluid will exude, and further irritation in a great measure prevented.—W. L. J.

—— In reply to your correspondent respecting the best way to cure the bite or sting of bury bugs, or harvest bugs as they are sometimes called in this neighbourhood, I have suffered from these pests recently, and found Spratt's Dog Soap a certain cure after one or two applications. Wash the parts affected, using plenty of this soap, and the itching will soon cease.—PRO BONO PUBLICO.

—— This appears to be what is more commonly known as the harvest bug, being rather numerous at harvest time. The insect buries itself in the skin, causing much irritation, and often sores. The best application is a warm decoction of the woody Nightshade (to be met with in many shady roadside hedges) or a little sal volatile, or else Goulard water, with a few drops of laudanum added.—CHAS. NEVISON.

Gloire de Dijon Rose.—I should advise "G. E. T." to bring down one of the strong shoots of his Rose to within a few feet of the ground, and next year, if it is budded on a Brier, to allow a shoot to grow from the root and re-bud it, leaving the old tree standing.

Slugs in Larder.—Put a saucer of milk or bread and milk on the floor when dark. An hour or two afterwards you will find the slugs feeding—perhaps six or eight round the saucer; catch and kill.—A. B. C.

Striking Roses in Water.—I have never found any difficulty in planting my Rose cuttings. I take them out of the water when the roots are about ½ in. long, and put them at once carefully in the centre of a small pot, making a hole for them, and covering lightly with mould about 2 in. deep, watering them freely afterwards, and protecting from the sun for a few days.—S. M. M.

2998.—**Cankered Roses.**—Maréchal Niel is, unfortunately, very subject to canker, and we know of no effectual remedy, and where a plant is badly infected we would prefer to destroy it and replace with another. You might, however, try the French remedy for canker in fruit trees, or burning with a hot iron. This may stop it, but we would certainly prefer to replant. It is not advisable to occupy good space with a diseased plant.—C

2973.—**Cactus Cuttings.**—Do not disturb the cuttings now, but wait until next April before potting them off. They may be kept in a cool greenhouse, from whence frost is excluded, or they may be wintered in a room. Sandy loam mixed with a little brick rubbish is the best compost for them. Pot firmly, and drain the pots well. Water moderately, and expose to the full influence of the sun during the summer, giving plenty of air. Cacti require a good roasting to mature the wood for flowering.—C.

2983.—**Propagating Clematis Jackmani.**—The Clematis Jackmani and all its fellow kinds are generally propagated either by means of layers—that is, pieces of the growth pegged down at the joints into the soil, and thus induced to root, or worked as grafts upon the roots of some common kind. The plants, when strong, may also be propagated by lifting and dividing the roots. Little growth is made after the bloom, as that is usually the termination of the season's product of shoots.—A.

2977.—**Cucumbers Being Eaten.**—Rats, in all probability; I suffered from the same last year.—H. S. YOUNG.

2984.—**Begonias Going to Seed.**—The seed-vessels of most kinds of Tuberous Begonias are very prominent before the flowers open, but the flowers themselves should last quite a week. Perhaps they have suffered from want of moisture at the root.—B.

2887.—**Water Lilies in Bouquets.**—The Water Lily closes naturally in the evening, but should remain open when cut during the daytime. To prevent its closing we have been informed that it is a good plan to slit the calyx all round, a method which is effectual in the case of the Gazania, which shuts up in the evening.—C.

2783.—**Gooseberry Caterpillar.**—Chaffinches and cuckoos destroy them; perhaps the cuckoo is the most voracious, but the chaffinches continue all the season feeding upon them. All small birds, or nearly so, with the exception of sparrows, eat them. I have 4000 Gooseberry trees, but very few caterpillars. Encourage small birds.—H. S. YOUNG.

2901.—**Mezereon Daphne.**—This is generally raised from berries sown in spring in a mixture of heath mould and rich sandy loam; border with a south aspect suits it best.—P. J. KANE.

3047.—**Insects in Manure Tanks.**—Insects will generate in stagnant water. If the liquid manure tank cannot be emptied try a little chloride of lime.—H.

3045.—**Fuchsia Buds Dropping off.**—Probably the roots are too well supplied with water. If the soil gets sour from stagnant moisture the buds will fall. Are there any worms in the pot?—E. H.

3048.—**Woodlice and Earwigs.**—Place a toad or two in the greenhouse to eat the woodlice; also trap them by placing a handful of dry Moss or hay in a few empty flower-pots laid on their sides under the stages. Examine the pots occasionally, and kill the insects. Cut pieces of Beanstalks 8 in. or 9 in. long, and lay where the earwigs congregate. They will hide in the hollow stalks, and may be puffed out into hot water and destroyed.—H.

3040.—**Unfruitful Grape Vine.**—It is a common practice to plant Grape Vines without making any preparation or doing anything to improve the site, and, of course, under such conditions the Vines are long in gathering strength to bear fruit, especially on a west aspect. As the soil is gravelly, mulch with some old manure to be forked in in November. When the leaves fall prune back to firm wood.—H.

3041.—**Plants not Flowering.**—The bulbs named like all bulbs generally require a season of growth, and then a resting-time with cooler, dryer treatment. If they fail to flower it is through some error in attending to their wants. Turfy peat and loam with some sand and charcoal will grow them well.—H.

3035.—**Annuals for Spring.**—Sow at once the following; it is full late: Limnanthes Douglasi, Nemophila insignis, N. maculata, N. alba, Saponaria calabrica, S. alba, Silene compacta, Virginian Stock (red and white), Collinsia verna, Bartonia aurea, Asperula azurea setosa, and Myosotis dissitiflora. In future sow the Myosotis about the end of July.—E. H.

2995.—**Peaches and Nectarines Failing.**—Are the Peach trees free from red spider? Their presence would cause the leaves to fall, and when that happens, from whatever cause, the fruit would be worthless. Overdressing with manure water, so as to close up the pores of the soil and cause stagnation, paralysing the action of the roots, will produce pretty much the same effect.—E. H.

2997.—**Nasturtium Pods for Pickling.**—The seed-pods of the dwarf Tom Thumb Nasturtium may be safely used for pickling if gathered young enough.—E. H.

3050.—**Soluble Phenyle.**—Write to Morris, Little & Son, Doncaster, and they will direct you to the agent most suitable. The price is 10s. a gallon in a 2-gallon iron drum, but 1s. bottles are to be had.—E. G. H.

—— The soluble Phenyle enquired for is perhaps absolute Phenol, which consists of carbolic acid in a state of extreme purity.—J. F. M.

3051.—**Drying Tobacco.**—"Tobacco Culture;" practical details published by Orange Judd, editor of the *American Agriculturist*, 41, Park Row, New York, 1863; price 25 cents. This publication gives the information required by "Good Hope."—OMBU.

2982.—**Berry Bugs.**—If these are the same as what are called harvest bugs I can recommend mercurial ointment rubbed into the places where the creatures have buried themselves. Many years ago I suffered severely from their attacks, and used the above remedy by the advice of a doctor with perfect success.—E. G. H.

—— In answer to your querist, Thos. Lockhart, I would advise him to apply sweet salad oil, previously made hot, to the bites of the insects he mentions, which I should say were what are called about here harvest bugs; the oil to be well rubbed on the bitten places with the hand.—OXONIENSIS.

3039.—**Berries for Winter Decoration.**—Put any berries clean and dry into a strong pickle of brine and water in a deep pot with a layer of mutton fat on the top to exclude air; in this way they will keep for months. When wanted take out and dip in fresh cold water and dry on a cloth.—C. H.

3052.—**Daisies on Lawns.**—A pinch of salt on each root is the quickest and most effectual way of killing Daisies, &c. The Grass will look shabby for a time, but rain will restore it.—C. H.

3001.—**Carnations and Picotees.**—Carnations that have done blooming, taken up now and potted in good rich soil and wintered in an ordinary greenhouse temperature, will bloom freely in April. To ensure an earlier bloom the perpetual varieties should be used. Of ordinary Carnations the golden-yellow variety Florence will be found very free and strong, combining size of flower with quantity of bloom.—J. A. B. W.

3127.—**Tomatoes in a Vinery.**—*R. H. M.*—Tomatoes can be grown in a Vinery, but the shade of the Vine leaves will generally prevent a very good result being obtained; to do them justice they should have a little glass compartment to themselves.

3128.—**Carnation Cuttings.**—*H. B.*—Carnations can be propagated in the way you name, but for general purposes layering is the most certain method. Tree Carnations should be propagated by cuttings taken in the months of April or May; with the assistance of a little heat they strike root freely then.

3129.—**Pelargonium Cuttings.**—*H. B.* — These should no longer be exposed to heavy rains, but place them at once in the greenhouse, and give them abundance of air.

3130.—**Liquid Manure for Maiden-hair Ferns.**—*Rose.*—Liquid manure is dangerous unless applied with great judgment to Maiden-hair Ferns, and we do not advise you to use it. Re-pot your plants in the spring, using a mixture of some good fibrous peat, loam, well decayed leaf-mould, and sharp silver sand as a compost for them, and put plenty of drainage in the bottom of the pots.

3131.—**Camellias Losing their Flower-buds.**—*J. B.*—Although you say your plants have not suffered from want of water at the root, we are of opinion that drought is the real cause of the buds falling off from otherwise healthy plants. The ball of earth surrounding the roots may appear moist on the top and yet be as dry as dust in the middle. See into this matter, and if you find such to be the case, stand them in a tub of water until thoroughly soaked. Are the plants in bad soil, or in very small pots?

3132.—**Hot Water not Circulating.**—*Constant Reader.*—We should say the cause of your hot-water apparatus not working satisfactorily is to be attributed to a lodgment of air in an elbow or syphon. Have it inspected by a competent man, and additional air pipes added thereto if requisite.

3133.—**Lobelias and Musk.**—*Dicky Sam.*—Lobelias and Harrison's Musk can be propagated with the greatest ease from cuttings, and the Musk can also be increased by division of the root.

3134.—**Vine Shoot.**—*Fylde.*—From the appearance of the Vine shoot sent we should say your Vines are infested with black thrips. These insects are most injurious and difficult to eradicate. After you prune the Vines, dress the stems over with a strong mixture of Tobacco water, soft soap, and sulphur, and thoroughly cleanse every portion of the interior woodwork of the Vineries with hot soap and water.

4135.—**Potatoes Eaten by Insects and Slugs.**—*Potato.*—Apply copious dressings of soot and lime, and in the winter trench the ground roughly, so that the frost may penetrate freely. This probably will do good.

3136.—**Unhealthy Muscat Grapes.**—*W. C. M.*—Your Muscat Grapes appear to be suffering from a bad attack of "rust," a state of things generally brought about by cold draughts of air or by careless handling when the berries are thinned, and we also think the roots of your Vines must be in a cold, uncongenial soil. Muscat Grapes require a warm well-drained border for the roots to grow in, together with a high temperature for the top.

3137.—**Hollow Celery.**—*One Interested.*—Celery often becomes hollow or pipy, as it is termed, from having had an insufficient supply of water at the root during its growing season. A good well enriched loam is the best soil for it.

3138.—**Primroses Dying.**—*Rustoni.*—From what you say your Primroses are evidently planted in very poor ground, and are therefore starved. Take them up at once, and well manure and dig the land; then divide the Primrose roots if they are large, and replant, and you will probably have better success in the future. Your other queries are of so trivial a nature, that we cannot afford space to notice them.

3139.—**Wintering Alternanthera.**—*F. D. W.*—To winter this plant well it should be afforded during the cold months a temperature of 50° or 55° of heat, and placed near the glass. If kept in a much lower temperature the chances are that you will lose your stock.

3140.—**Humea elegans and Salvias.**—*Datchett.*—Neither the Humea nor the kinds of Salvias you name are hardy, and therefore, of course, cannot be grown out-of-doors during the winter.

3141.—**Small Greenhouse.**—*Lincoln Amateur.*—In a greenhouse of the dimensions given, and with the present heating power at command, it would be useless for you to attempt to force the vegetables, &c., you name. Balsams do not bloom in the winter.

3142.—**Fixing Hot-water Piping.**—*A. B. T.*—The best way to fix hot-water piping together so as to be easily taken apart again is to use the vulcanised india-rubber rings. They can be obtained from any hot-water engineer, who will also no doubt show you how to use them.

3143.—**Dirty Leaves on Lemon Tree.**—*G. C.*—Your Lemon tree is evidently infested with brown scale. The best remedy you can adopt is to thoroughly wash the foliage with a sponge, using plenty of soft soap and warm water. This operation should be frequently repeated.

3144.—**Cuttings of Fuchsias and Geraniums.**—*Novice from the Cape.*—Fuchsias and Geraniums struck now can be easily wintered in the window of any ordinary sitting-room. During the dull winter months they will not require water more than once a week.

3145.—**Greenistas, Camellias, and Azaleas.**—*Constant Subscriber.*—It is not safe to leave these and similar greenhouse plants growing in pots out of-doors longer than the end of the present month.

3146.—**Geranium Cuttings Turning Black.**—*A Learner.*—From what you say about your Geranium cuttings we should think you have given them an over-abundance of water. Try the effect of keeping the soil moderately dry, and carefully remove all decaying foliage as soon as it is observed.

3147.—**Soil for Fuchsias.**—*Horological.*—The best soil for Fuchsias is a mixture of, say, two-thirds light sandy loam and one-third decayed manure and leaf-soil, with the addition of just a little sharp silver sand. When potting your plants use plenty of drainage, as although the Fuchsia delights in moisture, it greatly objects to any stagnant water about its roots.

3148.—**Soap-suds.**—Are soap-suds any good for greenhouse plants? or would they be injurious?—M. P. [Soap-suds carefully used in a diluted form are excellent as a wash to destroy insects on plants, but certainly dangerous to water the roots with; by no means use them for that purpose.]

3149.—**Figs and Tomatoes Cracking.**—*Evelyn.*—The cause of this is generally to be attributed to either excess of moisture in the atmosphere or at the root. Avoid either extreme.

3150.—**Cinerarias.**—*C. A. B.*—Suckers should certainly be removed from Cinerarias, and if you wish to increase your stock these suckers will quickly strike root and make excellent plants.

3151.—**Cabbages and Cauliflowers Clubbing.**—Can you suggest a remedy for Cabbages and Cauliflowers clubbing at the roots? mine have all gone so this year. Can anything be put in the land to prevent the same?—SUBSCRIBER. [Plant as much as possible on fresh land, but where this cannot be done good dressings of soot and lime should be dug into the ground before planting.]

3152.—**Cutting Down Geraniums and Fuchsias.**—*W. H.*—You may cut down Geraniums now, but leave the Fuchsias until spring.

3153.—**Calceolarias Dying off.**—*Accrington.*—Very probably you over-water your Calceolarias and allow them to become infested with green fly. These causes would both tend to destroy your stock.

3154.—**Chrysanthemums and Wallflowers.**—*R. C. S.*—Cuttings of Chrysanthemums had better be kept in their pots during winter. Wallflowers may be planted out.

3155.—**Exhausted Soil.**—*S. A.*—You should endeavour to have a portion of the old exhausted soil carted away from your garden and replaced with some fresh turfy material, and then well and deeply dug over and manured. Bulbs might then be planted, and should do well.

3156.—**Passion-flower Leaves Spotted.**—*A Constant Reader.*—The leaves sent show evidently that your plant is attacked with red spider. You may check it by copious and frequent syringings with clean water, and also see that the roots are well supplied with moisture.

3157.—**Cutting Down Pelargoniums and Fuchsias.**—*G. M. F.*—Pelargoniums should be cut down in the month of August, and when they have made a little fresh growth should be repotted. Fuchsias may be kept rather dry during the winter, and cut back and repotted in the spring.

3158.—**The White Anemone** (Anemone japonica alba).—*Usurious.*—We should say you will have no difficulty in obtaining this Anemone from some nurseryman in your neighbourhood, and the price should not be large.

3159.—**Grub on Fuchsia Leaves.**—The leaves of my Fuschias have this season been attacked with a small brown grub. I have had also a quantity of them on other plants in my Vinery and greenhouse, and wherever they are present the foliage seems to be killed. They are found in most instances rolled up in the leaves in a kind of cocoon, and grow about ½ in. long, and about as thick as fine twine. Can any one suggest a good mode of extermination and prevention?—G. S. [Try syringing with rather strong Tobacco water, or, where practicable, dust the foliage affected with soot.]

3160.—**Propagating the Cardinal Lobelia.**—Will you inform me how to propagate Lobelia cardinalis?—EDITH ATTWOOD. [Divide the roots in early spring.]

3161.—**Brussels Sprouts.**—*W. B.*—These require no special treatment at this season of the year; to remove any of the large leaves would be the worst thing you could do.

3162.—**Heating a Greenhouse.**—I have a greenhouse 31 ft. long and 9½ ft. wide, and would feel obliged if any one could recommend the best kind of paraffin or other oil stove or lamp for heating the house during the winter; also if more than one would be required for the size of the house, which is built in an exposed situation.—L. [The only efficient way of heating a greenhouse of the size named that we can recommend is either by a well constructed brick flue, or, better still, by hot-water pipes attached to a small saddle boiler.]

3163.—**Mildewed Peas.**—*T. D. W.*—The Peas have become mildewed through insufficient depth of soil, manure, and moisture.

3164.—**Glazing Without Putty.**—*A. W.*—This is said to answer well; you had better try and see a house glazed in this system before you attempt it yourself.

3165.—**Rubbish in Water Tank.**—*C. M.*—It is simply an accumulation of leaves, sticks, and dirt, which have been washed in from the roof of the house, and which may be found in any rain water tank which has not been cleaned out for some time.

Names of Plants.—*R. C. S.*—Achillea Ptarmica fl.-pl.——*G. F. W.*—We cannot name Coleus.——*Barrowby Lane.*—French Lavender (Lavandula spica).——*L. C.*—Impatiens grandulifera.——*Novice.*—We cannot name Coleus.——*J. J.*—Tropæolum speciosum.——*J. S.*—Chrysanthemum Leucanthemum var. maximum.——*B. B.*—The fine pods of Peas sent appear to be of the old matchless Marrow type, but such things cannot be named with any certainty.——*W. R. T.*—Maurandia Barclayana.——*F. D. W.*—Eupatoria ageratæoides.——*Heather.*—Tropæolum speciosum.——*Constant Reader.*—1, Fuchsia globosa; the other flower sent was dried up beyond recognition.

Names of Fruits.—*J. R.*—Apples: 1, Dumelow's seedling; 2, Yellow Ingestre.——*R. T. (Weymouth).*—No one could tell you the name of your Apple without seeing specimens of the fruit.

QUERIES.

To Querists.—*All questions are inserted or answered in these columns free of charge, provided the following rules are observed: 1.—Write clearly and concisely on one side of the paper only. 2.—Use a separate sheet of paper for each query. 3.—Give full name and address, with any nom de plume or initials you may wish used in the paper. Questions only of interest to the persons asking them should be accompanied with a post card or stamped addressed envelope for reply.*

3166.—**Lycopodium Moss.**—How can I grow the above and increase it for hanging baskets? Also what treatment does it require to keep it alive during winter? Can I do so in a cool Fernery? Or will it do better in a glass case inside the window of a living room?—J. B. M.

3167.—**Winter Salads.**—I am desirous of using part of a greenhouse for growing a few winter salads and vegetables; can any experienced person tell me the kinds that can be readily grown? I have one bed about 10 ft. by 3 ft., soil varying from 9 in. to 15 in. deep, with hot-water pipes beneath, light, and near the glass, and others smaller and more shaded.—A SUBSCRIBER.

3168.—**Varnishing Window Boxes.**—I am making some window boxes and covering them with Virgin cork; will any reader tell me how to varnish the cork of a light Oak, or its own natural colour, so as to resist the weather, and prevent it getting black with dirt?—G. M. WEEKLEY.

3169.—**Keeping Window Plants in Winter.**—Will some one give me information how to keep Geraniums, Calceolarias, and Fuchsias during winter without heat? They are at present in a parlour window where there is no gas, and seldom any fire in winter. I have a spare room, but with only a small window.—SYDNEY RANDAL.

3170.—**Colouring for Fruit Walls.**—I am now having about 50 yards of fruit wall built; aspect a little to the east of south. I intend to colour it black, and I should like to gas tar it, as I believe that nothing will keep away insects so well as gas tar. Will you kindly say whether there is any objection to using this on a fruit wall? I may add that I shall train the trees on horizontal wires on the French system, and iron brackets 2 ft. wide will be built into the wall at distances of, say, 5 ft., just below a 3-in. coping. On these I shall place in spring, when the buds are showing, light, movable wooden frames, covered with oiled or varnished calico, as defences against frost. May I ask for criticisms on my scheme?—J. E. VAUX.

3171.—**Flowers for Fern Case.**—What flowering plants would be suitable for growing in fern case indoors, and which of them ought to be purchased at this season? The case is 36 in. by 20 in., and 24 in. high. Could any of the cheaper Orchids be got to flower in such a case?—CLYDESDALE.

3172.—**Failure of Ixias and Sparaxis.**—I have grown these beautiful Cape bulbs for the last four years with success, as regards the growth of the foliage, but not a single flower have they produced. The bulbs I was growing were those mixed varieties, which are mostly very small roots, and which look as if they were unable to produce flowers. As I am going to grow them another season, will any one give me a few hints how to induce them to flower?—J. HENRY.

3173.—**Climbing Rose Trees not Flowering.**—I have a climbing red Rose tree which has not blossomed for two or three years, the leaves all falling off very early in the autumn. I should like to be informed of some remedy. It is situated in rather a confined position, and is facing east.—G. M. F.

3174.—**Cutting Rhododendrons, &c.**—I have in a small plot of ground in front of my house a rather large Rhododendron and two Aucubas, all of which I wish to reduce in size. Will it be right to cut them down, say some 5 in. or 6 in., and if so, at what time of the year?—G. M. F.

3175.—**Renovation of Soil.**—I have a piece of ground which is rather heavy, although it looks like good loam, and is infested with worms and slugs. I intend digging in some ashes, soot, lime, and salt, to lighten it and clear it of vermin. Would it be doing any good to dig in a quantity of leaves from a Pear tree which I have in an undecayed state? If not, what is the best thing to do to utilise them?—ALPHA.

3176.—**Conservatory Plants.**—I have a conservatory 20 ft. by 14 ft., and 14 ft. high in the centre. All four sides and roof are glass and wood. At present it is empty. I shall be very much obliged for any hints as to filling it up with effective plants, and what evergreens, Ferns, creepers, &c., to get, so that it may look well all the year round without constant expense in manual labour. There is a good supply of water in my conservatory. Would some large plants, such as Tree Fern, India-rubber, and Palm look well planted in the centre? Any information will be thankfully received. The house is thoroughly heated by hot-water pipes, and the floor is tiled.—A CONSTANT SUBSCRIBER.

3177.—**Kitchen Apples.**—Can any of your readers living in the fens of Lincolnshire or Cambridgeshire tell me from their own experience about six of the best kitchen Apples to grow as standards in that district?—A. B. G.

3178.—**Cloches or Bell-glasses.**—Will any one kindly inform me where the cloches or bell-glasses so much used now by the market gardeners near London are manufactured? or at what retail shops they can be obtained at a reasonable price?—J. S.

3179.—**Removing Rose Trees, &c.**—Is it the proper time to remove Rose trees, Ferns, and Lily of the Valley? The Lilies will be removed from a west aspect to a shaded south-east one.—W. D.

3180.—**Quick-growing Plant.**—Will some reader kindly inform me of a very quick-growing plant that would keep green all winter? and also, if now is the right time to plant Honeysuckle?—W. D.

3181.—**Brier Stocks.**—Can any reader inform me where I can obtain Dog Rose or Brier Stocks? and the cost per hundred?—F. J. R.

3182.—**Treatment of Eucharis amazonica.**—Can any one inform me how to treat Eucharis amazonica? Will it do in a greenhouse—as that is the only place I have to grow it in? When is the time to divide it? and what kind of soil is the best for potting it in?—AMAZON.

3183.—**Spiræa japonica.**—How am I to treat these so as to have them in flower about March?' I have very little heat at command. What time in the spring would they flower if left outside, or kept in a cold frame?—BERKS.

3184.—**Coping for Walls.**—What is the best kind of cheap coping to cover the top of a garden wall—to protect it from the penetration of wet? I recollect seeing somewhere that a mixture of boiling tar and, I think, lime and sand forms a good covering, but I cannot remember particulars or the proportions.—HORTUS.

3185.—**Seedling Calceolarias.**—I am about potting into 3-in. pots some Calceolarias raised from seed sown in July last, and, having no frame or greenhouse, should be glad to know if they would do in a back room of my dwelling-house, close to a sunless window, and what is the proper soil for them and treatment through the winter, and when should they bloom.—HORTUS GRAL.

3188.—**Insecticide.**—Your correspondent "J. W." states that he has found castile soap an effectual insecticide, but will he kindly say the quantity of water to 1 oz. of the soap. I tried 1 oz. to a bucketful, but the thrips next morning seemed to have treated their immersion therein as a practical joke, and were grazing as actively as ever.—J. ROBINSON, *Southport*.

3189.—**Digging up Parsnips on Strong Land.**—Is there any tool by means of which Parsnips grown in strong land can be raised without injury? I have some acres, and they have penetrated to such a depth that I anticipate much trouble in digging them up.—E. L.

3190.—**How to Collect Lobelia Seed, &c.**—Can any reader inform me the proper way to collect, and the best time to sow the seeds of Lobelias, Phloxes, Balsams, and Perilla?—A YOUNG BEGINNER.

3191.—**Pruning Gloire de Dijon Rose.**—Writing of the adaptability of this Rose for walls, your correspondent "Hartside" says it needs special pruning to bloom well. Perhaps he will kindly explain of what the special pruning consists.—QUERCUS VIRIDIS.

3192.—**Pine Trees and Shrubs.**—Will any of your readers kindly tell me what Pine tree is considered the hardiest and best suited to a very exposed aspect quite close to the sea and facing the east? I should be glad also to know what shrubs do best for seaside planting? Are Phillyreas very hardy?—SUBSCRIBER.

3193.—**Striking Cuttings without a Greenhouse.**—Having no greenhouse, I have potted cuttings of Geraniums and Calceolarias, and distributed them throughout my house upon the window-sills. Will they do there? and if so, ought the windows to be left open daily? How soon ought they to be potted off singly into their own pots?—CHAPLAIN.

3194.—**Keeping Rain-water Good.**—I have two water barrels at the end of my cottage for the purpose of catching and storing the rain-water. The water, however, after a time gets very bad; a greenish slime gathers round the sides of the barrels, and laterly the water has become full of minute living forms. How can this be prevented?—J. B.

3195.—**Climbing Plants.**—Will any of your readers of experience tell me the names of some climbing plants (evergreen preferred) to grow round and to cover the uprights of a large summer house so as to shade from the sun, and also partly keep off rain?—P. P.

3196.—**Flowering Gladiolus.**—Will you or some reader kindly tell me how to make Gladioli expand the whole of their flower-buds at the same time? I have seen several lots of Gladioli, and they were one mass of fully expanded blooms from bottom to top of spike, the bottom blooms looking as fresh as the top ones. Mine (in pots), three bulbs in a 10-in. pot, have had splendid individual blooms; three bottom buds on each flower-spike expanded beautifully, and lasted three or four days, and then began to fade, and as they faded the three buds above them began to expand, and so on to the top of the spike. I never had more than three buds fully expanded at the same time on one flower-spike.—A LEARNER.

3197.—**Insects in Fern Cases.**—I find that some of my cases, although well ventilated, are ravaged by some small insect; I notice a very small cast on the surface of the earth. How can these be destroyed without damaging the delicate fronds?—J. F. M.

3198.—**Gloire de Dijon Rose Withering.**—I should be obliged if any one would tell me why the flowers of my Gloire de Dijon Rose suddenly wither without any reason before they are full blown. The tree gets sun most part of the day, and has no sign of insects or such like upon it.—BUTTERFLY.

3199.—**Tortoise Stove.**—Can any of your readers tell me from their own experience whether the smaller size No. 1 of the tortoise stove may be depended on to burn (with proper management) through the night, or nearly so, in winter?—A. B. G.

3200.—**Properties of the Auricula.**—I am grateful to "J. C." for his clear and valuable description of the essential points of a really good and correct flower. I, however, fail to comprehend the meaning of these words: "In the Alpine class the flowers have no paste." For the raiser of the Alpine Auricula Queen Victoria thus refers to that word, "good circular straw-coloured paste, bleaching to white," and the word is also used in the description of many other Alpine Auriculas. Perhaps you will allow me to repeat my question in part. What is the exact dividing line or difference between a "Self" Auricula and an Alpine Auricula?—BERG.

3201.—**Hardy Annuals.**—Will any reader kindly inform me what hardy annual seeds I can sow now for spring flowering in the open ground, having no greenhouse of any kind?—NOVICE FROM THE CAPE.

3202.—**Tea Roses.**—I have some Tea Roses in pots but they have been a failure this year. They are grown in the front room of the house and get the morning sun; no gas is burnt in the room, and they receive plenty of air, and are watered regularly. If any one can give me some advice I shall be very glad.—HOROLOGICAL.

3203.—**Gloire de Dijon Rose.**—"Hartside" says "Gloire de Dijon I should think one of the best wall Roses, though it needs special pruning to bloom well." Will "Hartside" oblige me by telling when and how to prune it? Is a different method of pruning required for each of the systems of growing it, viz., when on its own roots, or budded on the Manetti standard or seedling Brier stocks?—W. W. R.

3204.—**Cauliflowers in Covent Garden.**—Will any one kindly inform me the name of the large white Cauliflowers now selling in Covent Garden Market? and any hints respecting growing them in north Yorkshire will oblige.—J. D.

3205.—**How to Destroy Slugs.**—I should be thankful to know what is the most merciful way to destroy slugs and snails.—E. G. H.

3206.—**Plants for Baskets.**—I have a window facing due south which gets the sun from morning until evening every day, and would like to furnish it with hanging baskets. Will any one tell me what plants to fill them with that will bloom in winter? I should like them to trail down from the basket.—BUTTERFLY.

3207.—**Overgrown Wall Fruit Trees.**—Can any of your readers help me out of a difficulty with regard to two wall fruit trees of mine? The trees in question have evidently been left unpruned for two or three years, and the consequence is they have grown wild and possess very few side branches, whilst at the top they are covered with large shoots which overhang the wall. I do not know whether to cut the shoots at the top of the tree back to the stock, or to prune them off entirely by cutting through the stock just below them. The stock at that point is about 1¼ in. in diameter. If it is advisable to prune, when should it be done?—E. H.

3208.—**Winter Decorations.**—I want a plant (not flowering) to look fresh and green all winter for the table. Would the Golden Feather keep its colour?—B. B.

3209.—**Weeds on Gravel Walks.**—Will any reader kindly tell me a remedy for weeds on gravel walks? Refuse salt has been tried many times, but it only apparently kills the weeds, and they soon appear again stronger, and in greater numbers than before.—BUTTERFLY.

3210.—**Moving Apple Trees.**—Would it be safe to remove to another part of the garden a row of Apple trees about 9 ft. high which have been planted nine years, and have never been root-pruned? What would be the best time for doing it?—AVE.

3211.—**White Lisbon Onions.**—I have over 2 acres of Onions, the seed of which was purchased as White Spanish; they prove, however, to be White Lisbon, and although they are with this glorious weather swelling a good deal, very few will, I fear, be marketable. Will any one advise me what to do with them? If I trench them in will they be useful next spring as Scallions?—E. L.

3212.—**Cucumber Disease.**—Can any of your readers of experience in Cucumber growing give me the benefit of their advice as to the best course of treatment for the eradication of the Cucumber disease or murrain? I never saw it before I came into this part of England (Lincolnshire), and have now suffered with it for six seasons running.—K. W.

3213.—**Culture of Bouvardias.**—Will one of your contributors kindly inform me through the medium of your paper the best method of propagating and growing Bouvardias?—E. R. T.

3214.—**Window Plants.**—I am anxious to know what plants can best be grown in a window-box during the winter. Perhaps one of your numerous subscribers may be able to inform me.—A SUBSCRIBER.

3215.—**Climbing Red Tropæolum.**—"Heather" will be glad to know how the small red climbing Tropæolum which flourishes so well in Scotland can be cultivated with hope of success in a garden in the north-east of Somersetshire.

3216.—**Herbaceous Plants to Blossom in Autumn.**—"K. S." would be very glad if any one would give her a list of herbaceous plants to blossom in autumn. During the summer, a bed skirting the lawn at a distance facing south with high fence at back has been gay with Nasturtiums, Sweet Peas, Mignonette, &c., but now their beauty has gone, and the bed looks ragged and unsightly; therefore, "K. S." would be very glad if some one would tell her what plants could take their place.

POULTRY.

Remarkable Egg.—A day or two ago a buff cochin hen of medium size laid such an enormous egg, that I weighed it, and found it to be 5⅛ oz. As it was of an unusual shape (both ends being nearly alike), I wished to blow it, so as to preserve the shell. In pricking the ends for this purpose the needle came against a hard substance, and after blowing out the white and yolk, I chipped away one end, and found within a perfect egg with a very hard shell; this I have also blown to preserve it. The circumference of the outer shell is 7⅛ in., and 8⅜ in. round the oval. That of the inside egg is 5 in. and 5⅞ in. respectively.—A. Z.

Minorca Cock.—"Wood B.'s" Minorca cock to be a good one should possess the following points: Comb large, firm, and perfectly upright, of a bright red colour, and evenly serrated; ear-lobe pure white, and of a neat round shape; face bright red, instead of white, like the Spanish, and not so largely developed as the latter breed. His carriage must be bold, and tail large and full and carried very upright, with sickles well curved. Legs short and of a dark leaden colour. Prominent breast; short broad back; rather long neck, but well covered with hackle. The plumage should be entirely black with plenty of green lustre.—AUDALUSIAN.

Houdans.—"Constant Reader" will be wiser to depend on Brahmas for eggs in winter than on Houdans. The former are without doubt our finest winter layers, although they are run pretty close by the Plymouth Rocks and Dominiques. But Houdans are not, strictly speaking, winter layers; in fact, by many are not considered first-rate layers at any season of the year; but a great deal depends on the locality and conditions under which they are kept. Whatever breed be kept for winter laying, they must be young; old birds never lay well between moulting and spring time.—AUDALUSIAN.

Vermin in Fowl's House.—Use a quart of paraffin to a gallon of limewash, and apply to the perches under and over, as well as the walls, and scatter sulphur freely in the nests.—MAUD.

Ducklings going Lame.—Having purchased a number of ducklings this summer, I found after having kept them for a period of three months that two of them were quite unable to walk in any way; it is not the cause of any blow or any other wilful damage. The whole batch were in a state of good health and were perfectly strong when purchased. I would feel greatly obliged if any reader would give cause and remedy.—IGNORAMUS.

Broody Hens.—In answer to "J. H. B." I beg to say when my hens want to set I put them in a rabbit-hutch that I have for a few days; it is only 14 in. in height, so is a rather uncomfortable place for them, and I think stinting food keeps them on the alert.—D.

—— Keep the hen wishing to sit well away from her nest for two or three days, and if it can be arranged let her sleep out-of-doors for a couple of nights.—M. T.

BEES.

Taking Honey from Bees.—Last week I wished to take some honey from a hive we have left untouched the last two summers. I tried the plan of driving the bees. It was easily done, and in twenty minutes they had vacated the old hive without loss of bees or stinging anyone. The hive I found full of very thick comb, nearly black, and almost empty, excepting a few inches round the top, which was light, and contained about 2 lb. of good honey. The bees, in number about equal to two or three swarms, have settled in the new hive. Will some one kindly inform me if the comb is usually so dark and empty after a good summer? Ought the comb to be left the first season, as I have another hive and should like advice before disturbing them?—AMATEUR BEE KEEPER.

Starting Bee Keeping.—Would "Apiary" kindly tell me whether the present month is a suitable time to commence bee keeping? and whether, with the aid of a super, honey could be obtained this year (bee food being supplied)? also the average cost of hive and swarm?—KENSINGTON.

Hornet, Humble Bee and Wasp.—Cacynen, Gwenynen wyllt, Gwenynen meirch, are the vulgar Welsh equivalents to the above respectively; but in different parts of Wales they are known by other names, there being in the language nine different words to represent the same.—LLANILAR.

AQUARIA.

Aquarium Difficulties.—I am under an obligation to E. Step for replying to my inquiry. He asks if I am certain no other enemy was placed in my aquarium, and to this I reply in the affirmative—simply three river minnows and a few tadpoles. I had removed them into a bell-shaped glass from my largest tank, as I feared it was overstocked, and they had only been together for a day and a night. Had I introduced any insects or beetles I might have drawn my conclusion at once, as I had done on a very recent occasion, when I placed a great water beetle in its larvæ state amongst my favourite fish, which was attended with fatal results. May this be a caution to all keepers of the aquarium. With respect to the sticklebacks, they certainly travelled a long distance in a limited space, but were only confined for about 2½ hours, and when put into the large tank none of them had died in transmission, and for a few days seemed to thoroughly enjoy their new habitation, and then began to die off one by one, till now and since my communication was made they have all shared the same fate. As this is the fourth attempt at keeping these lively inhabitants of the water without success, it passes my comprehension where the direct fault lays, for they were fed frequently, principally with worms, an ample supply of vegetation was provided, and a fountain almost continually playing to keep the water fresh.—NEWT.

HOME PETS.

Cage Birds Out of Health.—I have kept, bred, and studied cage birds for the past fifteen years or more, and I have necessarily at times been somewhat perplexed as to what course to adopt when some of them have been on the sick list. Now one of the most troublesome complaints from which birds so frequently suffer, and which, unfortunately, if not taken in time carries off so many, is inflammation of the bowels. This may be caused from a variety of causes, viz., cold, through exposure to draughts, &c., eating stale or unsound food, drinking impure water, eating stale green food, &c. I have tried numerous remedies with very doubtful or partial results. During the present year, however, I have tried a (to me) new remedy, and proved it most effectual. I have this summer cured five birds, and my object in now writing is to ask "A. d'A." or any other correspondent equally interested in the feathered tribe, if they have not already done so to give it a trial, and let us know the result. Directly I see a bird sitting moping and all of a heap on the perch, I mix as much Epsom salts as will cover a shilling, magnesia to cover a sixpence, and carbonate of soda to cover a threepenny piece, each piled up, in about a breakfast cup full of water. I then give one half in the water glass, and if it is very bad I give the remainder the next day; if not very bad miss one day, and give the remainder on the third day with clean fresh water between, but in this matter I am guided entirely by the apparent severity of the symptoms, and continue this treatment just as long as requisite, that is, until the bird resumes its wonted sprightliness, which I have found to be in about four or five days.—F.

GARDENING
ILLUSTRATED.

VOL. II.—No. 82. *SATURDAY, OCTOBER* 2, 1880. **PRICE ONE PENNY.**
REGISTERED FOR TRANSMISSION ABROAD.

NATURAL GARDENS.

RESPECTING the accompanying illustration, it is not necessary to write much, for the engraving itself teaches more than the pen can describe. It teaches us that in order to have a beautiful, natural, and enjoyable garden, we must neither have sharp edgings nor formal borders or beds, but a perfect harmony of luxuriant vegetation, which must be allowed to have pretty much its own way. It also shows us that arches of Roses over walks are among the many

A GARDEN OF ROSES AND HARDY PLANTS.

beauties of a garden when made in a proper manner. They are usually made about 4 ft. wide, the width of the walk, and 6 ft. or 7 ft. high. This is wrong. They should be at least 12 ft. wide at the bottom, and 8 ft. to 10 ft. high in the centre; there is then room for Roses or other climbers to extend themselves, and pruning and training become to a great extent unnecessary. We have seen such arches used with excellent effect over borders of hardy plants. The borders were, say, 6 ft. or 8 ft. wide, with a walk 4 ft. wide between them; at the back of each border a trellis 6 ft. high, covered with Roses, Clematis, &c., and from these trellises sprang arches at intervals of, say, 20 yards. These were covered with luxuriant Roses, Honeysuckles, Jessamines, Clematis, &c., and thus made a kind of covered way through the hardy flower garden.

ROSES.

SCENTED AND SCENTLESS ROSES.

Sweet-scented Roses.—Having ascertained that I had sixteen varieties of scentless Roses in my garden, I made out a list of these, and, at the same time, another list of the most popular kinds grown which really did possess the fragrance so much sought after in the queen of flowers. This list—in which the first thirty mentioned are those which, in my opinion, are superior in this respect—may be useful for the guidance of persons intending to improve or enlarge their collections. I have said nothing about the Moss, Provence, Gallica, or Tea-scented varieties, which are all more or less highly perfumed. Amongst the Tea-scented kinds, Maréchal Niel is decidedly the sweetest and most powerfully scented of all. My list embraces Hybrid Perpetuals only.

La France	Maurice Bernardin
Marie Baumann	Exposition de Brie
Alfred Colomb	Velours Pourpre
Sénateur Favre	Duke of Wellington
Monsieur Woolfield	Madame Victor Verdier
Louise Van Houtte	Le Rhone
Bessie Johnson	Leopold Hausberg
Souvenir de Julie Gonod	Madame Moreau
Madame Thérèse Levet	Mdlle. Julie Peread
Baroness Louise Uxkull	Jules Margottin
Duchess of Edinburgh	Duc de Rohan
Alexander Dickson	Mdlle. Marie Rady
Sénateur Vaisse	Princess M. of Cambridge
Duke of Edinburgh	Miss Laing
Pierre Notting	Madame Knorr

The above thirty varieties may be depended on as being amongst the most highly perfumed Hybrid Perpetual Roses in cultivation; the following are, however, little inferior:—

Madame de St. Pulgent	Dupuy Jamain
Duchesse d'Orleans	Baronne Haussmann
Souvenir de Spa	Gabriel de Peyrouny
Vicomte Vigier	Madame Clotilde Roland
Prince Humbert	Mdlle. Marguerite Dombrain
Abbé Girandier	Claude Levet
Madame Auguste Verdier	Felix Généro
Ferdinand de Lesseps	Anna Alexieff
Fisher Holmes	Alpaide de Rotalier
Annie Wood	Marguerite St. Amand
Charles Lefebvre	Semiramis
Madame Charles Wood	Madame Boll
Jean Cherpin (Bennett)	Prince Camille de Rohan
Emilie Hausberg	Madame Rousset
Cheshunt Hybrid	Gloire de Santenay
Camille Bernardin	Madame George Paul
Lord Clyde	Adolphe Brogniart
Captain Christy	Souvenir du Général Douai
Madame Marie Finger	Elie Morel
Madame Derreux Douville	Edouard Morren
Xavier Olibo	Beauty of Waltham
Duchesse de Caylus	
Leopold Premier	

Scentless Roses.—During the last twenty years a quantity of new Roses has been introduced into England from the Continent, most of them of the class known as Hybrid Perpetuals, and all remarkable for their sweet fragrance. Since 1869, generally known as Castellane's year, a change has taken place, and many of the Roses introduced since that time are entirely without fragrance. A large number of the scentless varieties, a list of which is subjoined, will be found amongst the finest exhibition Roses of the present day. Although, as regards form and colour, many of these are perfect, the entire absence of perfume is a great drawback, and the only way to get over the difficulty, when using them in a bouquet, is to place some highly-scented varieties amongst them. In giving this list of scentless Roses I may state that they have all been introduced during the last six years except one, viz., John Hopper, which came out about ten years ago; this Rose is scented, but so slightly as to be scarcely perceptible:—

Marquis de Castellane	Henri Ledechaux
Baronne de Rothschild	Marguerite Appert
Etienne Levet	Princess Beatrice
Comtesse d'Oxford	Etienne Dubois
Lyonnaise (Lacharme)	Madame Victor Verne
President Thiers	Mdlle. Eugénie Verdier
Princess Christian	Marquise de Chambon
Clémence Raoux	Princess Louise Victoria

H. T.

Planting Roses.—Those who wish to plant Roses, or add new varieties to their collections should lose no time in selecting the kinds which they require. In planting, use some good loam and rotten manure that have been turned over two or three times and thoroughly mixed, and also add one-fourth of road grit. See to Briers that have been budded this summer, loosen the ties if too tight, remove all suckers, shorten back any very strong growths that occur in trained Roses, so as to keep them symmetrical, and tie up growths from this season's buds, so as to save them from being damaged by wind.—G.

Autumn Roses.—At no season of the year are Roses more beautiful than in the autumn; in fact, the blooms of several varieties surpass in quality, if not in quantity, those of June and July, and notably those of such light kinds as Souvenir de la Malmaison and Acidalie, and of dark sorts, General Washington, the summer flowers of which are frequently imperfect. Many others among Hybrid Perpetuals, Teas, and Chinas also produce better blooms in autumn than in summer. The majority of our Roses are on their own roots, in beds or raised banks, on which the longest shoots of each year are pegged down, most of the old wood being cut out in winter. By this means we get an unlimited amount of bloom. There is one advantage in cutting the plants in early, and that is, they start into vigorous growth immediately they are relieved from their burden of flowers, and the lateral shoots of all the really perpetual flowerers yield a second crop in the autumn—in many instances, as I have said, superior to the first. Where Rose-buds are in request at this season, that beautiful variety Celine Forestier should be largely grown; with us it continues to produce its blossoms until the Tea Roses under glass are ready to furnish a supply.—J. G.

To Make Asphalte Walks. — For kitchen gardens, courts, or yards where a clean, smooth, durable path is an object, there is hardly anything better than asphalte when properly laid down. Weeds never grow upon it, which is a consideration; and every shower of rain washes it clean; it has no offensive smell after it has been down for a few weeks, and it will last under the usual traffic for many years. First of all, the walks must be set out and got in readiness, and then the ashes—usually plentiful about a garden—must be sifted. A 1-in. sieve or screen must be used. If the ashes be put through a wider mesh than this, they are too lumpy, and do not bind well; and if through a less, they contain too much small, and the cake is too soft and yielding. They should be thrown into a circular flat heap about 2 ft. deep when sifted, and the tar should be got and emptied over them at once—about as much as will soak them the first time without draining away to waste, which is a matter of judgment at the time. It is better to give too much, however, than too little, as what tar runs through can be ladled up and poured on again until the ashes absorb it all, which they take a little time to do. As soon as the tar has been emptied on, however, the heap must be turned at once, and turned again, mixing the wet with the dry ashes as the work proceeds, so as to soak up the tar as much as possible; and when finished the heaps should be thrown into a conical shape, and left to soak for about a week, when the ashes will appear much drier than they were when turned, in consequence of the tar soaking into the cinders more completely. This is the reason of applying the tar twice. If the whole be put on at one time, the half of it will run off, and after the ashes have been put on the walk they will dry and break up like a macadamised road in dry weather. The first dose of tar saturates the cinders, and the second makes them sticky. At the end of a week the second dose must be given, the heap turned as before, and again left for several days. The drainings may be poured back on the heap again, but if the tar persist in draining through, it is better to let it run away or use it on another heap, for the ashes must not be puddly or dripping with the tar, but, as we have said before, sticky only and no more, otherwise the walk will not set hard. When it is seen that the material is in this condition, wheel it off on to the walk and spread it about 4 in. deep, and level it as it is put on with the back of a rake, leaving an even surface, and taking care that the walk is slightly rounded towards the centre, in order to throw the water off to the sides. As soon as all has been put on, roll it with a wet roller two or three times, and keep the roller clean with a besom as it goes along. After this sprinkle the surface with gravel or spar put through ½-in. sieve so thickly as just to hide the asphalte, and roll again for three or four hours till it is quite firm, and continue the rolling for an hour or two every morning when it is cool, for three or four days. If the work has been done with ordinary care, the walk is fit for traffic as soon as it is finished, and is perfectly clean to the feet. If the gravel have been put on thick enough, it makes a clean, dry surface at once, and keeps its colour perfectly. Should more be sprinkled on than will roll in to stick, it can be easily swept off afterwards when the asphalte has fairly set. A walk finished in this way—and it must be sprinkled with something—has just the appearance of a gravel walk smoothly rolled. As regards edgings for asphalte walks, it is only necessary to plant the edgings after the asphalte has been put down and is set, and as the asphalte can be put down and rolled with the utmost exactness, the edgings can be planted close up to it.

A Rain-water Supply.—Valuable as may be a constant supply of rain-water, especially in a district where the earth water is scarce, there is one feature that would be to me very objectionable, and that is, the large quantity of dirt that must of necessity accumulate in underground tanks, in consequence of the frequent washings to which the house roofs are subjected. The evil is of small moment perhaps when rain is frequent, as is often the case in the autumn and winter, but after a long spell of drought we find that the house roofs become covered with dust, smoke, blacks, birds' excrement, and other elements of dirt, all of which the first rainfall washes into the tank, where in course of time it settles to the bottom, and forms a sediment of filth that must eventually contaminate the whole of the water, and be the greatest evil when the water gets low. It is impossible to avoid this result entirely, and it is equally impossible to filter the water in its passage in the tank, because rains are often so heavy that the attempt to filter them would doubtless result in a flood. One thing, however, could be done, and that is, an arrangement made by which the water falling on the roof during the first storm that came after a long drought, or the first portion of a storm, might be diverted into a drain or some other course until the roof was clean, and then it might be permitted to flow into the tank. If it is found needful to clean out an ordinary water butt or open tank every few months how needful must it be to do the same for a large tank that has been receiving water for several years. —A. D.

Substitute for Turf. — Lately, while walking through a suburb of a large town, I came upon a front garden so bright and fresh in comparison with others that it appeared like an oasis in the desert. The materials employed were inexpensive; indeed, much less so than those commonly used. I can understand and appreciate the love which the town dweller feels for a bit of green turf, but where the houses are crowded together it is difficult to keep turf in good condition. The substitute for it which I saw in this case, and which I can strongly recommend, was the well-known Creeping Jenny (Lysimachia nummularia). This grows wild almost all over the country. It thrives in Grass fields, creeping along close to the ground, and

only making its presence known by its bright yellow flowers when the grass is short or thin. It is equally at home on dry, sandy banks, or by the side of watercourses, with its creeping stems at times under the stream. It makes a close-growing carpet with but little attention, even in the smoky, murky atmosphere of large towns, and in such places for this purpose it is well worth more attention than it receives. In the case to which I am now referring it formed a green circular plot in front of the dwelling. In the centre of it was placed a good, bold mass of the old red Fuchsia gracilis, and the effect was quite unique. The other plants in the garden were in keeping therewith, as was also the house, which was draped with Veitch's Virginia Creeper, an exceedingly handsome kind, which clings to the wall with a tenacity that scarcely anything short of actual violence can disturb.—E. H.

House and Window Gardening.

Harvest Decorations.—At this season, when harvest services are being held, a hint or two on church decoration may prove interesting to some of the readers of GARDENING who are, perchance, about to lend their aid in such work. As a rule, much more attention is paid to the Easter and Christmas church decorations than to those employed at this season, and this I consider a mistake, as a far finer effect can be produced with the materials now available than at either of the above-named seasons. Hothouse flowers can be obtained, it is true, during even the coldest weather, and lovely bouquets and wreaths are made therewith at Christmas, but as fine effects can be produced at this season with golden Corn, fruit, and tinted foliage as it is possible to imagine. Where Corn is employed for plume-shaped decorations, Oats are by far the most graceful; but where sharp outlines are required I prefer Barley to Wheat, as it has a lighter effect. Letters for texts can be made of Barley or Wheat on a scarlet foundation. The prettiest plant for intermixing with Corn are trails of the bright-tinted Virginian Creeper, just now in perfection; for twining up pillars and round capitals no more charming plant can be found. If the sprays be light and liable to break they should be supported by means of a slight wire fastened at intervals along the stem. It is best, if possible, to place the end of the stem in a pot or some such receptacle filled with wet sand, as otherwise the leaves will droop and the whole effect will be spoiled. For smaller decorations tinted Vine leaves and odds and ends of tinted foliage too numerous to name obtained from hedgerows will be found most useful. In the way of coloured berries none will be found more desirable than those of the Mountain Ash, and I have used Hips and Haws before now with happy results. There are, however, many berry-bearing plants in perfection just at this season, and I have named the above merely as examples. With regard to flowers, we have at present large numbers, from amongst which may be selected the following, viz., Gladioli, Asters, Lilies, Hydrangeas, Roses, Dahlias, and Fuchsias. These are best suited for bold decorations, such as large crosses and devices for blank spaces on walls, and wreaths for pillars and window-sills, smaller varieties being best adapted for the decoration of the pulpit, reading-desk, or font. Fruit should always occupy a prominent place amongst harvest decorations; it looks well intermingled with flowers and foliage round the chancel or at the base of the pulpit. Amongst the smaller flowers some blooms of Cornflower should be obtained, if possible, as they are in keeping with the Oats and Barley.—A. H.

Cats in Gardens.—The following report of a case decided lately at the Greenwich Police-court may be of interest to your readers, and the magistrate's significant remarks will be, I think, instructive:—At the Greenwich Police-court, on Wednesday, Walter M'Laren Henry, of 1, St. Helen's Villas, Stanstead Road, Forest Hill, was charged on summons, by Mr. W. H. Sanders, with unlawfully placing poisoned meat for the purpose of destroying a cat. Mr. W. E. Benson, living two doors from the defendant, said that on Friday, August 20, he found his cat dead in the garden, having evidently suffered great pain. He wrote to the defendant, and he acknowledged having laid poisoned meat about to destroy cats, which were a nuisance to him, and destroyed his garden. A person living near had also lost a cat. For the defence it was urged by the defendant's solicitor that the cat was not a "domestic animal" within the meaning of the Act of Parliament when allowed to stray by night. Mr. Balguy remarked that Mr. Henry had brought it all upon himself by his excessive candour. He ordered the defendant to pay the cost of the summons.—ILLAWARRA.

FRUIT.

Wall Fruit Trees.—The season is now at hand when tree planting may be successfully carried out, and also when, owing to the trees being leafless, the walls may receive that attention of which they frequently stand in need. One of the first considerations should be a smooth even surface, free from nail holes or inequalities of any kind, as where these exist insect pests find shelter in them in winter, and are ready to recommence their attacks in spring. Old walls should be plastered and receive a good coating of whitewash, as it not only looks clean and sweet, but white has been proved by direct experiment to be the best ground colour on which to train the trees. I need scarcely remark that any trees infested with scale should be well scrubbed, taking care to save the buds as much as possible, and then painted with some strong insecticide. As regards the manner of training, I believe that the wiring system has many advantages, if the wires be properly fixed, so that the wood is kept close to the walls; but when the wires are stretched horizontally in any considerable lengths the strong branches draw them away from the walls, and consequently the benefit arising from the latter is lost. As regards borders, I am of opinion that most of our wall trees will grow well in any soil that produces good crops of vegetables provided the border be deeply cultivated at first and confined to the roots of the trees afterwards; or, if not the whole border, a wide alley, at least 4 ft. from the wall, should remain undisturbed and mulched during summer, and the remainder should only be employed for shallow rooting choice vegetables or salads. More attention should also be paid to the rotation of wall trees than that subject ordinarily receives, for if Peach trees have occupied a south wall for twenty or thirty years it is almost a waste of time and trees to suppose that merely trenching the border will supply their wants. No; they must have fresh soil, but in many cases the best course would be, as Peach culture under glass extends, to devote a larger amount of south aspects to the choicer kinds of winter Pears, such as Easter Beurré, Glou Morceau, Beurré Rance, &c. We have hitherto given winter fruits only a secondary position where they naturally only attain second-rate quality. East and west walls will bring to perfection most of our ordinary mid-season Pears, Plums, Cherries, &c., and north walls may be profitably occupied with Morellos and other Cherries, Currants, and dessert Gooseberries; but the south aspects should be devoted to the earliest Cherries, a selection of Peaches, Nectarines, and Apricots, and a choice collection of winter Pears. Space is too valuable to allow them to be trained horizontally; therefore, some of the many modifications of the upright cordon will be found an improvement, producing, as it does, speedier and better results.—R. J. G.

Male and Female Blooms of a Melon.

Late Plums.—Amongst Plums now in season I find Coe's Golden Drop and Reine Claude de Bavay to be the best amongst light-coloured kinds, and Coe's Late Red and Ickworth Impératrice the best amongst dark sorts. These form useful additions to the dessert where great variety is required late in the autumn. Many late Plums are only valuable on account of their late keeping qualities; but Coe's Golden Drop is one of the finest flavoured and best of all dessert Plums when fully matured.—J. G.

The Ribston Pippin Apple on Walls.—The finest and most highly-coloured fruits of this that I have seen were on walls in a fine kitchen garden in Pembrokeshire. Where this fruit is a favourite, as it so very often is, it would be worth while, even in the most favoured districts, to grow a few trees on walls, if only for the sake of having fruit of a somewhat different character from that on standard, espalier, or other trees.—V.

Male and Female Blooms of Melons.—We have often been asked by novices in gardening how the male and female blossoms of Cucumbers, Vegetable Marrows, and Melons can be defined. The annexed engraving answers these questions, perhaps, better than we could by the pen. The large bloom on the right with a embryo fruit at its base, is the female, which bears the fruit, and the small bloom on the left is the male, from which pollen must be conveyed to the female in order to insure fructification. During summer this work is performed by bees or other insects, but in the dull months of the year it must be done by the cultivator when both blooms are fully expanded. The male should be plucked off, the calyx split open by tearing apart the petals, and then, holding it over the female flower, tap it with the thumb-nail so as to shake the pollen into the female blossom, or the whole of the petals may be removed, the remaining portion being gently inserted into the female flower. A camel's-hair brush may also be used if prefered. First, gently insert it in the male blossom in order that the pollen may stick to the brush, then into the female blossom.

Transplanting Fruit Trees.—When the trees to be removed are close at hand, so that the roots need not be long exposed to the air, I consider October to be the most favourable month of the year for transplanting fruit trees, as the soil being warm, fresh roots are at once emitted, and the trees start into growth in spring without a check; but where they have to undergo a long journey by rail, it is better to wait until the leaves are off. Last season we removed several Plums, &c., that had been temporarily planted on vacant spaces, and the growth which they have made this year is unusually satisfactory. In preparing sites for stone fruits I would warn the inexperienced against an error commonly committed, viz., filling the trench half full o manure, with the view of giving the trees a good start; the result of this is gross, watery shoots, which, necessitating so much knife-work, eventually bring on canker and other evils, from which trees planted in sound loam generally escape.—J. G. H.

Cherries on North Walls.—It is generally supposed that a north aspect is only suited for the Morello Cherry, but this will be found to be a mistake, for my experience is that the May Duke has grown successfully upon a north wall. A really good ripe May Duke will fairly

bear comparison with any fruit, and no other of which I am aware will stand carriage so well without injury. It is a fruit for every one, and a tree for every vacant spot of wall of a few feet, be it north, west, south, or east; indeed, if a few May Duke Cherry trees be planted in each of these aspects, so much longer will be the season of fruit. It must be regretted also that in many gardens every variety of Cherry but the Morello is planted on one wall only. The extraordinary fine crop I have had this year on a north wall has induced me to advise others to give a part of "the Morello wall" to May Duke and Late Duke Cherries, for I began to gather the Dukes in June, and only finished last week, and the last batch might have remained a week or two longer on the trees. To grow May Dukes on north aspects successfully requires all the pruning to be completed in summer; winter pruning means gumming, and I find that as the soil keeps cold and wet, a good coating of old brick and lime rubble is a great restorative, and will well repay the labour and expense attending it. I would caution your readers against the mistake of planting any varieties of the Heart Cherry on north walls, for they will not succeed.—J. T., *Shrewsbury*.

GLASSHOUSES AND FRAMES.

Lobelias from Seed.—I cannot quite agree with "Saxon Deyne" as to there being no advantage gained by sowing Lobelias in the autumn. With plenty of heat they may be got into good condition if sown in March, but having this year tried sowing some at that time in an unheated greenhouse allow me to give my experience. The seed used was compacta Emperor William. It was sown in the middle of March, but did not come up for three weeks. The plants were just fit to handle at the end of April. They were put out in the ground in the second week in June, and began to bloom in the end of July, and are now in good bloom, owing to being backward and very small. When removing from the seed-pan three and four roots were put into one thumb-pot. These were plunged into Cocoa fibre, and are now good large clumps of bloom, but a little straggling. I am trying autumn sowing this year; have now some more forward than those put out in ground in June; am just about to prick them out into pans or boxes; shall pinch them back once or twice, and then hope to have good, bushy plants in blossom next May—a gain of two months' bloom, some slight advantage, I take it, besides having a more compact growth. May I venture to suggest to some of your correspondents that the information so kindly given and so extremely valuable would be much more so to many readers if they would kindly remember some of us—the readers—although dear lovers of our gardens and our flowers, have not always a supply of heat at hand, and consequently have to act accordingly.—T. C.

Large-flowered Jasmine in Autumn.—This is one of the most useful of indoor plants at this season. Its pure white, sweetly-scented flowers are invaluable in a cut state, and either in pots or planted out it flowers freely if liberally treated. It is now being largely grown by London florists for furnishing cut blooms during autumn and winter, and it is highly valued in the market. Plants of it, which are best obtained by means of layers, grow well in rich sandy loam and leaf-mould, or well-rotted manure, intermixed with a few pieces of peat to keep the compost open. It is called Jasminum grandiflorum.—C.

Wintering Pelargoniums.—As Pelargoniums still occupy a prominent place in the flower garden in summer, the question of how to store the requisite number during winter is an important one. There are still many who continue the old-fashioned custom of striking the cuttings in the open border, lifting them when well rooted and potting them in single pots, a plan which answers well where labour is abundant and space equally so, but I find that putting the cuttings into boxes about 4 in. deep, 2 ft. long by 1 ft. 3 in. wide, being space enough for about seventy-five cuttings, reduces the space required for wintering such material considerably compared with what is possible when the plants are potted off singly. There is, however, no question as to each plant in a single pot being the best for producing good-shaped plants, but when space is limited this cannot be done.—J. G.

The Scarborough Lily (Vallota purpurea).—This is one of the best of window plants and one of the most easily cultivated. If bulbs be procured now and kept gently growing on through the winter in any glasshouse or window, keeping them moderately watered and in a light position, they will, by next autumn, have made fine large flowering roots; then keep them rather dry for a time, but not sufficiently so to in any way injure the foliage, and fine large trusses of exquisite scarlet flowers will be the result. They will succeed well in 5-in. or 6-in. pots, and they do not require frequent repotting. Established plants which have done flowering should, during the next three months, be kept somewhat drier at the roots, yet, as they are an evergreen species, the soil must not be allowed to become completely dried up, or the leaves will flag, which will have the effect of causing them to turn yellow and fall off before their time, which would not only prevent their fully blooming the ensuing summer, but would also considerably reduce the strength and size of the bulbs. For single bulbs 5-in. or 6-in. pots are most suitable, or a 9-in. pot will hold four or five full-sized bulbs of Vallota that will continue in bloom for a month. Vallotas are readily propagated, the

Scarborough Lily (Vallota purpurea).

bulbs increasing quickly through the production of numerous offsets, which are formed every year at the base of the old bulbs; these, when about the size of large Peas, will have made two small leaves each and a small root or two. They should be placed eight or ten together in 6-in. pots, well drained in ordinary sandy loam, in which they may remain for a year or eighteen months; like the flowering bulbs, they must not receive so much water during the winter as in the growing season.

Wintering Plants of various Kinds.—Those plants that have stood in pits where the lights can be taken off in the daytime should be kept under such conditions so long as they are safe from frost, for cool treatment of this description is best calculated to bring about a desirable cessation from growth and to aid in ripening the wood. In the southern parts of the kingdom and on the coast, where frosty nights do not usually occur until later, it is not requisite to take the plants in so soon as in less favoured localities; this, with the appearance of the weather, will point to the necessary time for getting everything where it will be secure for the winter. On fine autumns, where a few loose lights could be placed over them to ward off heavy rains, I have kept Heaths out till October was far advanced, and where there is the means of giving them this slight protection they are better out, especially where Heaths have not a house to themselves, but have to be accommodated along with other plants that need to be kept a little closer. In getting plants into their winter quarters it is necessary to proceed systematically, placing the different kinds in the positions best suited to them, such subjects, for instance, as Azaleas and Epacrises with any other hard-wooded greenhouse plants that form their bloom-buds in the autumn, and whose shoots are quite or all but dormant through the winter, although in common with all others of a kindred character, are benefited by a situation in which they will receive a full volume of light; yet where the entire stock cannot be so accommodated they will do standing under worse conditions in this respect than any plants whose shoots keep on growing slowly throughout the winter, and the flower-bud development of which takes place wholly during the winter months. Heaths, with the exception of a few varieties, make no shoot growth in the winter; still it is during this time that almost the whole of the flower formation is going on, and on this account they cannot be kept too near the glass in the best house that can be afforded them. Pelargoniums, though totally different from the last named subjects, making as they do the greater portion of their shoots in the winter and spring, need to be under the full influence of light. Kalosanthes (Crassulas), now not near so much cultivated for general decorative purposes as they deserve to be, although they make comparatively little shoot extension in the winter, yet usually bloom much more profusely when placed where their heads will be within a few inches of the glass from this time until spring. Late-flowering Camellias and any of the Citrus family will do now for some months with comparatively little light. I particularise these things with a view to its being of some use to amateurs and beginners in plant cultivation, who will find it much more convenient and conducive to the well-being of their plants to consider the respective requirements of the different subjects they have to deal with, and thus at the present time put each in the most suitable winter quarters, so that there will be no necessity to again upset the houses by making any alterations in the positions the various plants occupy. In most places, large or small, such a number of plants have to be wintered as makes it necessary to place a portion under less favourable conditions than they would be subjected to, were there alike room to treat all in the most desirable way. Yet much may be done with a mixed collection of plants to bring them successfully through the winter when the requirements of each are considered; the reverse of this is often observable when at the time of housing they are crammed in anyhow by mere haphazard. Another matter essentially necessary at the time of getting the plants in is to see that all are free from insects, such as aphides, thrips, and red spider, for though these will not for some months increase nearly so fast as during the spring and summer, yet affected plants communicate them to others that stand near, on which they remain in a more or less dormant state, ready to increase in vast numbers at the return of the growing season, when the softer condition of the plants makes it much more difficult to deal with them, entailing a correspondingly greater amount of labour.—H.

HOW TO GROW ACHIMENES.

As this is the time when these beautiful summer-flowering plants are dying down, it affords a good opportunity of giving some instructions as to their culture, as to those who already possess a supply of bulbs the present may be termed the starting-point for another year. Those who do not possess bulbs may wait till March, and then follow the directions given below.

The value of Achimenes to those having only a limited amount of plant room, and who are nevertheless desirous of making a rich floral display during the summer months is, that they die down and require no care in the winter beyond being stowed safely away out of reach of frost, wet, or rats and mice, which feast on the tubers. Another merit of Achimenes is, that they require no expensive stove-house or similar structure in which to grow them, as they will do equally well, indeed better, in any hotbed, pit, or frame, such as is usually made up for Cucumbers, Melons, &c.; while later on they may be grown without artificial heat if advantage be taken of sunshiny days to shut them up early and secure the requisite warmth in that way.

In Baskets.—Beautiful as Achimenes are when grown in pots in window recesses in rooms, or for the embellishment of greenhouses, they

are even more so when suspended in baskets, for which work their habit renders them peculiarly adapted, as they droop over in the most graceful manner possible, and show off the flowers with which they are laden to the greatest advantage. In pots they require stakes to support them, but in baskets few are necessary, as they generally present a more effective appearance trailing naturally over the sides; and the less formal they grow the better they look. The baskets in which I grow them are basin-shaped, made of galvanised iron wire run round a frame made of the same, a trifle larger in size, and bound tightly together, which any handy man can do. These are then lined with rough Moss and filled up with the same kind of soil as recommended for the pots, and the plants afterwards ranged regularly around the sides by making holes with the finger between the wires in which to insert the roots, after which they should be hung up in any warm house and kept well watered and syringed till they begin to show bloom. By starting some in March and others at intervals of a month or so till the end of June or middle of July, a constant succession may be maintained till quite late in the autumn and far on through the winter, by adding A. picta to the collection. Whether grown in baskets or pots, it is a great saving of space to start a sufficient quantity of each kind in separate pans or pots, and afterwards to divide and transfer them to the positions in which they are intended to flower.

In Pots.—A hundred tubers will be sufficient for ten 6-in. pots, which are the best and most useful sizes for room decoration or ordinary purposes; but if larger be required, a few more plants will be necessary to fill them. They may be started into growth in any small pot or pan in finely-sifted leaf-soil and sand, in which they should be allowed to remain till they get 1 in. or so high, when they may be taken out and carefully separated for potting or putting in baskets. Owing to the great quantity of water they require when growing, the pots must be well drained, which should be done by filling them up to a third of their depth. The next operation is to cover the potsherds with a few half-decomposed leaves, rough fibry peat, Moss, or any similar material, in order to prevent the soil blocking them up.

Soil and Potting.—The best compost for Achimenes is a mixture of rough fibry peat and loam or leaf-soil, and the latter in the proportion of one of loam to two of peat or rotten leaves, in either of which the plants greatly delight, adding just sufficient sand to keep all open and porous. In potting, they should be placed at equal distances apart and the roots covered loosely, but not in sufficient quantity to fill the pot, as they make better progress if afforded a top-dressing later on when they get into growth and begin to form fibres around their stems, a little fresh soil at that period becoming of the greatest assistance to them. After the potting has taken place, they should again be placed where they can enjoy a warm temperature ranging anywhere between 55° and 65°, with plenty of moisture in the atmosphere, and in such a position as to be near the glass exposed to the light to keep them from drawing. The degree of heat above-named is the minimum they will endure or ought to have early in spring, but if more can be afforded with a proportionate amount of humidity, they will grow all the faster and come earlier into bloom. Although Achimenes require a moderate amount of heat and a moist atmosphere while growing, they will endure any ordinary greenhouse temperature during the summer, and if kept well watered they will last a long time in perfection.

Shading, &c.—Although Achimenes will endure all the sun we get up to the end of April, they will not do so afterwards, as they are naturally shade-loving plants; and it is therefore necessary to throw a mat over them to screen them for an hour or two in the hottest part of the day during the height of summer, or whenever the sun's rays are full upon the glass. At that season any cold frame, having a few leaves in which to plunge them, or a firm bed of ashes on which to set them, answers admirably, as in such a position they can be treated more in accordance with their requirements than they could be elsewhere among other plants. A heavy syringing overhead both morning and afternoon, or a gentle bedewing through the rose of a watering-pot during dry weather, so as to thoroughly moisten their foliage and the material in which they are plunged or on which they are placed, is the course of treatment to pursue while they are growing; and to assist them in their development the house should be closed about three o'clock in the day, in order to take advantage of sun-heat.

Staking.—The necessary staking and tying should be done before they become too advanced, or the blooms get damaged during the operation, besides which their fragile stems are not sufficiently stiff and strong to remain erect after they have attained a height of 6 in. or more. The neatest and best stakes are the long, twiggy prunings from Privet hedges or bushes, which should be cut at once and tied tightly up in bundles and laid by till required. They then become hard and almost as stiff as wire, and, being nearly the same colour as the stems of the Achimenes, they are scarcely observable, thereby removing to a great extent the objectionable appearance which stakes among pot plants generally present, and as the plants require one to each main stem deal sticks would be much too obtrusive, and quite spoil their attraction.

VEGETABLES.

Celery Culture.—I grow Celery as a general crop, and it may interest some of your readers to know how I produce a superior Celery. I sow for general crop in the last week of March, sowing the seed in a box or pan in a gentle heat. I transplant the seedlings when strong enough on a prepared bed or old manure heap 3 in. apart, taking care to give plenty of protection from slight frosts and cutting winds. They grow and get hardened off until planting-out time, which is generally about the second week in July. To bring Celery to perfection it must be grown as rapidly as possible, and on no account should the plants be allowed to get starved or checked. I generally plant in single rows, 3 ft. apart, in trenches 1 ft. deep, with several inches of rotten manure in the bottom, planting the plants 6 in. apart in the row. I never on any account earth up Celery until it gets well established, nor when the plants and soil are wet. When earthing up great care must be taken to prevent the soil getting between the leaves. Some tie it up previous to earthing, which answers very well. Last year we were troubled with the maggot, and I have tried several plans of stopping its ravages. I found nothing to equal dry soot dusted well in amongst the plants every night and morning whilst the foliage was wet.—Kirkton.

Group of Achimenes.

Trenching Vegetable Ground.—Deep stirring of the soil is one of the most important points in vegetable culture. There is no soil that cannot be improved by it, but its effect will be most noticeable on cold, heavy clays. In all such soils there is a vast mine of fertility locked up that only requires to be judiciously worked to have a marked effect upon the crop. During autumn and winter every half-hour that can be spared should be devoted to this work. Cleanliness and surface-culture of the soil are to a certain degree effective in the development of plants, but without deep stirring the land will not produce to the full extent of its capability. Moisture is one of the greatest essentials in the cultivation of succulent vegetables; and probably if our springs and summers were universally hot and dry, the importance of deeper culture, as one means of attracting and retaining moisture in the land, would be more generally recognised. At present, when a dry, hot summer comes, and plants are perishing from drought, it is found convenient to ease our minds by throwing all the blame of indifferent crops upon the weather instead of trying to ascertain whether the system of culture adopted was the most suitable to our climate. In trenching land where the subsoil is very inferior, probably in extreme cases some injury may have resulted from bringing up too much of the crude, inert soil from below to the surface. All clays are retentive of moisture in wet seasons, but they often crack and part with it too rapidly in dry, hot summers. Now all this may in a great measure be improved or counteracted by deep culture. The drainage in wet seasons would be more effectual, and in dry weather the advantages of deep culture would be twofold—there would be greater facilities for the plants striking their roots downwards, and the loose subsoil would encourage the ascent of moisture from the water bed below on the principle of capillary attraction. On wet lands, wherever artificial drainage may be necessary, it should always precede all other measures for ameliorating their condition. A test hole 3 ft. or so deep will readily tell if artificial drainage be necessary. If water stands in the bottom of the hole for any length of time at any season of the year, the drainage is certainly imperfect. In dealing with a bad subsoil, it will be better to try and improve it without bringing any to the surface. This can most effectually be done by removing the top spit, as in bastard trenching, and then digging or forking into the bottom any fertilising substance, such as manure, ashes, road scrapings, or burnt earth—anything, in short, that will tend to open up and disintegrate the crude mass. In this way a steady improvement will go on; air and water will percolate through it more readily, rendering its mineral constituents more soluble and suitable for plant food, and in the course of time portions of it may be brought to the surface and still further improved by exposure to the frosts of winter.—E. H.

Johnstone's St. Martin's Rhubarb.—This is a very fine variety, strong in growth and excellent in flavour, not being nearly so acid as some varieties. I would strongly recommend those who contemplate planting Rhubarb during the ensuing season to include this as a standard variety—good for all purposes.—J. G.

Cabbages for very Early Use.—With spring Cabbages, earliness and tenderness, the result of rapid, unchecked growth, is preferable to mere size. In fact, few people care about a very large Cabbage at any time, as, according to my experience, size is generally obtained at the expense of delicate flavour. Now everybody has warm corners about their premises somewhere, or can easily extemporise some shelter. Into one of these warm spots dibble a quantity of Atkins' Matchless Cabbage, 6 in. or 8 in. apart each way; have as much depth of soil as possible, keep the surface freely stirred as often as it happens to be dry, and after Christmas, just when they appear to be folding up their leaves to form a heart, give one or two good soakings of liquid manure or house sewage.

This crop, of course, is only intended for the first cutting, and as fast as they are cut the stalks should be pulled up, and the ground prepared for some other crop that will appreciate the warm position better than the Cabbage will when the hot days in spring arrive. A very large number of dishes of sweet early Cabbages may be obtained from a small space in this way. There is yet time to plant out a batch, although it would have been better done last month.—E. H.

Blanching Late Celery with Spent Tan.—The soil of my kitchen garden is very strong and retentive, and I have great difficulty in keeping late Celery from rotting during the winter months. Of late years I have used old spent tan principally for earthing it up, and find it to be one of the best materials yet tried, both for keeping the plants free from slugs and from severe frosts. During winter, when there is much rain or snow falling, I have wooden coverings placed above the plants to throw the water off the rows; these coverings are formed of old slabs or planks of little value, and are nailed together in the form of a span roof, and sufficient space must be left below the covering to give the plants plenty of air. To obviate blanching the plants too much near the surface, these wooden coverings must only be kept on during very severe frosts, or heavy falls of rain or snow.—W. T. W.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

October 4.—Potting up Carnations and Pinks; also Pelargoniums from flower borders, likewise old plants of Centaurea—potting hard and watered well first time; putting Purple King Verbenas into cold frame; placing all Strawberry plants in pits under cover; inserting Calceolaria cuttings; planting Hyacinths and Tulips in open borders; planting Peach trees; pricking out frames of Cauliflower plants; tying up Endive; gathering Beurré d'Aremberg and Winter Nelis Pears, and a few of Knight's Monarch; making border ready for Cauliflowers; rearranging drainage, and top-dressing Roses in pots after removing as much as possible of the old soil; giving bearing Cucumbers a top-dressing of loam and manure; bearing borders from dead or bad-looking stems of herbaceous plants; putting lights over scented-leaved Pelargoniums, Violets, and a bed of Mignonette.

Oct. 5.—Potting up plants of Echeveria glauca, and putting them in the greenhouse; placing a few of the most forward Cinerarias in heat; planting Cabbages for spring 6 in. apart in the rows, so that part can be taken up in spring to make another bed; making up failures among spring Lettuces; planting Cauliflowers under hand-glasses; taking off Chrysanthemum layers.

Oct. 6.—Potting Forget-me-nots, also Schizostylis for winter flowering; taking in Chrysanthemums; taking up some of the most forward Cauliflowers and putting them into a trench for protection; planting Stephanotis in small bricked bin; pricking out a bed of Cabbage plants to remain until spring to be then planted permanently; taking up Beetroot.

Oct. 7.—Plunging Stocks in cold frame; planting Wallflowers in flower-beds, also Aubrietias, Arabis, Pansies, bulbs, Feverfew, and Cerastium; tying Chrysanthemums, also more Bath Cos Lettuce; bending leaves over Cauliflowers ready to cut; beginning to nail wall trees; gathering the last of the Apples, Nonpareils, and the last dish of Plums; roping Onions in wet weather; earthing up July-sown Cabbage.

Oct. 8.—Potting off some herbaceous Calceolarias; re-arranging Odontoglossum house; planting Gooseberries and Currants behind north wall; nailing Currant trees, &c., on north wall; also Gooseberries; cutting Marjoram, and placing it where it will dry; digging vacant ground; pruning Cotoneasters on walls.

Oct. 9.—Sowing Mustard and Cress in boxes under cover; potting second batch of Hyacinths; taking up Lettuces and putting them in pit; taking up all bedding material that is to be saved; planting fruit trees consisting of Peaches, Nectarines, Pears, Apples, Plums, and Cherries.

Flower Garden.

Owing to falling leaves, worm-casts, and decaying flowers it is now difficult to maintain neatness in ornamental grounds, but as no enjoyment can ever be derived from an untidy garden, an effort should be made to do so. The scythe, lawn mower, roller, and broom will need to be kept going daily, and though the ground may not continue long tidy, we shall have the satisfaction of knowing that we have done our best as far as endeavouring to maintain neatness is concerned. Tender plants that are to be preserved for stock another year, and which cannot yet be lifted, ought to be covered up with some light material every night; tiffany, hexagon netting, or Frigi Domo, are all excellent materials for the purpose. The propagation of plants for another year will still require attention; of course all the more tender kinds ought to be in safe quarters, as frost may visit us at any time. Calceolarias and Violas will now strike freely and winter well—indeed best—in a cold frame. Hardy plants may be divided and pricked out on a dry bank. Mentha Pulegium gibraltarica may thus be safely wintered, but if left thick on the ground as it now stands it will succumb to damp, as will also Cerastium tomentosum and C. arvense. Contemplated alterations and improvements may now be carried out. All such works should be taken in hand early in autumn in order that they may be completed before the busy spring time interferes with their further progress. Walk making, turf laying, and levelling, draining, grubbing, and trenching, and shrub and tree planting, are some of the operations that are best and most conveniently done in the autumn and winter.

Auriculas.—If either seedlings or named varieties growing well are in pots that are not considered to be large enough for them to flower in, they had better be potted, although it is getting late in the season for that to be done. Such late-potted plants should, however, have no surface dressing in February. We find slugs very troublesome, and the only way in which they can be destroyed is taking pains to catch them at night by lamplight. Seedlings are now coming up rather freely, and it is necessary to be careful with regard to giving water; just allow sufficient to keep the soil moist. Many keep their plants on a cool bottom during the summer, but this is just the place in which worms are likely to get into the pots. If worms do get in, the best plan is to turn the plants out and search for them. It would be much better for the plants to shake all the soil from their roots than it would be to allow the worms to remain in the pots.

Carnations and Picotees.—No time should now be lost in getting off layers and repotting them. See, too, that slugs are not allowed to prey upon the leaves of those that have been layered in the open ground; the leather-coated grub also eats the leaves greedily, and should be looked for at night. Tree Carnations now require considerable attention; the plants must be removed under glass, and the stems carefully tied to sticks. Those that have not been repotted should be seen to at once. It is easy to err on the side of too large pots. A very large plant can be grown in an 8-in. pot, and such a plant will produce a very large quantity of flowers. When the pots are well filled with roots, and it is seen that the plants lack vigour, weak manure water can be supplied to them—say about once a week.

Hollyhocks.—Seedlings may be planted out in their permanent quarters, but before doing so see that the ground is in good condition. Perhaps there are few plants that can assimilate so much gross food as the Hollyhock, and to have good results from seedlings the ground should be deeply trenched, and have at the same time plenty of rich manure worked into it. When the spikes are exhausted they may be cut over near the ground, and the roots may be lifted at once, or allowed to remain for a few weeks as it may be convenient. The commoner varieties can be planted out close together in a frame, but scarce, choice sorts had better be potted for the convenience of placing them in a warmer house early in January, with the view of obtaining cuttings from them. Until that time they may be kept in a cold frame.

Pansies.—If it is intended to flower any of these in pots no time should be lost in getting them potted into 3-in. ones. Place them in a frame quite close to the glass, and draw the lights off them both day and night, when the weather is favourable, as the heavy dews on calm nights are beneficial to them.

Glasshouses.

Cool Orchids.—Odontoglossums will, as a rule, need to be treated in accordance with the state of growth they are in. Although plants that do not require nor can bear drying at the roots to the extent that many species will, even when their growth is finished, still they are better with their roots in a drier condition than when active growth is going on. Let those that are in full growth have sufficient root moisture, with enough air to keep the atmosphere of the house fresh and sweet; the ventilators, or other places where air is admitted, should be closed on all nights when there is a likelihood of the temperature running low, as although these plants will bear all but being frozen, still no possible good can come from subjecting them to such treatment at any time, and more especially whilst growing. Masdevallias, Epidendrum vitellinum, E. auranticum, E. erubescens, such Lycastes and others as are grown in the Odontoglossum house, will in cases most be benefited by now being kept at the warmest end and supplied with root moisture in accordance with their more or less advanced state of growth. Shading should now, so far as possible, be dispensed with, only running down the blinds when the sun happens to be bright. Where the Odontoglossums are grown in a lean-to house with a north aspect there will be no further need for any shade at all.

Ferns.—In the case of Ferns, as with other cultivated plants, in addition to the vigilance necessary to check the quicker breeding kinds of insects as they make their appearance, such as aphides, it is well from time to time to go over all the occupants of the house to free them from any of the more persistent species like scale, mealy bug, or thrips; and if at the same time all unsightly fronds are removed, and the pots washed clean, it adds much to their appearance. It is through the dormant season now beginning that insects of all kinds can best be got under with a view to reducing the labour necessary to keep them down whilst the plants are in active growth, at which time insect life is also most active.

Filmy Ferns.—To those who have not had any experience in the cultivation of these plants it is necessary to point out that although nearly hardy their nature is such as to render their existence impossible where the atmosphere that surrounds them is not to a considerable extent saturated with moisture; consequently it is useless attempting to grow them in frames along with other plants, as it is needful to keep them all but closed with a view to avoid the drying influence of the external air. They must always be kept moist at the roots, and the bed of coal ashes on which the pots during the summer ought to stand, and in winter be plunged, must likewise be kept moist. The light also needs to be much subdued by tolerably thick shading when the sun comes at all upon the glass, as well as smearing the glass with thin green colouring during the summer months. If grown in a greenhouse with other plants they should occupy the most shady position in the house, placed on the floor enclosed within an ordinary frame or glass case made for the purpose, and also shaded when the weather is such as to require it. Single plants of Todeas, the hardier Trichomanes, and Hymenophyllums, do very well in rooms where little fire is used, especially near windows with a northern aspect, as a matter of course covered with bell-glasses, or in glass cases, and kept moist. So treated, with the little attention which they at all times require, they will go on increasing in size for many years, and are most interesting.

Fruit.

Gathering Fruit.—The harvesting of Apples and Pears now requires daily attention; our rule is to devote a couple of hours every fine afternoon to such work, carefully examining every kind, and gathering only those that part readily from the tree, or that the birds or wasps have attacked, the latter especially being no mean judges, both of quality and maturity; the birds are not such infallible judges, for tomtits will attack all and sundry, if left unmolested, so that the birds must either be destroyed or the fruit must be netted up. Pears have increased in size marvellously during the last three weeks, and the latest kinds are still swelling fast, so no undue haste should be made to gather them; indeed, most of them will need to be left on the trees till there is danger of injury from frost.

Surface Dressing Fruit Trees.—As soon as the fruit is gathered all trees that have borne heavy crops or that seem weak from exhaustion should have the surface soil cleared away from about the roots and replaced with fresh compost, consisting of loam, with a slight proportion of lime scraps and charcoal intermixed, the whole to be made firm about the roots, and then mulched with good stable-yard

manure. If such dressings could be given to free-bearing fruit trees every autumn we should have little cause to complain, either of size or quantity of fruit; this at least is our experience, for on trees that have been regularly dressed we have never yet failed as regards having plenty and fine fruit, and the present unfavourable season is no exception to the rule.

Root Pruning.—This month is the best time to root-prune all trees that require a repression of growth, in order to make them more fruitful. Young trees that have not been planted more than three years had best be lifted entirely; their strong roots should be shortened back, and any that have been injured by digging them out should be cut clean off. The trees should then be replanted in the same soil. Large or older trees may have their roots bared, a trench cut out a few feet from the stem, and all the roots met with in the trench cleanly cut off, after which, re-fill the trench, ramming the soil as firmly as possible, thus causing a certain amount of resistance to be encountered by the roots, which will conduce to the formation of numerous small branching rootlets that are of much more importance than strong nonlateral roots.

New Plantations.—For any new plantations that are to be made, the ground should first be thoroughly drained, and in heavy retentive soils each tree should have a few inches of additional drainage in the form of brickbats, charcoal, and mortar rubbish. Of course, on gravelly or sandy subsoils such drainage is not required, and the trees may be planted level with the ground-line, but on heavy soils a slight elevation or mound is desirable. If the weather be favourable and the ground in good working order, the end of the present month is the best time for planting all the following kinds of fruits, viz., Apples, Apricots, Peaches, Pears, Cherries, Plums, Gooseberries, and Currants. Clear runners off old plantations of Strawberries, lightly point over the surface-soil, and re-dress with good rotten manure. Young plantations should also be kept clear of runners, and those that are fruiting should be carefully protected from heavy rainfalls by means of handlights or frames. The plants of Vicomtesse Héricart de Thury that were planted out after forcing are now fruiting as freely as at the proper Strawberry season.

Lawns, &c.—Grass seeds should be sown at once on bare places or where the sward is thin and poor, choosing dry weather for the work; the quantity sown may be from one to two bushels per acre; in the case of bare places the surface should be broken up about 1 in. deep, adding soil if necessary where the Grass is weak; a dressing of rich soil will be very beneficial; after the seed is sown the surface should be thoroughly bush-harrowed and finally rolled. A dressing of soot, salt, and lime during the month will greatly assist in destroying injurious insects and act as a fertiliser. This work will be especially necessary upon cricket and croquet grounds which have been much used during the season. Where very large spaces have become bare, turfing is the most desirable and expeditious method of dealing with them. The advantage gained by doing this work at the present time is that should we experience a favourable winter the Grass will be stronger and therefore resist wear in a greater degree than if done in the spring; during the operation Grass plots should also be freed of weeds as far as possible.

Shrubbery.

The month of October is an excellent time to commence the rearrangement of shrubs, a work which becomes periodically necessary in consequence of some varieties overgrowing others, over-crowding, losses, and other causes. Care and judgment must be exercised in order that a natural arrangement may be maintained, mixing the various kinds of foliage harmoniously, and having special regard to the different heights the shrubs are likely to attain. Should we be fortunate enough to have fairly dry weather during October and the early part of November, the soil will work very much better than later on in the year; nor are we likely to have very hard frosts during that period. If ordinary care be exercised not to injure the roots, and the shrubs are planted immediately after being taken up, they will in no way suffer from the effects of transplanting. New subjects may be added as required at the same time. Advantage of the season should also be taken to commence preparations where it is intended to form new plantations; the sites for these should be trenched not less than 3 ft. deep, taking care that the bottom of each trench is well broken up. By so doing, great benefit will result to trees and shrubs; it assists drainage and allows the roots to descend freely. Generally, however, the sites for plantations are more or less raised by carting soil upon them, in which case deep trenching is unnecessary. The surface should always be broken up before placing the soil thereon. Where the soil is very poor, manure should be trenched in or mixed with the soil; the manure must not be buried too deeply, 6 in. beneath the surface being quite sufficient, as it should be borne in mind that the benefit is derived from its gradual decay, the soluable portions being carried down by rains to the root in a condition most suitable for its absorption, whilst it maintains the surface in an open and healthy state.

Autumn Crocuses.—The beautiful autumn-flowering Crocus (C. nudiflorus) forms at present quite a gay feature in some nurseries, the beds in which it grows being nearly solid with bulbs, the flowers of which are large, bright purple in colour, and borne well up above the ground. This Crocus likes a rich, sandy soil, and is, I believe, the earliest of the autumn kinds, those which follow being C. speciosus, a lovely free-flowering variety; a little later in the season this is succeeded by C. autumnalis and C. sativus, and still later come the bright and charming little orange-yellow flowers of C. Aucheri simultaneously with those of C. Sieberi, which has purple flowers. The two latter species often continue flowering onwards through the greater part of the winter months when the weather is open and mild. —P.

Violets.—That very fine Violet Victoria Regina is now blooming freely with me, and promises to do so as long as the weather remains open. It is decidedly the best of all the single sorts; it is as much in advance of the Czar as that variety is ahead of Devoniensis, whilst it is inferior to none in colour or perfume. Each flower is about as large as that of the common single Russian, and it is not less floriferous. Grown in a sunny, exposed situation, it does not run too much to leaf, and if the soil be good, it produces a mass of strong crowns that are full of buds. Having just lifted a number of strong plants of this Violet to bloom under glass during the winter, I have taken off all the side shoots and dibbled them thickly into a bed. These will root well during the winter, and, if planted out afresh with more room in the spring, will grow into large, robust plants for the succeeding autumn. Violets of all kinds are now blooming more or less, a circumstance doubtless owing to the heat of the past summer having forced the plants on with more than usual rapidity. The autumn rains, too, by cooling and moistening the soil, have no doubt imparted to it some of the characteristics of spring. Both the double blue and white, double red, and the Neapolitan are blooming in the open ground more or less; also the Russian market Violet.—D.

Planting Hardy Plants.—This is a good time to plant most hardy bulbs and herbaceous plants, and what cannot be planted then should be left till spring, except bulbs, which may be put in any time during the winter or early spring, when the soil is in a fit state. Nearly all herbaceous plants grow and increase fast in ordinarily good soil, and it is not therefore necessary to plant large pieces at first, unless the stock is abundant. Small pieces, with a good root or two to them are sufficient, and will extend a great deal in a single season. All digging and manuring should be done in November, after the decaying stems and leaves have been removed. If the work be delayed till midwinter there is danger of injuring any bulbs which may be coming up. A steel fork should be used on all occasions, but after digging and dressing are finished, nothing but a Dutch hoe should touch the ground. Herbaceous plants generally thrive best in a rather light, rich soil; consequently the best manures are leaf-mould and sand for heavy soils, and decayed hot-bed or well-rotted stable-yard manure and refuse composts from the potting bench when the soil is rather poor.—W.

Early-flowering Chrysanthemums.—These, though inferior in size of bloom and variety to the later-flowering kinds, are, nevertheless, well worth attention where a succession of bloom is desired. Large beds of them have been in great beauty for many weeks past in London gardens, and will in all probability continue in that condition for a long time to come. The plants do not grow more than 2 ft. high, are of a free, branching habit, and produce blooms in great abundance. The principal varieties are Madame Picœul, Precocite, indicum nanum, and Frederick Pill.—S.

Lobelia fulgens as a Bedding Plant.—We find the red-leaved variety of Lobelia fulgens to be the best autumn bedding plant which we have. Its reddish-brown leaves look well in summer, and it is now a mass of brilliant scarlet and brown, a condition in which it will probably remain to the end of October, or even later should the weather be favourable.—C. M. O.

Fuchsias amongst Ivy.—As the cultivation of the Fuchsia involves little or no trouble, there is really no reason why sorts that are of robust habit, free blooming, and fairly hardy might not be found not only in ordinary shrubberies, but also under the shelter of trees. Fuchsias make in the open pleasure-grounds grand summer beds and permanent ones; but when the plants are cut down for the winter, and the stools sheltered, as is customary, with a heap of ashes, the effect is the reverse of pleasing, whilst the birds persistently refuse to allow the ashes to remain undisturbed. The obvious cure for this would be found in associating Ivy with the Fuchsia, *i.e.*, covering the surface of the bed with plants of Ivy, which would soon become permanently established, and which in winter would afford to the Fuchsia stools all the protection from frost that would probably be required. The danger perhaps would be that fast-growing Ivy might choke up the Fuchsia plants, but the stools might be cleared and freed from the too close embrace of the Ivy every spring, and even some well-rotted manure might be dug in about the roots at the same time. The result of this arrangement would be that the plants would produce branches richly laden with flowers from a setting or ground-work of green Ivy, whilst in winter the beds would still be a mass of green leafage. There are not wanting an abundance of Fuchsias suitable for outdoor planting that would give variety of growth and of colour, the most robust kinds, of course, having the central position. Double sorts should be avoided. Any plantsman would easily furnish a selection that would be most fitted from habit and strength for the purpose. Plants that had been once before cut back hard, and which had thrown up a bushy growth, would be better than single stem plants, as the latter do not break so freely in the open ground the first year. The cutting back should always be such as to encourage fresh growth from near the roots.—D. N.

Increasing Herbaceous Plants.—Fibrous-rooted spring and early summer-blooming herbaceous plants, that have become too large, may now be divided; by carrying out such work at this season when the tops are dead or nearly so, the plants will bloom much better than if it were done in spring. All should therefore be removed or divided that require it, except such plants as the common White Lily, which will now be making active growth, and if the roots be disturbed it will have the effect of wholly or partially preventing its flowering next year. The majority of herbaceous plants are an exhaustive crop; consequently the ground in which they have grown, and which they are again to occupy, should be well enriched by a liberal application of manure and be deeply dug; this latter is essential where, as is often the case, the roots of shrubs or trees have access to it. Where any considerable number of the plants are thus to be got up, advantage should be taken of the opportunity to re-arrange such as may require it, not only by keeping the strongest-growing ones to the back, graduating regularly so as to have the lowest growers in front, but also mixing the colours in a way that will produce the best effect.

MICHAELMAS DAISIES.

These are now in full flower in London gardens, where at this season they are valuable on account of the comparative scarcity of bright flowering plants. These Asters, or Michaelmas Daisies as they are called, are plants that any one can grow if they have space at command and any ordinarily well-drained soil. They are not quite so showy as Chrysanthemums at a distance, but when closely examined they are more beautiful, their slender-rayed flowers possessing all the soft and delicate tints between white, rose, and purple, while the bright yellow centre bestows upon them an additional charm. All the kinds are perfectly hardy in this country, luxuriating in any soil or climate, and when once planted requiring little attention. They seem just as fresh and vigorous in the little forecourts and back gardens of Bermondsey and Stratford as in gardens more favourably circumstanced. All that has to be done to increase them is to cut a strong tuft to pieces with a spade and plant the divisions wherever they are to flower. Some of the kinds produce long spray-like panicles, which are extremely graceful in a cut state arranged along with sprigs of other late flowers, such as Fuchsia Riccartoni, double or single Marigolds, Anderson's Veronica, the silvery striped foliage of the variegated Arundo, and double or single-flowered Dahlias, bright-tinted Chrysanthemums, and a few pieces of the large white late-flowering Feverfew (Pyrethrum serotinum), which should be grown with the Asters, as its pretty, yellow-eyed flowers show to great advantage beside the bluish-purple and rosy-crimson large-flowered Asters, such as A. Novæ-Angliæ, purpureus, and roseus, which, together with A. bessarabicus, may be taken as three of the very best of the late-blooming kinds. One of the best of all the species flowering in October is the white and lilac-flowered A. versicolor, a charming little plant, just over 1 ft. in height, and yet as showy in its way as the large-growing kinds, some of which attain a height of from 6 ft. to 8 ft. in deep rich soils. When grown in pots in the same way as Chrysanthemums these Asters make excellent plants for greenhouses or rooms. The following are a few of the best kinds in addition to those already mentioned: Amellus, beautiful lilac-blue, with orange centres, flowers 2 in. in diameter, borne in dense masses during September and October, height 2½ ft.; Chapmanni, bright lavender, flowers medium size, very abundant bloomer, 5 ft.; grandiflorus, flowers purple, 2 in. in diameter, borne in great profusion during the months of October and November, height 3 ft.; hyssopifolius, lavender-blue, flowers medium size, very abundant bloomer, habit neat and compact, 1 ft.; lævis, bright bluish-lilac with yellow centres, flowers medium size, 3 ft.; laxus, bright lavender-blue with orange centres, flowers medium size, very abundant bloomer, 4 ft.; Novi Belgi, rich bluish-purple, golden-yellow centres, flowers large, abundant bloomer, 4 ft.; pulcherrimus, white changing to pale lavender, flowers large, 4 ft.; purpuratus, light purple, flowers medium size, 4 ft.

Group of Michaelmas Daisies (Asters).

Flowering Plants in Shade.—I strongly recommend anyone to give up struggling with flowers that will not grow well in shade and try Ferns, which will thrive, and, by a judicious mixture of Primroses, Polyanthuses, and bulbs, need not be too tame; in fact, I can imagine nothing prettier than a small window conservatory filled with cork and luxuriant Ferns and Lycopodiums, interspersed with Hyacinths or other flowers which can be nursed to blooming point in a window.—B. C.

ANEMONES.

Taking Anemones as they are understood in the seed shops, viz., the varieties of coronaria, of fulgens, and of hortensis or stellata, they are most successfully cultivated from roots. Of the forms of coronaria, double and single, they range from pure white through all the shades of lilac and purple to the richest glowing magenta; of fulgens, from the colour of a soldier's coat to bright crimson, including the double Peacock Anemone of the south of France, and stellata with its beautiful starry flowers. These all prefer a loamy, well-drained soil with partial shade, and if planted in succession will yield flowers for at least six months of the year. We have had a bed of coronaria varieties in bloom throughout June, and but for the hot sunshine and the absence of shade they would have continued a good way throughout July on soil moderately drained and somewhat inclined in summer to be harsh. These roots were planted in April. Plants of fulgens were in bloom from Christmas, along with the various single forms of coronaria. The Anemone of the florists and of the Dutch growers ranks amongst the oldest of garden flowers, and certainly amongst the most beautiful. Perfectly hardy, simple of culture, and eminently suited for the open border, it commends itself specially to all lovers of hardy spring flowers, and though resembling in appearance, is not to be confounded with the brilliant scarlet A. fulgens, which is an original species, and not, as our garden Anemones are, the product of intercrossing for many years. Anemone coronaria from the Levant, and A. hortensis of Italy, claim the parentage of the myriads of garden kinds of the present day. These are marked throughout by the same habit of growth and type of foliage, but great variation in colour, character, and markings of the flowers, some of which are single, others semi-double, and others as double as an incurved Aster. Roots of all these forms may be had from the bulb dealers at moderate prices—in fact, 100 roots of fine mixed sorts for 3s. is absurdly cheap; and if this quantity be purchased and planted in a small bed, it will be found that both in foliage and flower the result is all that can be desired. The figure on p. 371 represents exactly what these double French Anemone flowers are, and when it is added that they are produced in great abundance, are in height about 8 in., and are set in a mass of charming foliage, it will not be difficult to realise how very beautiful a bed of them must be. The most suitable time for planting the dried roots is towards the end of October, the soil being well prepared and manured. A little earlier or later will vary the time of blooming slightly, but the average blooming period is from the beginning of April, according to the season. The roots, if planted in beds for massing, should be 6 in. apart each way, but in borders four to six roots make a good clump. Cover to a depth of 2 in., and, where possible, add a surfacing of fine Cocoa-nut fibre refuse, as this affords much useful protection. The roots usually start into leafage almost immediately, and where a winter leafage is desired, the earlier the roots are planted the better. As soon as the foliage has decayed, if so desired, the roots may be lifted and stowed away until the succeeding autumn; the best plan, however, if the beds are needed for summer bedding plants, is to lift as soon as the bloom is past and lay the clumps in neatly under a wall or in some shady place, and allow them to remain until the autumn. The advantage of spring planting is that a succession of bloom is obtained until June. When the foliage is dead, and the tubers thoroughly ripe, they should be taken up, carefully dried, but not in the sun, and stored in a cool, airy place till the time of replanting arrives. During severe weather in winter it will be necessary to protect the borders in which they are planted with bracken, straw, branches, or similar material. Propagation is effected either by dividing the tubers at the time of planting, or by raising plants from seeds, which in some seasons are produced plentifully. For growing in pots for greenhouse or window decoration Messrs. Sutton and Sons remark: The first batch of roots for early forcing should be potted in September, and kept in frames, with but little water, until towards the end of the year, when they should be taken to a cool greenhouse, and be very gently forced into flower. By potting or planting in frames every three or four weeks during the remaining months of the year, the supply of flowers will be continuous.

ANSWERS TO QUERIES.

2898.—**Storing Potatoes.**—For many years I acted upon the following plan of storing Potatoes, and the result was invariably satisfactory, even in the worst seasons: After lifting them I had them carried to an outhouse, and as they dried all superfluous earth was removed. They were then taken to a frost-proof cellar and placed in a corner, secured by a narrow board to prevent undue scattering. The floor of the part selected was first covered thinly with well-slaked lime, and as the tubers were put in, additional lime was added to the successive layers. The dessicating properties of the lime preserve the skin of the Potato; also prevent damp and decay. Even if a diseased root should rot, the lime tends to keep the infecting fungus from spreading. I always had a good supply, fit for any table, up to and well into July. I depended for my winter stock upon the old Fluke, than which no better Potato need be wished for if carefully and skilfully grown; but it requires attention and experience to ensure a heavy and perfect crop. My soil was artificially made, rather gritty and poor, so I always manured and roughly dug it in the autumn. The essential points to store Potatoes well are these: Keep them dry, in the dark, as cool as possible, but absolutely secure from frost.—Berg.

2722.—**Rusty Water.**—It is a well-known fact that no water, *e.g.*, distilled rain, aërated, oxygenated, or carbonated, will dissolve sulphate of lead (not even when such are largely contaminated with sulphuric acid until it is concentrated to 60° areometric, and then with heat). Vegetable acids (*e.g.*, acetic acid) will not dissolve sulphate of lead. Sulphuric acid is made in leaden chambers, and may be concentrated by distillation from leaden stills up to a certain strength—say 60°. So "J. D." may feel reassured. Ordinary commercial sulphuric acid, or strong vitriol, is generally not pure, containing hydrochloric, nitric and sulphuric acid, and often arsenic, &c. The pure or the Nordhausen acids are very potent and caustic, and may be dangerous in inexperienced hands. Therefore, for safety and efficiency, I recommend such persons to use a strong solution of Epsom salts hot, rubbing this with a little sand by means of a close, hard scrubbing-brush or a Cocoa-nut husk over the lead surfaces, so as to brighten them, when the sulphuric acid immediately combines with the lead and the mag-

nesia, is deposited as a white powder, and thus will assist in removing greasy matters which may be on the lead, exposing the surface of the lead to the action of the acid. The only labour is in scrubbing the lead bright, and the time occupied in the action is a few minutes, and anybody can do it. I have acted on these facts for forty years, and told lots of people and plumbers and other tradesmen in lead. But I have never known any avail themselves of the information, because they could not understand it! As a matter of economy, all leaden utensils used in building should be made to assume a sulphate surface, as they are rendered insoluble by such agents as they are likely to be subject to, and they thus last much longer.—J.B.

2901.—**Mezereon Daphne.**—This plant is raised from seed only. I have a fine plant, which was a self-sown one under the parent plant. It is now fourteen years old and blooms abundantly. I let the berries drop off, and they root and come up the next year if not disturbed. No particular soil or situation is required. Mine is only common garden soil and faces the south, in length are slipped through four sockets, the plates on which they are fixed being screwed on each side of the ladder where it is joined. The ladder, which is frequently used in the garden, is very portable and handy for many purposes; it is 12 ft. high, has seven Oak rundles in the lower end and five in the upper. It was made by a carpenter and cost 17s.—Esprit de Corps.

2840.—**Unproductive Potatoes.**—The Champion Potato has enormous root power. It carries its healthy foliage through the period in which the disease is most active. It is the latest producer we have; its produce is then most abundant, and all the late-developed tubers sound. You could not have better advice than that already given you—to let it run its course fully; but I entirely differ with the adviser, from three years' experience, as to its value. Abundant produce, sound, and of good quality has encouraged me to plant thirty-five poles of it this year. In order to answer your query as to productiveness, I have just dug two average roots, and have 5 lb. of sound, good-sized tubers in a basket before me. They were affected with club. From that day to this I have always taken care to tread the seed-beds thoroughly after digging, a short toothed rake following, after which the seed is sown in shallow drills or broadcast, and the ground again trodden and raked. I have not had a clubbed plant since. Hard treading is a very important part of seed-bed preparation. Wireworm abhors a consolidated surface. A gas-lime compost helps much in getting rid of the swarm of insects which honeycomb a loamy soil.—J. M. Taylor.

3111.—**Climbing Roses.**—Take out the clay to the depth of 2 ft., and make the hole large enough to hold a wheelbarrowfull of compost, viz., two-thirds strong turfy loam from an old pasture and one-third of well-decomposed animal manure. If properly done, this will last for years with an annual top-dressing of manure. For a white Rose take climbing Devoniensis, or, better still, perhaps, for general purposes, Gloire de Dijon. For two red climbing Roses take climbing Duke of Edinburgh and climbing Charles Lefebvre. These, if properly treated, will, from

Group of Double and Single French Anemones.

but the old plant faced the north and did equally well.—Amateur.

3100.—**Blooms Dropping off Scarlet Runners.**—I see in Gardening Illustrated the question so often asked, Why do the flowers of Scarlet Runners drop off? From my experience as an amateur, I think the reason very simple, viz., because they never get water enough at the root. It is generally too much labour to carry the water in sufficient quantity, but by following the plan I adopt, watering becomes easy. I cut a trench in the ground from the water-tap across the garden to the Beans, and let the water run until I have given the Beans a thorough soaking, and this I repeat as often as I think it necessary, and the result is, that I have an abundance of crisp delicious Beans growing to 6 in. in length. I have had the same success every year since I adopted the above plan.—R. T.

3116.—**Pruning Ladder.**—Wishing to reach the roof of my house from a room inside where there is a skylight, I had a light folding ladder constructed; it is in two parts held together by hinges, and for safety when in use undoubled. Two strong square iron bolts 1 ft. planted in drills, 2 ft. 6 in. apart and 12 in. apart in the drills, which is not wide enough. There is fully 16 tons to the acre of good, picked table sample, according to every trial I have yet made. If you have crowded yours together, or grown them under trees, the crop will be small. Many will be disappointed with them by over-haste to lift them. I dug last year many of the finest plants on August 24 for an exhibition, but without success. A month later the crop was the best in the parish.—J. M. Taylor.

2968.—**Plums Cracking.**—Plums often crack through being imperfectly fertilised, or through some defect in the supply of food during the formation of the stone, or it may be constitutional. Perhaps the roots are getting too deep, or the soil may be deficient in lime. A good dressing of the latter substance forked in round the tree will do no harm and may do a deal of good, if, as I suspect, there is a deficiency of it in the soil.—E. H.

3114.—**Club in Cabbages.**—Suffering one year from this cause, I observed that some seeds of the Cabbage, which had fallen on the hard garden path close to the seed-bed, were not personal experience, do well, and give satisfaction.—William Walters, *Burton-on-Trent*.

3038.—**Road Sand for Cuttings.**—Would "B. T." be kind enough to describe the nature of the road sand he used for his cuttings, and whether it was taken from a road that had been mended with granite or some very soft stone, such as one often sees broken up to mend bye-roads with, or if it was obtained from a road repaired with flint or gravel? The sand produced by granite or soft stone would, I have no doubt, lead to the fatal results named by "B. T.," as it would be of a heavy black appearance, retaining when moistened a good deal of water, whereas the sand produced by gravel or flint is of a sharp, porous description, which soon dries, and would, if mixed with good garden soil after being riddled through a fine sieve, no doubt answer the purpose. Such sand is also very good for use in either flower or kitchen gardens mixed with the soil where it is wet and heavy, as it makes it work much better and assists drainage.—Swallow.

2913.—**Wintering Cuttings and Ferns.**—As our fair friend, Alice Grimes, only requires to preserve her cuttings from frost, and

which, I presume, mainly consist of such things as Geraniums, Fuchsias, &c., I feel happy to be able to inform her how she can do so. Place a good layer of Cocoa fibre or coal ashes in the bottom of your frame and plunge the pots to the rim in this. A bank of dry Moss, fibre, or any similar stuff, about 2 ft. thick, placed round outside the frame is requisite to exclude severe frost in the winter. The plants should be well rooted in their pots by this time, and should be plunged in the frame at once. A good covering of straw, hay, or some similar dry litter must be put over all during sharp weather. With these precautions, and a careful attention to air giving on all favourable occasions, such plants as Geraniums, Fuchsias, Calceolarias, &c., may be successfully wintered. If the Ferns are of hardy sorts they will live outdoors during the winter. The pots should be plunged to the rims in the border, and covered with 2 in. or 3 in. of dry Moss.—P. J. Kane.

2977.—**Cucumbers being Eaten.**—Either there are mice or woodlice in the Cucumber frame, which can only be ascertained on the spot. In the former case, set traps or use poison; in the latter, hunt up a few toads and place them in the frame. The evening is the best time to capture them; they will soon make short work of the woodlice.—E. H.

3042.—**Geraniums and Fuchsias not Flowering.**—There is more than one reason why Geraniums do not flower, as well as for the buds falling from Fuchsias. I expect in this case the plants are kept too close. Without air and sunshine no plants can flower. Manure water is of no use to plants that will not blossom. If gas is burned in the house that might account for the flower-buds dropping; but I expect it arises from weakness due rather to growing in a close, confined atmosphere than lack of nutriment in the soil.—E. H.

3036.—**Small Standard Apple Trees.**—"J. J." can graft on the Paradise stock and train them up to form small standards. The strong-growing sorts may be double grafted, being worked the second time standard high. What is called the English Paradise will be most suitable. Pears on the Quince will do treated in like manner—that is, train up the graft, pinching back all side shoots. When finally planted the stock in both cases must be buried.—E. H.

3049.—**Insects in House Slops.**—House slops should be used daily, or else be mixed with some deodorising substance, such as earth or ashes. They should not be permitted to stand long in a tub to impregnate the atmosphere and become infested with obnoxious insects. Any kind of liquid exposed to the sun would in time become changed in its character and be stocked with animal life. A lump of lime dropped in the tub will kill the insects and deodorise its contents any time.—E. H.

3021.—**Earthing Potatoes.**—The editor's reply to this question, right in itself, can I think be slightly added to—that the earthing-up causes the soil to lie lightly upon the tubers, and thereby is less resistance to their swelling or enlarging. I may add a few words upon what appears to me to be the best method of growing early Potatoes where horse labour is not used, and which is chiefly in practice on the southern slope of the Mendip Hills. The plan is to grow them in beds about 4 feet wide, any length, with just enough room between the beds for a man to walk to work the beds without treading upon them; the Potatoes are planted across the beds in drills as early in the spring as the weather will permit; when up 2 in. or 3 in. they are "spittled," as it is there called, or dug between with a light, narrow spade, only to be obtained in that neighbourhood, I think, after which, and when in a fit state, they are earthed up also with the spade, which is by far the best implement for earthing. The beds are never trodden upon. The spade I do not think to be the best instrument for "spittling" or digging between, but a narrow steel fork, 4¾ in. wide across the prongs—3 prongs only—13 in. long in the prongs, and entire length of prongs and handle 4 ft. 9 in. to 5 ft.; such a one I have in use, but it was specially made for me.—M.

2986.—**Potatoes in Pots.**—The best sorts of Potatoes to grow in pots are those that make short tops, such as the Early Kidneys and Rounds. I have had the most success with the old Ashleaf for very early work; then come Veitch's and Myatt's. The best soil is decayed turf mixed with wood ashes and charred rubbish. Christmas is soon enough to plant, and the pots should be near the glass. All the eyes except the strongest at the crown of the tuber should be rubbed off. I am doubtful if growing Potatoes in pots will be remunerative in a commercial sense, as the pots will cost a lot of money. Planting in light span-roof pits will, I think, pay better.—E. H.

3029.—**Mildewed Roses.**—Sulphur is perhaps the most general remedy for this plague to the Rose grower. Remove the leaves worst affected, and apply the sulphur when the leaves are wet from rain or a syringe. Give the trees a good washing next day. Canon Hole, in his book on Roses, page 297, refers to the application of soot, recommended by Mr. Rivers: "The trees were smothered with soot in the dew of the morning. This rested on them for four or five days, and was then washed off. The effect was marvellous; the mildew disappeared, the leaves turned to a dark green, &c." If sulphur does not cure, try soot.—William Walters, *Burton-on-Trent*.

3079.—**Moving Rose Trees.**—In my opinion and experience I should say do not attempt to remove Rose trees whilst the sap is flowing freely, but rather wait until say the middle of October or later, according to the weather, until the sap is somewhat at rest. At present my Rose trees are in active growth, and to shift any would be almost sudden death; the bark would be sure to wither, and the plant suffer to a certainty. Better to wait for colder weather than to run the risk of moving in September.—William Walters, *Burton-on-Trent*.

3111.—**Climbing Roses.**—There is no better light-flowered Rose than Gloire de Dijon for planting against a wall. Good varieties for associating with it are climbing Victor Verdier and climbing Jules Margottin. As the clay is so near the surface, it should be taken out some 10 in. to 12 in. in depth, which will thus allow for the formation of a good border 18 in. in depth. Roses like a good holding soil, so that about one-third of the clay may be retained, laying it out where it may get thoroughly pulverised, either by sun and wind or frost. When it crumbles to pieces in the hand it is in the proper state for use. The remaining portion of the compost may consist of any good garden mould, adding thereto some rotten dung. The best time to plant is about the latter end of October, but it may be deferred until the beginning of March. Procure plants in pots if possible, loosen the ball of earth, and spread the roots carefully in the prepared compost, pressing the soil firmly around them. About the latter end of March prune each shoot back to two eyes, mulch the soil with dung or Cocoa-fibre, and water in dry weather.—J. C. B.

3103.—**Management of Fern Case.**—If your Fern case is in the open air and cannot be placed under cover, your best plan will be to procure some bast mats, nailing them to the boards, and stuffing between with dry litter. The front and top may be covered up at night with mats. In this manner ordinary frosts will be excluded, and when the weather is very severe we think that a small lamp placed inside at night would ensure the safety of the inmates, leaving a small aperture in the highest part of the case for the fumes to escape. Your plan of furnishing the back and sides is very good, but we would prefer good fibrous peat for the plants to root into.—J. C. B.

3042.—**Fuchsias not Flowering.**—Perhaps "U. W." gives too much water to the Fuchsias. They should never be dry or stand in water. Both in the greenhouse and the garden ours have been very lovely. I often stand gazing at them with admiration, their graceful branches being loaded with flowers. I have a young plant, Miss Lucy Finnis, so full of flowers, I have taken some off lest the plant should suffer from having so many on. I think the single-flowering plants give me more pleasure; nothing can be more graceful than a dark one I have had in flower since February, and another lovely one, with a white corolla, which has a freak of sometimes having double flowers and sometimes single. Fuchsias, I find, require liberal treatment, but they repay liberally the care bestowed upon them. I syringe them often when the sun is not hot upon them; and when they show signs of poverty, I treat them thus: Round the inside rim of the pot, which should not be a small one, I set oyster shells—thin, small ones are the best; they give more room for stable manure which I put in; in fact, it is a simple way of mulching. In a few days there is a great improvement; flowers will appear in profusion. The most fastidious will forget to look at or think the oyster shells and the manure an objection, but that may be in a great measure removed by placing the pot in one made larger than the one the Fuchsia is growing in. One part of our greenhouse I always look upon with pleasure—a rockery, where Fuchsias, Ferns, Begonias, Primulas, Geraniums, and Roses flourish so well together. They look better nestling in among the stones, and far more natural than on stages—to me always an eyesore. I think a conservatory might be made more pleasing without stages. Of course those who indulge in bedding-out plants require them for a large number of flowerless Geraniums, &c.—Frosy Parc.

2974.—**Drying Flowers.**—At the commencement of this year I commenced to form a collection of flowers on exactly the same principle as "Janet" intends doing. The plan I adopt is this: On plucking the specimens I place them in a book, with a label attached, and when they are quite dry, a few days after, transfer them to another book (about the size of Gardening Illustrated) of clean leaves, whereon I gum them in as tasteful a manner as the number of specimens will allow.—William Hewes.

3039.—**Preserving Ash Berries.**—The Mountain Ash berries are preserved for winter decoration by putting them into strong brine. Mind and keep them well covered with the brine.—A. N.

2840.—**Unproductive Potatoes.**—I planted one sack of Scotch Champion in the spring. They are very free from disease. A gentleman went with me to see them, and I took a few roots up for him to see, and he said he never saw such a crop of sound Potatoes: from 10 to 16 at a root, all of which were very fine.—R. B.

3107.—**Plants for Small Garden.**—I should advise "North Shields" to try spring bulbs and plants, such as Tulips, Snowdrops, Crocuses, Hepaticas, and Lily of the Valley. The best Tulips for early blooming are Crimson King, Prince de Ligne, yellow; Duc Van Thol, scarlet and orange; and Le Blason, white and rose. I should also recommend Musk for the north side to bloom in summer, and for spring early Wallflowers. All these may be planted or sown now.—Butterfly.

3112.—**Sowing Iris Seed.**—English Iris seed, and, I imagine, the other varieties also, should be sown as soon as ripe, but they will not come up till next spring. Should the seed be not sown till the spring, it will remain in the ground till the following spring.—H.

3111.—**Climbing Roses.**—"Rhododendron" had best put Maréchal Niel (yellow) or Souvenir de Malmaison (pinky-white) for the middle, or perhaps the white Banksian would suit him best, and Princess Marie and crimson Boursault for either side. These require a good rich soil, and must be manured regularly twice a year.—Butterfly.

3044.—**Lost Roses.**—I have searched the catalogues of the principal Rose growers, but cannot find Rosa sulphurea or Mogador mentioned. No doubt application to Messrs. Cranston & Co., King's Acre, Hereford, would be successful; at all events, if the Roses referred to are in existence, that firm would be most likely to know of their whereabouts.—William Walters, *Burton-on-Trent*.

3098.—**Prickly Comfrey.**—I have found this to be an excellent thing for cows, pigs, &c., and though they may not eat it at first, yet after a day or two will eat it with great relish. It may be cut five or six times during the summer, but is of no good during the winter. A pamphlet on the above is published by Messrs. Christy & Co., 155, Fenchurch Street; price 1s.—H. T. C.

3174.—**Cutting Rhododendrons, &c.**—You may safely cut the plants in question down to any desired height, the best time for so doing being about the latter end of March, or if the Rhododendron is in bud it may be cut back after flowering.—J. C. B.

3180.—**Quick-growing Plant.**—The Euonymus is a quick-growing evergreen; but if you would prefer a graceful habited Conifer, you cannot do better than choose Lawson's Cypress.—J. C. B.

3123.—**Diseased Hollyhocks.**—Yours is by no means an isolated case. The Hollyhock fungus has now become one of those established evils which tax the patience and skill of the grower to obtain a mastery over. We do not know of any thoroughly proved effectual remedy, but believe that a timely application of black sulphur would check and eventually destroy it. Another season dust the leaves as soon as the first spots appear.—C.

3105.—**Propagating the Gum Cistus.**—These are easily raised from seed, which should be sown in pans of free soil in March, and kept in a frame until germination takes place, shading of course from sun, and keeping the soil in a uniformly moist condition. Cuttings may also be taken of the current season's growth, inserting them firmly in mellow soil in a shady situation about the middle of August.—C. B.

3179.—**Removing Rose Trees, &c.**—The middle of October is the best time for transplanting the plants mentioned. They do not then suffer any check, and lay hold of the soil before winter arrives.—B.

The Berry Bug mentioned by a recent correspondent is doubtless the harvest bug, well known by sportsmen and labourers as a most annoying pest: it buries itself in the skin and causes intolerable irritation. Strong carbolic soap or a carbolic lotion is a preventive to a certain extent, and a concentrated form of ammonia is a cure to some people.—B. C.

3217.—**Pruning Fruit Trees and Roses.**—What is the best time to prune Apples, Plums, and Roses?—E. S. [Apples and Plums from December till the end of January, Roses in March.]

3218. — **Mulching.**—*F. O'D.*—This means covering the surface of the soil with manure or other material to prevent evaporation, and so keep the soil cool and moist during summer.

3219.—**Saving Vegetable Marrow Seeds.**—*A Learner.*—When the Marrows are ripe and dry, cut them open and put the seeds into a vessel of water to free them from pulp. Then strain the water off, and spread the whole on a piece of canvas in the sun to dry; pick out the seeds separately, and put them into a paper bag till wanted for use.

3220.—**Edgings for Walks.**—What are the best and cheapest materials to use in making permanent edgings for walks of a flower and kitchen garden combined? —H. W. [Hard burnt edging tiles made at most large potteries.]

3221.—**Hydrangea not Blooming.**—A very good plant of Hydrangea hortensis in a perfectly healthy condition has not bloomed this year, nor shown any symptoms of doing so. It, however, bloomed abundantly last year and the year before. What is the reason and remedy? The same thing has occured in a neighbouring garden.—J. W. F. [The wood did not ripen well last year, owing to want of sunshine. Thin out all weak growths, and let the plant be exposed to the sun as much as possible, and it will doubtless flower well next year.]

3222.—**Wintering Window Plants.**—I have in pots in outside window boxes Ivy-leaved Geranium, Fuchsia procumbens, Harrison's Musk, Mesembryanthemum. Can these remain where they are through the winter? if not, will a cold frame do for them? or must they be taken into the house?—SUBSCRIBER. [Take them indoors. The Musk and Fuchsias might live in the frame, but not the Geraniums.]

3223.—**Selaginellas.**—What is the best time of the year for cutting down S. cæsia, autumn or spring? Does this Selaginella require to be kept in the stove all winter? or will a warm greenhouse be sufficient heat to start it into growth?—BLECHNUM. [Spring is the best time to cut down the plant. A temperature of 50° will do for it all winter. In early spring a temperature of 65° or 70° will be necessary to start it into vigorous growth.]

3224.—**Artificial Manures for Ferns.**—Will these manures be of any benefit to Ferns? If they are, what kind is used, and in what way? Amies' Manure is recommended by some for Adiantums, and a friend of mine says that Clay's Fertiliser will benefit all Ferns.—BLECHNUM. [They are beneficial when mixed with the soil when the plants are potted, or as a top-dressing when in active growth. Care must, however, be exercised in their use, as they are sometimes rather powerful.]

3225.—**Begonias in Windows.**—How shall I treat some tuberous-rooted Begonias which I have raised from seed sown in a pot in the spring? They are now about 2 in. high, and kept on a board in the kitchen window, where there is nearly always a fire. They have been transplanted to four plants in an ordinary sized flower-pot. [When the leaves and stems die down, just keep the soil from getting dust dry till they show signs of fresh growth in spring; then pot them singly into 3-in. pots, and shift them into larger ones as needed.]

3226.—**Moving Roses.**—Can I move two standard Roses at once, as I want the ground?—R. S. [Yes.]

3227.—**Wallflowers and Foxgloves.**—I have a lot of Wallflowers and Foxgloves in the seed-bed which were sown rather late, and consequently are yet only small plants. Would you advise that they be wintered as they are or pricked out? and in either case would they require any protection during severe weather?—C. G. [Prick them out now, and plant out finally in early spring. A slight protection during severe frost would be an advantage.]

3228.—**Manuring Fruit Trees.**—Will Apple trees that have been planted thirty years and upwards in an orchard derive any benefit from top-dressing with rotten manure? Their roots are in a cold, stiff clay.—HIGHGATE. [Certainly they will if the manure is just pricked into the surface soil.]

3229.—**Wintering Verbenas.**—I have lately struck some Verbenas and kept them in a frame close to the glass. They are beginning to run. Is it best to pinch the tops out? Could I keep them through the winter provided the frost is kept out?—J. G. FOSTER. [Give them plenty of air at every opportunity, and dust with sulphur should mildew make its appearance. Cut back in spring, and you will get plenty of cuttings.]

3230.—**Cinerarias.**—Having a frame and a greenhouse from which the frost could be kept out, could I get Cinerarias into blossom?—J. G. FOSTER. [Yes, if you have some strong plants now. It is too late to sow seed. Cinerarias dislike a dry heat, and frost is fatal to them.]

3231.—**Fruit Trees for Back Walls.**—What sort of fruit can I grow in a lean-to house against the back wall, which is always warmed by the kitchen fire? The house is 10 ft. high and 10 ft. wide, and has a south aspect. It is heated by hot-water pipes.—PLANTER. [Grapes, Peaches, Nectarines, or Figs would do well. Plant now in good turfy loam.]

3232.—**Rose Belle Lyonnaise.**—This planted on a lawn has made such vigorous growth, that I wish to put it against the house. Might it be moved now?—H. B. C. [Yes. If it is very large, care must be taken to keep the roots intact.]

3233.—**Pruning Pyramid Apples and Pears.**—*W. T.*—Let them alone till say December or January. Then cut all laterals in to two eyes, and shorten the leaders back to ripe sound wood.

3234.—**Asparagus Beds.**—When is the proper time for clearing Asparagus beds? and what treatment should I give them when cleared? I have eight beds seven or eight years old.—E. D. [When the tops have turned yellow cut them down. Remove all weeds from the beds, and put a good coat of half-rotten stable manure on them; also a little light soil from the alleys. They will need no further attention till spring.]

3235.—**Potting Carnations.**—I took some layers of a Souvenir de la Malmaison Carnation about three weeks ago. When can I take them up and pot them?—H. V. C. [Now, if they are rooted.]

3236.—**Wintering Ivy-leaved Geraniums.**—I have some fine Ivy-leaved Geraniums which I have grown in boxes all the summer. I should be glad to know how I can winter them. Should they be cut back? and, if so, when?—JIMMIE. [Cut them back slightly and pot them, or keep them in the boxes till spring. You can winter them in any place from which frost and damp are excluded provided light and air can reach them.]

3237.—**Chrysanthemum Burridgeanum.**—*Ambergate.*—Sow in deep rich soil either now or in March.

3238.—**Beetroot in Pots.**—*J. D. McN.*—You will want deep pots to grow Beet to perfection. Sow in good loamy soil in April, putting two or three seeds in the centre of each pot, pulling out the weakest plants when fairly up, and leaving the strongest one only.

3239.—**Uses of Hops.**—*L. H.*—These are useful to plunge pots in during winter, but are of very little use as mould even when well rotted.

3240.—**Lemon Tree in Winter.**—I have successfully grown from the pips of a Lemon a small tree about 2 in. high. What shall I do with it in winter?—WILL O' THE WISP. [Keep it in a warm window.]

3241.—**Seedling Cockscombs.**—I have some seedling Cockscombs 3 in. or 4 in. high, which I sowed, not knowing them to be annuals; will they keep in a cold frame?—TYRO. [No; they want a warm temperature. They would have succeeded fairly well if they had been planted in the open ground in June.]

3242.—**Fowls' Manure.**—I have some fresh fowls' manure and some well-rotted stable manure. Would it be well to mix these in applying them to the ground? or in what way can I apply the fowls' manure.—TYRO. [Mix them together, adding a little soot.]

3243.—**Wintering Dahlias.**—How can I keep Dahlias during the winter? I have had some plants for several years, but I have always nearly lost them in winter. This summer I have taken a number of cuttings in small pots, and I have them growing well in a cold frame. Any information as regards keeping the cuttings, also the tubers, would be gladly received.—J. P. W. [As soon as the frost cuts the leaves, cut off the stems to within 1 ft. of the ground, lift the tubers, and store them in dry soil or sand in a shed or similar place from which frost is excluded. Plunge the pots of those you have in the frame several inches deep in ashes where they are.]

3244.—**Keeping Fuchsias in Cellars.**—*Tyro.*—If in pots, lay them on their sides in the sun until frost is likely to occur, then shake off the leaves and store the plants in the cellar. They may be watered a few hours before being stored away, and they will then require no more water till the spring, when they begin to grow.

3245.—**Antirrhinums in Winter.**—*Bob.*—These are perfectly hardy in dry, well-drained soils. If your plants are not strong a little protection would be advisable.

3246.—**Heating Frame.**—I have a glass frame 3 ft. by 3 ft., projecting from a window facing south. Will a paraffin lamp be sufficient to heat it during winter?—CAMBERWELL. [No doubt it would, but the fumes of paraffin are injurious to plants. It would be better to grow such plants that would need no more warmth than that which might be afforded by the room.]

3247.—**Keeping Coleus.**—*Anna.*—In order to keep these, a light, airy house and a temperature of at least 50° during winter is necessary. Cuttings strike readily in spring in a warm house or frame.

3248.—**Pruning Fruit Trees.**—Some of my Apples, Pears, and Plums have been left unpruned this summer. What had I best do with the long shoots?—S. E. [Thin out the unripe shoots and those which cross each other, and shorten the others back slightly. We presume you mean bush or standard trees.]

3249.—**Heat for Plants in Winter.**—Having a Vinery which I wish to turn into a greenhouse in which to keep Geraniums, Gloxinias, Coleus, Fuchsias, &c., would you inform me what heat I should keep it up to in the winter to suit them all? and also if one small stove would be sufficient to keep the heat up, as there are no flues through it?—G. C. M. [The temperature must not be below 50°, or you will lose your Coleus. The Gloxinias will require quite that heat, excepting whilst they are in a dormant state, when a slightly lower temperature would not hurt them much. The Fuchsias and Geraniums will do very well in the heat mentioned, and give a little flower during winter. One small stove will be of little use.]

3250.—**Wintering Castor-oil Plants.**—I have some very fine Castor-oil plants 6½ ft. high in blossom now, and with splendid foliage, planted out in July from seed sown in April. Can I save them through the winter? or propagate them in any way besides by seed?—H. M. O. T. [You could save them by lifting them and potting them, or by planting them in a warm greenhouse or Vinery, but the best way is to raise them yearly from seed, as by this means much healthier and better plants are secured.]

3251.—**Greenhouse too Hot.**—I have a small greenhouse, 12 ft. by 8 ft., heated with hot-water pipes heated by a tubular boiler in shed adjoining; sometimes even in hard weather I am unable to regulate the heat, and it gets to 60° at night, when the plants get terribly dried. May I venture to water the plants in such a case, or steam the pipes? They were put in a year ago, and are getting very rusty. Should they be painted? and with what?—ENQUIRER. [You must not steam the pipes. You may damp the floor and stages, but your true plan is to regulate the heat by means of a damper in the chimney and the ash door under the fireplace.]

Begonia and Geranium Leaves Falling off.—*M. P.*—We should say your plants are exhausted after the season's flowering. Try repotting into some good rich loamy soil.

W. D. M.—The Grape shoot is mildewed; dust with flowers of sulphur.

Pentstemons.—*J. S. M.*—Pentstemons do not require protection during the winter; they are hardy.

Gladiolus Dying off.—*Illawarra.*—You do not say what treatment they have been subjected to.

Abbreviation of Botanical Terms.—*W. B.*—The abbreviation fl.-pl. means double flowered.

Leaves Disfigured.—*H. H.*—Red spider.

Names of Plants.—*C. M. E. A.*—Clematis Jackmani.——*Rev. L. A. B.*—Large-flowered Aster (A. Amellus); small one, A. turbinellus.——*Subscriber.*—Large leaf, Lophospermum scandens; other, Mikania scandens.——*Thrift.*—Bidens (species).——*Mrs. T. S.*—Lonicera Ledebouriana.——*M. C. R.*—Giant Knotweed (Polygonum cuspidatum).——*Miss Std.*—Touch-me-not (Impatiens Noli-tangere).——*C. M.*—Fern (Pteris tremula cristata).——*Erica.*—1, cannot tell; 2, E. gracilis; Ixora coccinea; we cannot name the Pelargonium.——*G. S.*—Botanical name of Portugal Laurel, Cerasus lusitanica.

QUERIES.

3252.—**Spring and Autumn Flowering Shrub.**—Can any one tell me if there is any hardy flowering shrub which blooms both in the spring and autumn in a north-east aspect?—ILLAWARRA.

3253.—**Mildew on Forget-me-nots.**—What is the cause of a white sort of mildew attacking my Forget-me-nots? It first appears in white spots on the leaves, and then gradually extends over the whole plant, making it appear as if it was covered with a white mould. This occured in a pot which I had in a room window last spring, and now I find several plants are going the same way out in the open ground.—A.

3254.—**Indian Corn in Pots.**—Being anxious to grow some plants of these for the window, I shall be thankful for the plainest instructions that can be given respecting them. I have tried several times and quite failed, till this month I put nine seeds in a pot, and was much surprised to find five of them up in seven days. They are from ½ in. to 1 in. high. What must I do to bring them on? Will some one also name several other things I may try that are not generally grown, such as Acorns, &c.?—SUGRAM.

3255.—**Arum Lilies not Flowering.**—The last two years my Arum Lilies have not flowered. I have grown them for the last four years, and they have always flowered very well till the last two. After flowering I turn them out of their pots and put them into the ground for about a couple of months, then repot them in fresh leaf soil, and water them plentifully during the spring and flowering time. I also take the young plants from the old ones and plant them separately. Can any one tell me whether this is the right treatment for them? I shall be much obliged for any information on the subject.—B. J. C.

3256.—**Plants for a Shady Border.**—What kind of flowers or plants will grow best in a bed so shaded by a high north wall that it is entirely without sun until the end of June? The soil is rich, and I want something that is hardy and that will bloom during the spring and early summer months.—F. O'D.

3257.—**Pruning Hardy Passion-flower.**—Will any reader tell me if I must cut back my hardy Passion-flower? if so, when and how? It was planted in March, and has grown 8 ft.—E. S.

3258.—**Slimy Growth on Lawns.**—I should feel much obliged to be told the cause and cure of a slimy, seaweed-like growth all over my lawn. This is the second or third year of its appearance.—MRS. C.

3259.—**Wintering Roses in the West Riding of Yorkshire.**—Can any one give me any information on this point?—J. H. B.

3260.—**Plants for Windows in Winter.**—What plants can I keep through the winter in a window where the temperature is from 40° to 50°? I have no frame, but could shelter young plants in the corner of an area till they are large enough to remove to the house.—MOUSIE.

3261.—**Bulbs in Vases.**—I want to plant some Hyacinths and Crocuses in an old china bowl, which of course has no drainage. What soil ought I to put them in? and what treatment do they require?—MOUSIE.

3262.—**Substitute for Grass.**—I have a narrow Grass bank about 2 ft. high surmounted by a hedge; it looks very neat and effective when kept in perfect order. Can any one tell me, however, of some close-growing plant that would form a good substitute for the Grass without requiring the labour and attention which must be bestowed on the latter?—J. J.

3263.—**Transplanting Rhubarb.**—Will any reader be kind enough to inform me what is the best time to transplant Rhubarb?—C. F., *Forest Gate.*

3264.—**Unfruitful Fruit Trees.**—My Apple and Pear trees have all a tendency to run to wood and give very poor crops of fruit. I have tried root-pruning them, but it appears to do little or no good. Can any of your readers tell me how to treat them? Most of them have been planted about twelve years. The soil is very light and sandy, but has been well manured and worked, so that it is not poor on the surface, there being 14 in. of good soil above the sand.—A. S.

3265.—**Flowers for Spring.**—What are the best kind of flowers for outdoor spring bloom? and when should the seed be sown?—M.

3266.—**Saving and Sowing Flower Seeds.**—Will some one inform me how to gather seed from Asters, Verbenas, and Stocks? and when, too, is the time for sowing seed of the same for blooming as early as possible next year? When is the best time for sowing seed of Indian Pinks? and what soil is the best?—AMBERGATE.

3267.—**Brier Cuttings.**—I should be glad if your correspondent "C.," who gave excellent directions for Brier cuttings on which to bud Roses in GARDENING, September 11, would state what length they should be.—H.

3268.—**Outdoor Vines.**—I have found a Black Frontignan Vine, trained against a south wall, ripen its fruit admirably in such a season as 1878, for instance, but I never have been able to get any bunches really ripe from any other Vine, not even from the white Sweetwater in the warm season of 1870, though it is common to see this planted against dwelling-houses. Is there any other Vine besides the Black Frontignan that would be likely to ripen its fruit out-of-doors in a tolerably sheltered situation in Dorsetshire?—A. K.

3269.—**Cement for Pipe Joints.**—In my greenhouse I have built a brick stove in the usual way, and, in order to avoid expensive brickwork, have obtained some 6-in. drain pipes, unglazed and without sockets. I have used, to make the joints good, plastic clay, with plenty of sand mixed to prevent contraction. I find this will not answer, as the clay cracks, do what I will. I am

told Portland cement will not answer, as the heat would reduce it to powder. Is this so? What can I use or do to prevent the joints leaking, expense being considered? —Tyro.

3270.—**Roses for Pot Culture.**—Will some one name a few good Roses for pot culture in a cool greenhouse, having regard specially to good habit of plant and scent of flower, such as would allow of severe pruning for shaping, if found requisite? I have seen Roses in pots with very diminutive leaves and flowers. Do these constitute a distinct class, as no catalogue seems to notice them? If one only, what is the name?—Quidnunc.

3271.—**Chrysanthemum Halleri.**—Will this stand the winter in the open ground? if not, how can I preserve it, or cuttings, without glass?—H. B. C.

3272.—**Perennials for Succession.**—If I give up bedding plants, what perennials can I have to make a successive and brilliant show? I have over half an acre of flower garden, and so can have all kinds. I should like a list with height, colour, and time of planting. When and how ought Christmas Roses to be planted? and do any other plants blossom at the same time as they do? I want to have a bright and profuse show in winter and early spring.—At a Loss.

3273.—**Plants for a Cool Greenhouse.**—I have converted an old-fashioned summer-house into a cool greenhouse, heated by a paraffin stove to keep the frost out. The house has S.W. and E. windows, giving plenty of light. What hardy plants, especially creeping ones, can I keep in this house to flower from now to summer? I want to make the house as gay and as lively as I can without injuring my bedding stock.—At a Loss.

3274.—**Prickly Comfrey.**—I planted a rood of land six years ago with roots of this. They cost £5, but have not paid 5s. return. I should be glad if some one could tell me the best way to get rid of it; cows will not eat it. Lucerne by the side of it yielded an abundant crop.—R. Bensley, *Hilgay*.

3275.—**Grubs in a Greenhouse.**—How can I catch these.—T. P.

3276.—**Fruit Trees for Suffolk.**—Can any one name me a few good sorts of Apples, Pears, and Plums for standards, pyramids, espaliers, and walls for my garden in east Suffolk? Soil light; farmed for cereals and roots for many years; now sold for building. Position—elevated above the town.—E. C. T.

3277.—**Violets not Flowering.**—I have several plots of Violets, good healthy plants, in fine leaf, but they never flower. Could any one tell me what treatment they ought to receive to make them bloom?—H. H.

3278.—**Saving Aster Seed.**—I have a few fine Asters, and I would like to save some seed from them. Will some one say the best way to do so?—J. P. W.

3279.—**Basket Plants.**—Will some one give a list of plants for hanging baskets for a cool greenhouse? If convenient, let them be arranged under three heads: evergreen, deciduous, and annual (including biennials, if any). Not erect-growing plants or climbers, but genuine trailing or drooping plants. I think that thus a dozen baskets might easily be had, or more, containing plants all different, and each basket filled with suitable subjects. It would be obviously unsuitable to grow side by side two plants, one of which would make twice the growth of its neighbour. I think that an impetus may be given to a way of growing plants which is not yet at all valued as it ought to be. If an abbreviated list only can be given, let the best be named. A few might be noted suitable for centre, also for climbing the suspending wires, though of course these would not be trailers. Perhaps a selection of winter bloomers might be given separately.—Quidnunc.

3280.—**Double Pyrethrums.**—I should feel obliged if some one would explain in Gardening Illustrated the culture of double Pyrethrums, their winter treatment, and from cuttings. I have some very small plants just received from a nursery, and have potted them in ordinary soil.—A. C. D.

3281.—**Plants for Shady Wall and Roof of Conservatory.**—The end wall of my conservatory is continually shaded, owing to 4 ft. of the roof being necessarily without glass. What will be the best to cover such a wall, and also the part of the roof without glass? Will Lapagerias do?—C. J. R.

3282.—**Growing Cockscombs.**—Will any of the readers of Gardening tell me how to grow Cockscombs? the sort of soil they require, and the degree of heat? also the best time for sowing, &c.?—John D. McNally.

3283.—**Cucumber House.**—Will some reader give me instructions as to the best way to make a bed over a brick flue for growing Cucumbers? I intend building a wall 3 ft. 6 in. from the front wall, which will be 3 ft. 6 in. high. How should the brick flue be built—in the centre, or close to the front wall? and how should it be filled in?—A Subscriber.

Water Bouquets.—These can be made very easily, and form an exceedingly pretty variety of table decoration. The requisites are a glass shade (10 in. in diameter and 12 in. in height being the most suitable size), a substantial decanter stopper with flat head, a glass stand having a depth of about ½ in., and flowers and foliage. Arrange the latter as a bouquet loosely, tying the stalks to the stopper. Having a tub or bath containing sufficient depth of perfectly bright water, to immerse stand, shade, and flowers, insert the bouquet in the shade, place the shade upon the stand, and then, withdrawing the whole affair from the water, the shade will be found quite free from air bubbles, provided the surface of the glass stand is perfectly flat and close fitting to bottom. A few experiments will show which flowers and leaves give the best effect, also the best size for bouquet.—Scot.

POULTRY.

Much has been written about sawdust in the garden. I will with your permission give my experience of its use amongst poultry. I had some weeks since a brood of young chickens ill with that most troublesome complaint called by some gapes; I think it is more like bronchitis. One little chick was so ill, I expected its death daily. They had clean water to drink, their food being soaked bread and boiled rice, a little grease (without salt). The floor of their sleeping pen was made clean and sawdust thrown down, covering the floor about ½ in. In two or three days the little one, that breathed with difficulty standing with its mouth open, was well and the others improving. I do not give all the merit to the sawdust, but I think it is very purifying amongst chickens. We now use it in the hen-roost and dog-kennel. Our poultry are well fed; they have the run of a grass field plantation and yard (and often take possession of the garden); they ought to be healthy, but I lose more than I like every spring with the troublesome complaint before mentioned. I cured one once by giving it daily about half a teaspoonful of cod-liver oil. Before closing this paper may I ask if some of your readers will kindly tell me where I can purchase a couple of young pullets of the old-fashioned Polish breed mentioned by "Andalusian" in Gardening, November 15, 1880 (p. 571). I know by experience there is not a better sort. My last old hen died some time since, and I have not been fortunate enough to replace her.—Cymro.

Vermin in Fowl's House.—Allow me to suggest the following plan, which I have tried and found to answer admirably: Turn all your fowls out into the yard or run; then having closed up all the apertures in the house that smoke could not get out of, collect all the hay from the nests and put with it some damp brown paper to smoulder; set fire to it, go out, and close the door; leave it for about a quarter of an hour, so that the smoke gets well into all crevices; then open the door and let it out; meanwhile mix a little carbolic acid with some limewash, and with a brush well coat the interior of the house, taking care to let it run into all cracks, the ends of the perches, and behind, and all round the nests, for you will find the vermin by thousands in such places. Having finished the lime-washing, throw your house open to let it get nice and dry and fresh for the fowls at night; the smell of the carbolic acid will in no way hurt them, only do not get it on your clothes or fingers, as the result might not be pleasant.—W. C. N.

Vermin in Poultry.—These pests have been unusually plentiful and strong this summer. Nothing seems to reach them like carbolic acid. It can be bought very cheap at oil-shops and chemists, and should be used freely in the houses, either mixed with limewash in the proportion of a quart to a pailful of wash, or with water, half and half. In the former case it should be applied to the whole interior of the house, and all fittings such as nest boxes and perches should receive a coat, working it well into all crevices and corners with a proper whitewasher's brush. If mixed with water and kept in the house in an open vessel (but out of the reach of the birds), and a little sprinkled every day on the floor and walls, it will work wonders in keeping the number of vermin down. The runs also round about the house may have a sprinkling occasionally with advantage. Another plan is to fumigate the houses with sulphur, by burning a quantity on the floor, having previously stopped up all openings and guarded against any intrusion on the part of the fowls. Keating's Powder is very effectual, but is also expensive where several houses have to be seen to. But all methods for exterminating vermin are useless unless the houses be regularly cleaned out and a good dry dust bath be provided. During the moulting season the feathers should not be allowed to collect in the houses, as they afford a capital harbour for vermin.—Andalusian.

White Dorking Cockerel.—Can any of your readers of poultry news inform me where I can get a fine white Dorking cockerel hatched early this year?—Constant Reader.

Spanish Pullets.—In answer to an enquiry respecting first-class Spanish pullets in last week's number signed "Northampton," I think they can be had at Wyke Farm, Osterley Park, Isleworth.—T. J. B., *Crauford*.

Rearing Poultry.—Baily, of Mount Street, has published a very useful 2s. 6d. book. Tegetmeier's "Book on Poultry" also contains many useful hints on the above subject.—J. D.

Fowls Moulting.—What is the proper treatment for fowls whilst moulting?—T. P.

Houdan Fowls.—The following is a list of a few first-class dealers and breeders of Houdans: Messrs. Fowler, Prebendal Farm, Aylesbury; Messrs. Meredith, Tathwell, near Louth; Messrs. Baily, Mount Street, London, who also import Houdans direct from France. —J. D.

Fattening Chickens.—I have several good-sized chickens, which I keep shut up, and feed them with Maize and Barley, also middlings mixed with hot water, but they do not seem to get fat; am I treating them in the proper way?—E. D

BEES.

Supers for Bees.—Will "Apiarian" oblige by giving me some instructions as to how I should proceed to act under the following circumstances? —Last year I had a hive of bees given me in an old-fashioned straw hive. During the winter and early spring it became necessary to feed them; and I cut a hole 2 in. or 3 in. in diameter at the top of the hive, so as to easily supply them with food. This I did until they were able to maintain themselves. In June they swarmed, which swarm I had put in a double straw hive. Judging from the weight of both hives, I fancy they have gathered a fair quantity of honey; and, with a view to get some, I put a glass super on each hive, but have failed to induce them to work in them. Will "Apiarian" kindly tell me the cause? and the diameter of the glass supers I should use? and whether the glasses should have a ventilating hole at the top? and also a little melted beeswax be rubbed over the top as a guide? I have not used the upper half of the straw hive as a super, only covering the glass with it as a protection. Is this correct?—J. B. W.

HOME PETS.

Taming Canaries.—Can any reader inform me the best way to get canaries quite tame, and to come out of the cage?—J. F. W.

Canaries with Asthma.—"Bluebell" had better get some Tibb's Canaradyne, and give the bird two drops into its beak with a rounded, not a pointed, quill once a day. It is sold in 6d. and 1s. bottles. Any chemist will get it.—J. F. H. W.

Canary Losing its Feathers.—My canary used to be kept in a warm room, and was always pecking himself, losing a great many of his feathers, and made a queer noise in his throat, as mentioned in the Gardening lately. This spring he was put into a cool room which gets the morning sun for about an hour each day. I open the window when it is fine. The bird has his bath of cold water each alternate day. His food consists of Canary seed, Rape, and Millet mixed; no Hemp; he has been better without it. He has green food fresh every day, is now quite well, and as noisy as he once was quiet.—E. W. A.

REGISTERED FOR TRANSMISSION ABROAD.

HARDY FLOWERS: THEIR USES AND CULTURE.

As this is the time to prepare for the harvest of another year's beauty, I want to speak to those who hold that the flower garden, or terrace garden, or parterre, or whatever they like to call it, is not a proper place for hardy flowers. The ugliest and most needless terrace garden in England may be adorned in the most beautiful way with hardy plants alone. People are beginning to see the folly of the "bedding-out" system, and a little pressure is put in the direction of change. When gardens have been arranged for the expensive "show" now common, it is not always pleasant or convenient to turn to a different system; and we frequently hear the remark that hardy flowers are "all very well in their place," and so on. According to this crude notion one may have a Verbena in the flower garden, but must not bring superb scarlet or other Lilies near it! Are we not all wrong in adopting one degree, so to say, of plant life as the only fitting one to lay before the house? What should we say of the gardener who filled his conservatory with low soft-wooded plants only and omitted from his collection Camellia, and Palm, and Heath, and Azalea? This is what we have long been doing in the flower garden, and by changing this we can effect great good at once. We have so long been accustomed to leave flower beds raw, and to put a number of plants out every year, forming flat surfaces of colour, that no one ever thinks of the higher and better way of filling them. But surely it would be desirable to consider whether it would not be advisable in most cases to fill the beds permanently rather than leave them in this naked or flat condition throughout the whole of the year. In Nature, vegetation in its most beautiful aspects is rarely a thing of one effect, but a union or mixing of different types of life, and a succession of different seasons of b'ooming. So it is in the garden; the most beautiful effects must be obtained by a variety of different forms so combined that they help each other, and give us a succession of pictures and of varied interest, instead of monotony or bareness. If any place asks for permanent planting it is the spot of ground immediately near the dwelling house, for no one can wish to see large grave-like masses of soil frequently dug and disturbed near the windows, and few care for the result of all this, even when the ground is well covered during a good season. But everybody could form beds that would look fairly well at all seasons by the use of our choicer shrubs of many kinds—Spiræa, Rhododendron, Azalea, Dwarf Cypress, Retinospora, Japan Quince, Tree Heath, Comptonia, Coronilla (in mild districts), Viburnum, Clematis, Aralia, Honeysuckle, Weigela, Sweet Brier, Vine, Hydrangea. Arbutus (Croomi), Azara, Skimmia, Rock Rose, Tamarix, Daphne, Yucca, Tree Pæony, Escallonia, new large-flowered Hypericums, choice Hollies, Osmanthus. Why should we not use a beautiful Andromeda, or a Kalmia, or a rare evergreen Barberry in the flower garden in the same way as we do a Camellia, an Acacia, or a Tree Fern in the conservatory. We could do so with infinite happy effects, and one of the secondary results would be improved culture for and much more beauty from our many choice hardy shrubs now so often neglected in the shrubbery. Thoroughly prepare the beds, put in choice shrubs, which, never growing into low trees or tall shrubs to obscure the view, nevertheless adorn the earth all the winter as well as the summer, and give us a broken as well as a beautiful surface. Between them in open spaces and round their feet, so to say, allow for the planting of a variety of the choicer hardy plants, which would come up and flower and pass away, and vary the scene and give us pictures following the seasons. We should not have any definite pattern to weary the eye; but we should have quiet grace, and verdure, and little pictures month by month. The beds, filled with shrubs, and garlanded with Ivy and other evergreens and creepers, would afford everywhere nooks and spaces where, among the shrubs, some of the many fine, hardy Lilies could be grown, and the Tritomas, Gladioli, Phlox, Pentstemon, Iris, tall Anemone, Pæony, and Delphinium. The choice shrubs recommended for such beds are not gross feeders like trees, and seem to encourage the finer hardy bulbs and flowers. The shrubs also relieve the plants by their bloom or foliage, and when a Lily or Cardinal-flower fades after blooming it is not noticed as it might be in a stiff border. Among our flowering shrubs we have the perpetual-flowering Rose on its own roots to help us with our plans. This in many forms is perhaps the greatest treasure of all, and its effect so disposed will be better than in any special arrangement. We must get rid of the old collection of ugly sticks formally arranged as a Rose garden. It should, apart from its use in borders and mixed groups, be planted in a natural manner, without formality, in simple, large, well-prepared beds, the plants trained as bushes or pegged down, so as to let their foliage and shoots spring from the

TYPE OF BEST HARDY FLOWERS: THE ROSY HEART (DIELYTRA SPECTABILIS).

ground. No Rose beds can be made in this way without offering positions for beautiful hardy plants. We may have many flowers ben[illegible] the Roses, or to stand among them or a[illegible]ve them like fair Lilies. One of the prettiest garden borders I know of is against a small house. At the back or garden side, instead of the walk coming near the windows, a bed of various choice shrubs, varying from 9 ft. to 15 ft. in width, is against the house and out offices. Nothing in this border grows high enough to intercept the view, but just high enough to hide the walk. Looking out of the windows on the ground floor of the house, one sees the foliage and bloom of the border, but not the walk, the eye reaching a green lawn beyond. Among the shrubs are planted tall evening Primroses, and Lilies, and Meadow Sweets, and tall blue Larkspurs; and these, after the early shrubs have flowered, peer above their leaves.

Selections of Hardy Flowers.

So many of the errors and disappointments as to hardy flowers and flower gardens, too, have arisen from a bad or careless selection of plants, that we publish *The Garden* series of selections of hardy flowers. These have been made by persons thoroughly familiar with the plants in question, and are brought down to the latest date, omitting very new or rare species. They have been revised again and again with care, and may be recommended to our readers inexperienced in these plants, as a safeguard against purchasing inferior or weedy species, which are far too numerous. We begin this week with the hardy herbaceous division—vigorous plants for borders, beds, or groups, which are thoroughly hardy, and may be grown on any soil. All soil, however, for such plants should be deep, well enriched, and thoroughly prepared at first. The colour and height of the plants in the annexed list are given in order that planters may exercise some little taste in their arrangement.

Arrangement of Hardy Plants.

The many beginners in the culture of hardy flowers who are at present considering their operations will do well to bear in mind the following points:—

Select only good plants, and throw away weedy and worthless kinds; there is no scarcity of the very best, as will be seen by our list below.

Put, at first, the good kinds selected in lines across 4-ft. nursery beds, so that a stock of young and strong plants may be at hand, and that you may be able to exchange with others as well as form arrangements or groups in any way desired.

The mixed border is only one of many ways in which hardy flowers may be grown. But as a mixed border will be formed by many, it is essential that it should be well and carefully done. Place it where it cannot be robbed by the roots of trees; see that the ground is thoroughly prepared, and rich, and deep enough—never less than 2½ ft. of the best friable soil. The soil should be so deep that in a dry season the roots could seek their supplies far below the surface. On the making of the border depends, in fact, whether the vegetation will be noble and graceful or stunted. If limited to one border only, some variety

in the soil will be necessary to meet the wants of peat and moisture-loving plants.

In planting, plant in groups, and not in the old dotting way. Never repeat the same plant along the border at intervals, as used to be done with favourites. Plant a bold, natural group of it, or two or three groups if you must have so many, and then be done with it.

Do not be particular to graduate the plant from the back to the front, as is generally done, but occasionally let a bold and sturdy plant come towards the edge; and, on the other hand, let a little carpet of a dwarf plant pass in here and there to the back, so as to give a broken and beautiful instead of a monotonous surface.

Have no patience with bare ground. Cover the border entirely with dwarf plants; do not put them along the front of the border only, as used to be done. Let Hepaticas, and double and other Primroses, and Saxifrages, and Golden Moneywort, and Stonecrops, and Forget-me-nots, and dwarf Phloxes, and many similar plants cover the ground everywhere—the back as well as the front of the border—among the tall plants. Let these little ground plants form broad patches and colonies here and there by themselves occasionally, and then let them pass into and under the other plants. A White Lily will be none the worse, but all the better, for having a colony of creeping Forget-me-nots about it in the winter or spring. The charming variety that may be thus obtained is infinite.

The border should remain for years without any digging in the usual sense. All digging operations should be confined to changes and to the filling up of blanks with good plants, and to the rearrangement of ground plants. If the border is in the kitchen garden, or any other position in which it is desired to cut it off from its surroundings, erect a trellis at the back of it from 6 ft. to 10 ft. high, and cover this with climbing plants—Clematises, Roses, Sweet Briers, Honeysuckles, or any beautiful and thoroughly hardy climbing plants, not twined too stiffly, but allowed to grow into free wreaths. Roses of the very hardiest kind only should be employed, so as to guard against gaps in severe winters; the old single Clematis, the mountain and the sweet autumn Clematis (C. flammula), as well as other single kinds, should have a place here as much as the larger forms. The trellis may be made in the usual way, of wood or iron, or in a simpler and certainly handsomer way, of rough tree posts and branches.

In case the soil is not very deep or not very well prepared, and the surface not covered with green life in the way laid down, it will be well in many cases to mulch the ground by placing 2 in. of some light sweet dressing on it in summer. With all plants of doubtful merit which grow coarsely and are apt to overrun

Type of Best Hardy Flowers (a Day Lily).

other things, and, after all, furnish but poor and short-lived bloom, such as some of the Michaelmas Daisies and the Golden Rods, and a host of other plants that have been grown in gardens, the best way is to take them out to the shrubberies and ditches and let them take their chance.

When the plants are old and have got rather too thick, never hesitate to move them on a wet day in the middle of August or July, as well as in the middle of winter. Take them up and put a fresh bold group in fresh ground; they will have plenty of roots by the winter, and will flower much stronger the following spring han if they had been transplanted in spring or in winter.

Do not pay much attention to labelling; if a plant is not worth knowing it is not worth growing; let each good thing be so boldly and so well grown and placed that it impresses its individuality upon us.

Lilium speciosum Out-of-doors.—About twenty years ago a Lily bulb was planted in my garden in November; the person who planted it had little knowledge of Lilies, and believed that they were all hardy. The bulb in question was left, therefore, in the open garden to the mercy of the weather, which that winter proved to be very severe. Early in the following May, having ceased to remember the planting of this bulb, I was puzzled with the appear-

ance of a plant which had come up, and was showing foliage, which appeared to be strange to me. It was not long, however, before I saw that the plant was a Lily, and I then remembered the planting of it. Well, it grew most vigorously, and in due time—I think in the first week of September—the first bloom appeared, and when I saw it I was not a little surprised to find that my Lily was L. speciosum (lancifolium) roseum, which I had hitherto seen under glass only, coddled and petted as a tender plant, and not able to resist the rigours of a Scottish winter. After this my Lily received due attention, and the second bloom, that is, the bloom of the following year, and the vigour of the plant, convinced me that this Lily was hardy, and one of the finest of plants for the outdoor garden. From a single stem my plant increased year by year till the stems numbered about thirty, but by this time they had begun to grow weaker, and the blooms were growing smaller. It occurred to me that the soil was exhausted, so I resolved on seeing what was at the root, and in making the shift I found deep in the soil quite a nest of bulbs; I forget the number, but there were more than a dozen. They were separated and planted in fresh soil, and now I have bulbs by the hundred, and blooms of the greatest beauty by the thousand. So far as my experience goes, L. auratum is equally hardy, and has the advantage of blooming earlier; I had it in bloom in July, but the bulb was planted out early in spring. My garden rests on a porous rock which affords perfect drainage, and greatly helps to keep tender plants in the open air sound during winter.—R. C. R., *Ayrshire*.

Violets on Banks.—Violets are such universal favourites that any vacant spaces may be profitably planted with them by way of additions to the regular beds of them in kitchen gardens or forcing grounds. As a rule, we get the finest blossoms of both double and single varieties from one-year-old plants, raised annually from runners, and confined to single crowns after the manner in which Strawberries are prepared for forcing. It frequently, however, happens that there are warm sheltered banks under the partial shade of orchards and by woodland walks where, with good preparation previous to planting, Violets will flourish for years, and produce abundance of the finest blossoms with but little attention except that of keeping coarse weeds from overgrowing them. I have just planted such a bank under the shelter of a tall Hawthorn hedge; it was prepared as follows—the soil, being stiff and encroached on by roots, was deeply cultivated, and several loads of roads' scrapings and leaf-mould were added to it in the form of a top-dressing, sloping it gently to the south. In this the runners of Neapolitan, Double Blue, and the Czar (single blue) were planted 1 ft. apart each way, and kept watered until they had become well established. The Czar, being a vigorous kind, will probably overgrow the other sorts in time, but after four or five years' existence such banks will well repay replanting, and charming combinations may be formed by adding such roots and bulbs as those of Lily of the Valley, Squills, and other plants of like character that succeed under similar circumstances.—J. G. H.

The Three-leaved Gillenia (Gillenia trifoliata).—Lovers of hardy flowers who do not possess this plant should at once add it to their collection. It has numerous erect, slender, rigid stems, some 2 ft. in height, branching in their upper portion into a loose panicle of pure white flowers. This plant has a graceful, airy, distinct appearance, and when in full bloom forms a very pleasing object in the flower garden. When better known it will become a general favourite.—J. C., *Byfleet*.

Alstrœmeria aurantiaca.—This is one of the most effective species of this family of hardy perennials, and is worthy of more extensive patronage that it now receives. The flowers are of a bright orange-yellow, distinctly marked with black, and are produced continuously for a considerable period. For furnishing cut flowers the Alstrœmerias are valuable, but they should be planted in well-drained soil of a free warm nature, and should be well manured early in the summer.—J. C., *Byfleet*.

Snowdrops.—How much prettier these charming early spring flowers look when growing upon a carpet of green foliage than when left to look their best, or rather worst, upon the bare soil, let any one who may desire put to the test. I have just lifted all my bulbs and replanted them singly, not in clumps as before, working and cleaning the soil well, and adding a good dressing of road manure, dibbling in the tiny bulbs thickly all over, then adding a surfacing of fine soil, treading it over firmly, then raking and finally pricking in all over the surface a carpet of Sedum Lydium in one part, and of the Herniaria glabra in the other. These will make a bright surface of green during the winter, and then in the early spring the beautiful white Snowdrops will peep through, resembling gems bedecking a carpet of verdure.—A. D.

Violets by Post.—The season for Neapolitan and other Violets having again arrived, it may not be uninteresting to your readers to know that any one, though away from home, may enjoy them fresh every morning from October to May through the post. They are so well adapted for travelling, that a journey in a tin box of 200 or 300 miles does not in the least impair their sweetness or freshness. For Violets we have tin boxes made especially for passing through the post; they are 6 in. long, 2½ in. wide, and 2 in. deep. In these the blossoms are laid flat as they are gathered, between layers of Violet leaves pressed down tolerably

Type of the best Hardy Flowers—The Rocky Mountain Columbine (Aquilegia cœrulea).

close until quite full, when a layer of leaves is put on and the lid closed tightly down; the address may be pasted or written on the lid, and they may be relied on to reach their destination without being crushed, as they generally are, in cardboard boxes, and in fresher condition, as in tin they are cool and air-tight. Boxes of the size just named, when full, require three penny stamps, and hold several dozens of the finest blossoms. Boxes of this kind are equally serviceable for choice flowers, such as Gardenias, Rose-buds, Orchids, or Stephanotis; their size may be varied, according to the flowers intended to be sent in them, but I feel sure that any one at a distance from a garden, and receiving from home or their friends every morning a box of fresh Violets, will find it one of the by no means small advantages which the Post Office affords. I may add that Violets look best garnished with Violet leaves, but the leaves of the Neapolitan variety are not so effective as those of the single blue, such as The Czar and hardy Russian kinds.—J. G. H.

Hardy Cyclamens.—We are so much accustomed to see the bright flowers of the Persian Cyclamens in our greenhouses, that many never think of Cyclamens as hardy flowers. They are, however, excepting the Persian one, as hardy as Primroses; but they love the shelter and shade of low bushes or hill copses, where they may nestle and bloom in security. That they are hardy is not a reason why they should thrive in a bare exposed border. In such places as they naturally inhabit there is usually the friendly shelter of Grasses or branchlets about them, so that the large and handsome leaves are not so exposed that they are torn to pieces by wind or hail. Thus, for example, the Ivy-leaved Cyclamen is in full leaf throughout the winter and early spring, and for the sake of the beauty of the leaves alone it is desirable so to place the plants that they may be saved from injury. By acting on these considerations it is easy enough to naturalise the hardier kinds of Cyclamen in many parts of the country. Good drainage is necessary for the successful culture of Cyclamens in the open air. The species grow naturally among broken rocks and stones mixed with vegetable soil, grit, &c., and are therefore not liable to be surrounded by stagnant water. Mr. Atkins, of Painswick, who has paid much attention to the culture of Cyclamens, and has succeeded with them in a very remarkable degree, thinks that the tuber should in all cases be buried beneath the surface of the earth and not exposed, as in the case of the Persian Cyclamens grown in pots. His chief reason for this opinion is that in some species the roots issue from the upper surface of the tuber only. They enjoy plenty of moisture at the root at all seasons; they thrive best in a rich, friable, open soil, with plenty of well-decayed vegetable matter in it. They are all admirably adapted for the rock garden, enjoying warm, sheltered nooks, partial shade and shelter from dry, cutting winds. They may be grown on any aspect if the essential conditions above mentioned be secured for them, but an eastern or south-eastern aspect is best, always provided there is partial shade. We have seen them growing under trees among Grass, where they flowered profusely every year without attention.

ROSES.

Preparation of the Ground for Roses.—Supposing one is about to prepare a bed or border for Roses where the soil happens to be "stiffish loam," I thing it would be bad judgment to apply as manure any compound of an adhesive description; for such soil the manure ought to have a contrary tendency, and at the same time unite the necessary stimulating element—such substances as stable manure, sand, leaf-mould, and lime-rubbish incorporated, and allowed to remain for some months before using. On the other hand, for soil naturally poor and light the compound may be composed of cow manure, old night soil, and fresh stiff loam containing as much fibre as possible. These, with a liberal supply of liquid manure laid in a heap for a time, make splendid material for Roses when grown on light ground. In any soil the Rose is a greedy feeder, and demands annual manuring. In making a Rose garden, if the subsoil be at all stiff and retentive of water, it ought first to be properly drained, conveying the water to some distance by a main drain. Should the subsoil be sandy and gravelly, and drainage already exist—unless, as sometimes happens, there are springs which require to be drawn off artificially, thus preventing them from over-sopping the soil, in which case after draining and allowing time to draw off the superfluous damp—the ground may be well trenched, depositing at the bottom of the trench a good store of prepared compost, besides mixing the overlying body of soil with goodly portions of the same material; as the trenching process goes on heap the surface into deep rough ridges, and leave it in that state all the winter, that it may be properly pulverised by the united action of frost, wind, and rain. Again, in March, previous to planting, let the ground be partially trenched after a top-dressing of wood-ashes or burned clay should it be adhesive. Top-dress the light soil with the compost recommended as a suitable manure for its kind. The ground is now in readiness to receive the plants. Planting may be proceeded with; and as to the distance to place one plant from the other in the rows, that depends much upon the vigour or delicate nature of the respective kinds—some require 15 in. or less between, others as much as 3 ft. The habit of the plant should be understood as nearly as possible before its situation in the bed is fixed.—S. A.

Propagating Roses.—Two years ago I put in three rows of Rose cuttings of many varieties in October, and nine out of every ten made good plants the first year. During sharp weather I protected them by means of a little Fern.—G. R.

House and Window Gardening.

Insects on Window Plants.—The family of aphides supplies by far the greatest number of the pests which infest plants grown in rooms, and on account of their minuteness and remarkably rapid propagation they are very difficult to extirpate. The means both of preventing their devastations and also of extirpating them where they have established themselves, consist in good culture, cleanliness, fumigation, sprinkling or washing with various liquids, and dusting with good insecticide powders. By good culture, which includes ventilation at the proper time, and keeping the plants in a position not too warm nor too far from the light, the plants are enabled to form strong, healthy leaves, which are less liable to be attacked by such insects than if they were less favourably circumstanced. By attending to cleanliness all the decaying leaves will be removed on which the eggs and young of the insects often lie. When young shoots and leaves are much infested with them the best thing to do is to cut them off altogether and burn them, as when so attacked they, even when thoroughly cleansed from insects, are usually distorted or perish soon after. Plants from which they are to be removed should be shifted from among the other plants into a place where no others are near them. The stem-shoots and both sides of the leaves should be carefully brushed and then washed with warm water and a sponge to remove the "honeydew" with which the stems and leaves of such plants have become covered. If the infested plant be small, take three or four Laurel leaves, beat them all over with a hammer, so as to thoroughly bruise them; then place them round or under the plant and cover with a small bell-glass. Let all remain closed for a few hours, and the aphides will be found dead, each hanging by its proboscis only. If this process be repeated within a day or two to make sure, the plant will be perfectly freed, and in some cases it is not again attacked. This way of killing aphides may be acceptable to those who dislike Tobacco smoke; all danger arising from an overdose of it to a very tender plant is avoided; and the Laurel is so generally grown, it must be almost everywhere at hand for the purpose. The pot and the surface of the soil should in all cases be cleaned and thoroughly freed from all insects which may have fallen on them.

Mountain Ash Berries and their Uses.—I have frequently made excellent jelly from the berries of the Mountain Ash, or "rowans," as they are termed by the country people of Scotland. I have never observed there was much waste, but consider that the quantity of jelly produced is fairly proportionate to the quantity of berries used. The sugar required, however, is a half more than what is necessary for Black Currants; but of course the additional sugar gives additional jelly. The Mountain Ash jelly has a fine bright colour, and the flavour is not unlike marmalade; and it might well find a place on the table with any other home-made preserve. Last autumn, after making what jelly I required, I had a considerable quantity of berries left, and, being unable to dispose of them otherwise, they were thrown out in the garden, and covered in a heap of fine coal ashes, which were being collected from the house. This was in the middle of October. A day or two before Christmas a friend happened to mention how much she would appreciate a bunch or two of Mountain Ash berries for parlour decoration, but she had found it impossible to obtain them. I recollected my buried "rowans," and on removing some of the ashes I found the berries as fresh as when I put them there, and, with a slight rinsing in cold water, they were made as clean as when taken from the tree. My friend was delighted at receiving such a rare and unexpected addition to her floral devices; and while a portion of the berries was used in adorning her Christmas tree, the rest were devoted to the jelly-pan, and served at the Christmas feast.—J. C. McL.

Virginian Creeper for Shading Glasshouses.—In a villa garden near London I noticed the other day a novel as well as useful mode of shading glass structures during the summer months. The house in question has a circular roof, glass front, with a wall at the back. Outside, at one end, is growing a fine, vigorous Virginian Creeper, a strong shoot of which is trained along the wall, in a line with the roof, the whole length of the house. From this shoot or main rod other shoots are produced, about 1 ft. apart, which are trained perpendicularly down the roof to the front of the house. By this simple means an excellent natural shade is secured without the obstruction of so much light, as in the case of most shading material. When the foliage dies off in the autumn, the shoots can be cut back to within a few eyes of the main rod, and will start again into growth in the spring just at the time when shading is becoming necessary. This kind of shading is well worthy of adoption, on account of its handsome appearance, cheapness, and durability.—S.

FRUIT.

Keeping Apples from Shrivelling.—There is often a great loss arising from late Apples and Pears shrivelling after being gathered. Sometimes the cause may be gathering too early; in other cases the fruit room may be unsuitable for keeping late fruit; and there are some kinds of Apples, such as Court Pendu Plat, that will shrivel almost under any circumstances if managed in the ordinary manner. The best way of keeping late Apples that show a tendency to shrivel is to pack them in jars, boxes, or barrels, and strew dry sand amongst them, taking care, of course, that both in gathering from the trees and in packing no bruised or bird-pecked fruits are placed amongst that which is sound; they should be stored in a dry, cool place, and not disturbed until required for use.—H.

Type of the best Hardy Flowers.—Globe Flower (Trollius).

Doyenne Boussock Pear.—This excellent variety should not be overlooked by any one who possesses a dozen Pear trees, and who intends now to add to their number. It has to recommend it four very desirable peculiarities—size, appearance, flavour, and productiveness. With regard to the first and last, I may mention that I have just taken from one stalk three, the combined weight of which amounted to 1½ lb., and all three were nearly of equal weight; and as to the second, not only is the fruit handsome, but the foliage often becomes a deep red before the leaves fall. My tree, for I have only one of this variety, is on Quince roots, and is trained on a wall facing due west. I have never known it fail even in bad seasons. Orders for fruit trees should be sent without delay if they are to be planted to the greatest advantage.—B. S.

Keeping Late Grapes.—Many people are deterred from adopting the very useful plan of keeping late Grapes in bottles of water from the idea that some elaborately fitted up or air-tight compartment is necessary; but this is by no means the case, as, with a little contrivance, a good Grape room may be extemporised in any compartment inclosed with four brick walls. The principal point is to get a steady temperature, that would not be liable to sudden fluctuations; and for this reason a room with a northern aspect is desirable, or, what is better still, an apartment that does not communicate directly with the outside air. The advantage of having the Grapes thus securely bottled when severe frosts and sunshine render it impossible to maintain the houses in which they were grown at anything like an equable temperature after the beginning of the year can only be fully realised by those who have had to keep them on the Vines until late in spring, besides the benefit which the Vines derive by being released of their crop and pruned, cleaned, &c., at the most favourable period. The keeping of Grapes successfully in bottles of water is now well known; but any doubtful of its advantage should try it first on a small scale, and I feel sure they will soon adopt it fully and without reserve, as I am confident Grapes keep better when cut than when on the Vines after the commencement of the year.—J. G. L.

Rust on Grapes.—Having read with much interest the opinion expressed by the two different correspondents as to the cause of rust on Grapes, I thought it would not be out of place to give a few causes as to the evil of rust on Grapes, and at the same time show how the evil may be overcome. I have already six different causes which produce rust, and having given a great deal of time to the cultivation of the Vine, I do not think but that rust on Grapes might never more be seen if the following causes were avoided: 1. Injudicious application of the scissors in thinning. 2. The hair of the head coming in contact with the bunches. 3. Syringing the berries with hard water. Some years ago at Welbeck our supply of soft water became exhausted, as a consequence we had to use water from the mains, and the result was plenty of rust on the Grapes we syringed. I have had two cases brought under my notice this summer, and each case has been from syringing with water from the street mains. 4. In the early part of the season syringing with water much below the temperature of the house. 5. Avoid thrips and ants. 6. Steam arising from manure water, which causes rust to set in wherever the least steam touches a berry. Different opinions have been expressed on the matter, but I believe that the above are the main causes of the rust on the Grape.—T. Lowe, *Penketh.*

Carnivorous Insects.—The insect from the description of "H. H." was the larva or maggot of one of the sun-flies common in most gardens. The larvæ of these flies feed on the aphides, some being partial to the green, some to the black fly. I have taken the larvæ from the Rose, Cherry, and Thistle, and reared the flies from them. I don't think they would prove very efficacious in a house, but a trial

might be soon made if the animal was about when required. Perhaps two or three dozen of the flies might be introduced with effect. In such a case, however, a failure might not be conclusive, no more than in the case I will mention. In GARDENING of September 18 a correspondent writes that young ducks will devour the caterpillars from the Gooseberry and Currant bushes. My experience is different; two or three batches have been accustomed to roam the garden and pick worms from the newly turned soil; they soon knew a spade or fork from any other tool. Thinking to utilise them as your correspondent advises, I tried them with the grub repeatedly; seldom would they touch one, never a second. I shall try again next year.—V.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

October 11.—Potting young Pelargoniums; planting Arabis in flower-beds; taking up Schizostylis and planting it in cold frames; tying Endive; pruning and nailing on north sides of walls; putting Chrysanthemums into span-roofed Peach houses; getting East Lothian Stocks under cover; taking up Lettuces and putting them into orchard house; laying Lilies in pots on their sides and covering them with sand; laying Box; gathering Yew berries for sowing; beginning to manure garden ready for digging; preparing manure for next year's Celery; pruning and nailing Cotoneaster; cleaning Endive that has been planted for protection near walls; keeping Roses in pits at about 55° by night; giving Pelargoniums a little heat if cold or wet.

Oct. 12.—Potting young small-leaved sorts of scented Pelargoniums; planting hardy flowers and bulbs in beds on terrace; also more Lettuce for spring use; taking up some Peach trees and replanting them, in order to check over-luxuriance; putting all tender cuttings into pits, leaving those that are hardy in frames; getting Strawberry plants and Anne Boleyn Pinks into frames; putting Fuchsias and scented Verbenas under greenhouse stage; also Coleus and Iresines into Cucumber pit; gathering all the late sorts of Pears and Apples; gathering Tomatoes and putting them on Vinery flue; finishing mowing.

Oct. 13.—Putting in cuttings of Pentstemons in cold frames, also of Pansies, and of a few more Hydrangeas, placing the latter in a Cucumber pit; clearing verandah and planting its border with Wallflowers, bulbs, and other plants; taking up Cinerarias with large balls, putting them into large pots, and placing them in a cold pit; putting Endive from open ground under the protection of walls; taking up Carrots, and stacking them and Beetroot, having first dried them; earthing-up Leeks; cleaning Vines in early Vinery, and painting woodwork; weeding young Onions and Spinach; storing all bedding plant boxes in shed.

Oct. 14.—Potting some more Narcissus showing flower; planting Wellingtonia and Abies Douglasi; laying in a quantity of hearted Cauliflowers in pits; putting a few Heliotropes into a little warmth to induce them to open their blossoms; putting some long straw around Violet frames; washing Camellias and Oranges; looking over Mignonette for caterpillars; salting walks; putting fresh soil to standard Morello Cherries; digging vacant ground; rolling walks; weeding Lily of the Valley.

Oct. 15.—Potting Anemone japonica and some plants of Sedum spectabile; also Lily of the Valley; planting fruit trees; tying up some Bath Cos Lettuce; getting Violets in pots under cover, also Stocks and Centaureas; bringing Maréchal Niel Roses under cover; stacking Strawberry plants in pots for which there is no room in frames; sponging Daphnes and Stephanotis; suspending ropes of Onions in loft; top-dressing tree Mignonette with manure; pruning first Hamburgh Vines; keeping flowering Pelargoniums about 50° at night; thinning buds on Camellias.

Oct. 16.—Potting Dielytra and Hoteia japonica; also Veronica Andersoni from borders and Centaureas, and putting the latter into slight heat, taking off nearly all the leaves; taking off Chrysanthemum layers; plunging Roses, after pruning them, and double Wallflowers in a cold pit; nailing Currant trees on walls; getting all Pelargoniums under cover; taking up all Endive from the open ground; gathering seed of Scarlet Runners; putting frames ready for Lettuce; giving Cherries fresh soil; spawning second Mushroom bed; earthing up July-sown Cabbage; plants in flower in conservatory—scented, scarlet, pink, and double Pelargoniums, Stocks, Mignonette, Balsams, Fuchsias, Heliotropes, scented Verbenas, Amarantus, Coleus, Lobelias, Chrysanthemums, Primulas, Petunias, Larkspurs, Justicias, Narcissus, Scutellarias.

Glasshouses.

Mignonette for Winter and Spring Flowering.—Where the cultivation of Mignonette is made a special feature, the plants raised from seed early enough to give time for their attaining a good size should now be accommodated with a good position in a light pit or house and placed close to the glass, so that they can receive plenty of air, for on this, in a great measure, depends their leaves having sufficient strength and substance to keep green and healthy during the winter; the plants sown late in the summer, and again about the beginning of September, will need to be kept quite cool. A light, airy pit or cold frame with the lights drawn completely off on fine days is the best position for this late stock, as the object is not to bring them on quickly, but rather to keep them short and sturdy until the winter is far advanced, when, through the increased light, they will naturally make more growth, and come into flower and last until the spring-sown plants are ready to succeed them. One essential in the pot culture of Mignonette is to keep the plants scrupulously clean from aphides that establish themselves on the undersides of the leaves, and if not sought for, they frequently, before being noticed, weaken the foliage, so as to cause its premature decay. Diluted manure water should be given every week to the most advanced plants.

Schizanthus.—Though somewhat common plants, there are few amongst the many more pretentious subjects that can be made to produce a better display in the conservatory or greenhouse during the spring when well managed. If liberally treated they will attain a size seldom seen amongst the generally crowded examples grown out-of-doors. The quantity of flowers they will produce will of course be proportionate to the size of the plants, which will be best regulated by the size of the structures they are required to embellish. To grow them to a large size the pots will need to be 12 in. or 13 in. in diameter, and any plants that are suffering for want of room may be at once transferred to pots this size; for if allowed to remain long in the small-sized pots after the roots get crowded, the repotting later on will have little effect in benefiting the plants. The soil should be such as is calculated to grow Pelargoniums well—containing a good quantity of manure. Similar treatment in other respects to that advised for Mignonette will answer for these also.

Pelargoniums.—Plants of the large-flowered kinds that were kept on blooming beyond their usual time, and were cut down late, will have broken sufficiently to admit of the old soil being removed and the plants repotted, potting them, as in the case of those previously cut down, in smaller pots, in which they can remain until after Christmas. These plants will last for a number of years, and by treating them in the manner advised the earliest portion will come into flower sooner in the spring, and the latest will acquire the habit of regularly flowering late, by which they meet the requirements of those who grow them for general decorative purposes, and whose object is to keep up a display over as long a period as possible. The first and second potted plants will now have begun to root freely, and may receive a little more water, but care must be taken from now and throughout the winter months that the soil is only kept in a sort of half-moistened condition, that is, much drier than the majority of other plants would be kept. It is necessary to impress this upon those who have not had much experience with this section of Pelargoniums; for if the soil be kept as moist during the winter as most other plants in a growing state would need, the result is that the roots make little or no progress whatever, and the shoots that are made would be long-jointed and weak, which would produce leaves so deficient in substance that they would turn yellow and prematurely die away, leaving the plants when the flowering season arrives thin and naked at the bottom. Those first potted should, as soon as they require it, have a few sticks put to them, so as to admit of the shoots being tied out in a way that will keep the centres of the plants open; for, though it would be a mistake to train plants required only for ordinary decorative purposes to the extent necessary for those that have to be moved about for exhibition, still, to grow Pelargoniums in a way that will preserve their natural habit, the plants must be kept sufficiently open to preserve a sturdy habit.

Fuchsias.—Plants that were struck at the end of July and afterwards placed in small pots should not be allowed to remain in these too long, for if once they get into a stunted condition they will never grow freely afterwards. They should now be placed in 5-in. or 6-in. pots, which will be large enough for the winter, potting them in good loam, well enriched with rotten manure, with the addition of enough sand to make the whole sufficiently porous, but not too light. They should, if possible, be kept on a shelf close to the roof in a warm greenhouse. Tobacco smoke is injurious to the leaves of young Fuchsias such as these, especially during autumn and winter; but if aphides make their appearance, the plants should be dipped in Tobacco water. These young plants will make much better specimens than old plants; but where provision has not been made by striking them at the time these were put in there is no alternative but to use the old plants again next year, for which purpose those that flowered first during the past spring should now be put to rest. Take those that flowered earliest in the spring and from the present time gradually reduce the quantity of water applied to them until there is but little further disposition to grow, and then cut the side branches close in, and reduce their height so far as is considered necessary. The plants should be placed as closely as possible in any house or pit where they will be secure from frost, and merely giving them water enough to cause the buds to break, but not more than will maintain them in a half dormant condition until after the turn of the days. Plants that were treated so as to bloom late throughout the autumn, if well furnished with advancing buds, as they should be, will keep on flowering for some weeks, and though the display they make is not equal to that produced earlier, yet when flowers are scarce they will be found useful.

Bulbs.—It is now quite time to see about potting the general collection of such bulbs as are required for winter and spring flowering, especially Hyacinths, which, in common with all other plants of a similar nature, evince by their roots beginning to develop that they want to be placed in soil. In the growth of these plants, and particularly Hyacinths, there is no necessity for using pots so large as are often employed. The splendid spikes which the London market growers produce with two or three bulbs put in a small pot only just sufficient to admit them is sufficient evidence that a great deal more depends upon the condition and strength the roots have acquired previous to the time of their being forced than on any assistance that can be derived from a large amount of root space. In selecting Hyacinths amateurs should rely upon the good and well proved older varieties. Though Hyacinths are such general favourites, their comparative uselessness after the first season's blooming makes them much dearer than most other bulbs. The Polyanthus Narcissi have not this objection, for after being flowered in pots they can be planted out in the open borders, where they will make a fine display in succeeding years; the agreeable perfume and form of their flowers especially adapts them for cut purposes. Similarly in subsequent seasons Tulips flower well, and many of the fine single-flowered varieties deserve to be much more largely grown in pots than they are. Crocuses, especially such kinds as Queen Victoria (white), Sir Walter Scott (pencilled lilac), Pride of Albion (white, striped violet), Mont Blanc (white), and New Golden Yellow are very beautiful, and most useful where grown in sufficient quantities so as to keep up a succession. If their wants are attended to after blooming they will, in future years, be equally as effective out-of-doors, and much superior to the commoner kinds more generally used for planting in borders.

Squills (Scillas), particularly S. sibirica, can hardly be too largely grown in pots, in which there is no difficulty in getting them to bloom freely. The charming shade of blue and elegant manner in which the flowers are produced especially adapts them for bouquets. When grown in sufficient quantities they will be found most serviceable, particularly in severe winters, for a continuous supply until those in the open borders flower; ordinary sandy loam suits all the above kinds of bulbs admirably, and the pots should be well drained. As to treatment after potting, nothing answers the essential object of getting a plentiful supply of roots before much top-growth is made better than the old-fashioned method of plunging them in a bed of coal ashes out-of-doors with 4 in. or 5 in. of the same material underneath the pots in order to keep out worms, and 6 in. above. In five or six weeks they will generally have made plenty of roots.

Ixias and Sparaxis.—These beautiful plants are fine objects in pots, their rich and varied colours, together with the graceful habit of their flower-spikes, are such that no doubt they would be much more cultivated in this way if they were better known, though most of

them are old introductions. Six-inch pots are large enough for half-a-dozen bulbs of these; but after potting they should be placed in a cold frame, so as not to be so much exposed to the wet in the way that Hyacinths and other similar bulbs would be, as they do not like as much moisture until they have got plenty of roots.

Tritonias.—These are amongst the most useful greenhouse decorative subjects we have, as they may be had in bloom from early in the season until the summer is far advanced, when greenhouse flowering plants are comparatively carce; but though thus not coming under the head of forced flowers, it is well for those who think of growing them to obtain them at once and pot them. Those who are acquainted with the old well-known orange kind (T. crocata) may form some idea of the effect that may be produced by growing an assortment of the blush, scarlet, white, and shaded varieties. A dozen bulbs grown together in 7-in. or 8-in. pots will be found a very useful size; where larger specimens are needed, all that is requisite is to have larger pots containing a proportionately larger number of bulbs.

Flower Garden.

Carnations and Picotees.—All who are growing collections of these will now be busy amongst them, removing and potting the layers, or planting them out in beds of fine soil to be afterwards transplanted. Each layer must be carefully raised out of the ground. If roots have been formed the plant may be cut off; if not, press it into the ground again to remain until roots appear. If it be intended to plant out into the open ground, the beds should be prepared for them by being deeply trenched, and, if necessary, some rotten stable manure should also be worked into the ground, but it ought not to be nearer the surface than 6 in. Clumps of the commoner border varieties are much appreciated when placed near the front of herbaceous borders. The best way to manage them is to layer the shoots in the manner as recommended for the choicer varieties, and allow the plants to remain where they are layered. Good rich sandy loam and manure should be placed round the roots. Such clumps as these produce scores of blooms during the season.

Dahlias.—The fine weather suits these, and we are still getting masses of very fine blooms. There is no further attention required than to tie the stems to the sticks, and allow the plants to produce as many flowers as they will. Such flowers are very useful for cutting, and if they do not attain the size of exhibition blooms they are none the less useful for room decoration. The single-flowered kinds, such as D. coccinea, lutea, and Paragon, ought to be grown more than they are. The plants may be carefully lifted at the first signs of frost, and taken into a Vinery from which the Grapes have been cut, or a similar place, where they will continue to produce flowers for several weeks.

Gladioli.—If the spikes of these are cut just as the first two or three blooms expand the others will open indoors if placed in water to the top of the stem. If there are any seed-pods ripening they should be gathered just as they begin to burst. Lay them on paper in a dry, airy place, where they will open in a few days and the seeds fall out. A green caterpillar is at present busy in eating the flower-buds before they appear out of the sheath; these should be at once sought for and destroyed.

Pinks.—No time should now be lost in planting these in flowering beds. The plants should be carefully lifted and a hole dug out for their reception large enough to contain half a spadeful of good loam and manure; place this compost carefully round the roots. The plants should be 9 in. apart each way. A few of the best named Pinks are Blondin, Bertram, Boiard, Cristabel, Device, Dr. McLean, Dr. Masters, Emerald, Emily, Excelsior, Freedom, Godfrey, Harry Hooper, John Ball, Lady Craven, Mildred, Mrs. Mitchell, President, Reliance, Shirley Hibberd, and Victory. In making up a collection such sorts also as the following should not be omitted: Lord Lyons, rosy-purple; Lady Blanche, pure white; Anne Boleyn, Derby Day, and Mrs. Pettifer. These are quite distinct in type from the florists' section, and are much valued as cut flowers.

Pentstemons.—These are still flowering most freely; the stems from each plant are numerous and quite loaded with flowers. All the attention they require is to see that the stems are supported with sticks, but where they are planted in beds the stems support each other. The seed-pods must be removed, as they tend to check the production of flowers. Cuttings must now be put in. There are always plenty to be obtained at this season; the small side shoots at the base of the stems are best. Insert the cuttings in pots or boxes of fine sandy soil, and place in cold frames or handlights, as may be most convenient. Shade them from the sun, and water them moderately.

Herbaceous Borders.—These should now be carefully looked over, removing all decayed stems and leaves which would otherwise give shelter for insects and other pests, and every possible means should be taken to destroy them—such as hand-picking and spreading lime, soot, &c., over the surface of the ground. If these precautions are neglected many valuable plants must inevitably suffer from their depredations. A clean cut is most essential in everything connected with pruning, so it is important that a sharp knife should be used for cutting away the woody stems, or much damage may result to the stools of some kinds in consequence of the loosening of the roots and splitting the stems. The soil must be carefully forked between the plants and all vacancies made good by dividing old stools, &c. Pansies, Daisies, Arabises, Aubrietias, and such-like spring flowering plants should be put out at once, so that they may establish themselves before severe weather sets in. Bulbs of various kinds should also be planted in the most open spots, placing a thin layer of silver sand beneath them to prevent rotting and accelerate the formation of roots. For this purpose Hyacinths, Tulips, and similar kinds which flowered last spring will be found extremely useful if they have been properly treated and stored. They should be planted in clumps of six, eight, or ten, and from 2 in. to 3 in. apart; a small stick should be placed in the centre to prevent injury when digging or stepping on the borders, and as a guide when mulching them for protection during the winter, if necessary. Herbaceous plants, it must be remembered, do not ripen their stems and foliage simultaneously, therefore only those whose stems are ripened should be cut down, as many kinds would be thus injured if they contain active sap.

Shrubbery.—Strange to say, many still persist in planting such evergreen trees, shrubs, and Conifers which have not the slightest chance of thriving; they are therefore unsightly, and a continuous source of trouble and expense. In places where planting is scanty, the bare ground is always an eyesore. A shrubbery should be formed by various kinds of plants, with the foliage harmoniously blended, and planted sufficiently wide apart so as to obviate overcrowding. From time to time they should be pruned or even taken away where it is desirable. Where specimen plants are required they should be planted singly, as the shrubbery is certainly not the place for them. As it is useless in towns to plant varieties that are quite unsuitable, it is far better to plant those possessing qualities that render them capable of thriving in smoky districts, though they may not be the handsomest. Amongst the best shrubs for such positions are undoubtedly the Privet, Euonymus, and Aucuba. Of Privets there are several varieties which can be recommended, such as the oval-leaved, the Japanese, the evergreen, the Box-leaved, &c. Of Euonymuses there are also several kinds which may with safety be planted, the green-leaved varieties being the best and strongest. All these, as well as the Privets, naturally form pretty shrubs, and should not be clipped into all kinds of shapes, but allowed to grow freely. The Aucuba is too well known to need description. In wet seasons when the foliage is kept in a fairly clean condition, the leaves of these shrubs present a fine lustrous appearance. The varieties of Forsythia and Rhamnus will also do well in town gardens. The broad-leaved kind of the latter grows into large specimens in a very few years. The Rose of Sharon (Hypericum calycinum) is a well known and excellent shrub for forming undergrowth, and for planting on the borders of plantations, &c. Amongst deciduous shrubs the varieties of Ribes are perhaps the best, and should always be included in the list. The Sumachs, too, are very useful for such places. The planting season being near, a trial of these shrubs may be made, allowing one shrub to the square yard at least. In all small gardens there should be facilities for washing the foliage of shrubs when necessary. After planting, the surface of the soil should be covered to a depth of about 2 in. with well-rotted manure or horse droppings mixed with road scrapings in equal proportions; the latter collected off flint-metalled roads is the best for the purpose.

Vegetables.

The earthing up of all the Cabbage tribe that are large enough for the operation should be done at once for the sake of protection from the effects of the wind, and also for the free action of the air to the land; any other benefit derived from such a practice is of a doubtful nature, and if it were not necessary for the reasons above given, the earthing-up system had better be abandoned. Celery requires attention as to earthing, and should be tied with bast previous to the operation, in order to prevent the soil getting into the centres of the plants. The Celery-fly is prevalent this season, and we find a sprinkling of soot applied once weekly an effective antidote, for though it does not destroy the pest outright, it hinders the spread of it. Cauliflowers that are now turning in will need daily attention to keep them from injury by frost; break the leaves over the flowers, or, if a quantity be ready for use, and it is found necessary to prolong the supply, take them up with the entire stems, and hang them in a cool shed, head downwards; in such a position they will often keep for six weeks. Lettuce, Endive, and herbs for winter use all demand particular attention at the present time, so that there may be no scarcity when required. Protection should be in readiness, as frosts may now occur any night. Tomatoes not yet ripe, and that are of a size large enough to be used, should be cut, and, if hung in a warm, airy house, will ripen perfectly. The storing of Beetroots and Carrots will soon be necessary. As a rule we winter them in the ground, and use Bracken or straw for protection, and by this method the roots are more tender than when pulled up and stored in sand. Look over the stores of Potatoes and Onions in wet weather. The latter will keep best if bunched and hung up rather than laid on shelves. Rhubarb and Seakale will soon demand attention. Give abundant ventilation to French Beans in pits, and from now all the sowings will do best in pots; to keep up a continuous supply it is necessary to sow a batch fortnightly. Tomatoes that are fruiting indoors should have the growths kept thin and the fruit also; they may then be expected to continue in fruit throughout the winter.

Winter Onions.—Where there is an inclination to grow these as large as they are capable of becoming, a piece of ground should now be deeply dug and heavily manured, getting the manure well down to the bottom of the trench, say 15 in. or 18 in. deep, and on this some of the autumn-sown Onions should at once be planted; they must be carefully lifted with a planting trowel, so as to retain all their roots uninjured; for planting use either the trowel or an ordinary dibber, but whichever is employed see that the fibres are not doubled up, but put in straight down in their natural position; plant them in rows 1 ft. apart, and 4 in. or 5 in. asunder in the rows; this will admit of every other being drawn for use in the spring, allowing the remainder to grow to their full size. I have tried both autumn and spring planting with this crop, and find that the present is much the best, the roots attaining a larger size when moved at this time than in the spring, when they are making more active growth; another advantage is that the check which they now receive has the effect of rendering them hardier and better able to stand a severe winter, should such occur, than those that are allowed to remain in the seed bed.—B.

Endive for Autumn and Winter Use.—In wet seasons tying up Endive is of little use, as it is sure to become rotten at the heart before it is sufficiently blanched. To prevent this I find it a good plan to double in the outer leaves and place a clean blue slate on the top of each plant; the slate is less likely to harbour slugs or vermin than wood. If the plants be on a sloping border so much the better, as the slates will throw off the rain, blanch the Endive beautifully, and make it more crisp than if tied up. Another good plan, in the case

of late Endive, is to take it up with a good ball of earth and well tie in the leaves, selecting a dry day for the operation; then pack the roots in mould in a light open shed, or, better still, at the foot of a south wall, letting the roots into the ground; then place an inclining board over them. This will make them white and preserve them a long time. Endive, thus treated, will have white hearts larger than a man's fist, and these, with a little Mustard and Australian Cress, which can easily be obtained at all times, make a good salad in autumn and winter, when Lettuces and other things are scarce.—C. H., *Oxon.*

GLASSHOUSES & FRAMES.

Habrothamnus elegans.—Some say that plants of this Habrothamnus are only suitable for pillars and walls; also that they should not be stopped until after the flowering season, when they can be cut hard back; but I prefer small plants for autumn use to using them as climbers, also that they should be stopped for this purpose, as it causes them to flower earlier, and keeps them in good shape for the conservatory, greenhouse, or table. Like many more, I did not value this plant in a small state until my attention was especially directed to it in that condition. I then took about a dozen healthy shoots, with a heel attached to them, off an old plant, which was neither useful nor ornamental; these I struck in the usual way, and I potted them in June in 5-in. pots, and grew them on near the glass in a warm greenhouse, stopping them frequently until some time in July or August, when I removed them to a cooler temperature, where they soon showed signs of flowering. They blossomed freely, and, from the commencement of the flowering period up to the present time, they have not ceased to form striking objects, and they still look as if they would keep in bloom for some time to come. It is therefore clear that if this plant be grown properly in 5-in. pots, or in any other size required, it will become both useful and ornamental at this season of the year, when it is difficult to keep conservatories well supplied with flowering plants. I am also of opinion that if it be kept in good shape and healthy it will make a valuable table plant, both as regards duration of bloom and also brightness of colour under gas or other artificial light.—C.

Wintering Calceolarias.—As the best season for propagating these has now arrived, let me recommend those who have hitherto experienced any difficulty in keeping their plants healthy through the winter to look well to the quarters in which they are placed. They cannot bear artificial heat, and therefore a cold frame is the best for them; set it on a hard foundation of coal ashes, and spread over the ashes 6 in. of good fresh soil, consisting of sandy loam and a little leaf-mould; beat all down firmly, and insert healthy cuttings from growing shoots 4 in. apart each way. Water freely, and keep the frame close until the cuttings are rooted, after which ventilate freely on all favourable occasions, and water when necessary, as drought is injurious to Calceolarias of this class. Pinch out the points as soon as they commence to grow, and by April they will be fit for planting in beds. The roots being in a solid mass will move in square blocks by cutting down between each plant, whereas plants in loose soil will not recover the check sustained by transplanting for some time.—J. G.

Roseate Maiden-hair Fern (Adiantum rubellum).—Most Ferns are remarkable for their fresh greenness, but several of the Maiden-hair kinds are delicately tinted with dark rose or rosy-purple. A. rubellum is one of the most ornamental in this respect, its delicate fronds being richly tinted with a roseate hue, which is all the more apparent when contrasted with other forms of the British Maiden-hair (Capillus-veneris) section to which it belongs. As will be seen by the accompanying illustration, the plant is dwarf and compact in habit; and its elegantly tinted fronds, which are produced in abundance, vary from 6 in. to 8 in. in length. It is a native of Peru, and was introduced several years ago by Messrs. Veitch & Sons, of Chelsea. It grows well in a cool Fernery, or anywhere where there is a very moderate temperature. Its culture is as easy as that of other Maiden-hair Ferns, and should be treated to fresh fibrous peat and sand, together with a moderately humid atmosphere, and a liberal supply of moisture at the root, when growing.

ANSWERS TO QUERIES.

3215.—**Climbing Red Tropæolum.**—Probably "Heather" refers to the Flame Nasturtium, so called Tropæolum speciosum, which is usually treated as a hardy herbaceous plant, the roots remaining in the ground all the winter where it is dry and fairly sheltered, although, perhaps, safest lifted and stored for the winter if the soil be cold and subject to intense frost. An excellent place for this Tropæolum is amidst low-growing shrubs, where in the summer the growth covered with rich scarlet flowers can run at will over the tops of the shrubs, and decorate the green foliage with brilliant hues. In other places the plants do well at the base of a south wall where it is warm and sunny, but the fact that it thrives so well in the north rather shows that a cool situation will suit it well. Propably one of the chief desideratums for it is a deep, cool, sandy soil, and some little added protection for the roots in the winter. There is no reason why it should not do well in Somersetshire.—A.

3121.—**Annuals for Profit.**—A good bed of the double Indian Pinks would be of the greatest value to cut from for bouquets. These may be sown now or early in the spring. Various hardy annuals, such as white and carmine Candytufts, Mignonette, not gay of colour, but ever acceptable for a nosegay; Scabious in several colours, the blue, yellow, and purple Centaurea, or Cornbottle, the blue a lovely thing, and the yellow or Sweet Sultan, one of the most charming of all yellow flowers for cut uses. Ageratums are tender, but of the utmost value as cut flowers, the colour of the flowers chaste and pleasing, and stems long and stout; Globe Amarantus, the flowers of a pretty purple hue are very showy. Rhodanthe Manglesi is a charming plant, the flowers rosy-pink in colour; and Helichrysums are not only very varied, but furnish an immense quantity of bloom. Phlox Drummondi is not strictly hardy, but it is a capital summer annual, and furnishes a number of flowers for cutting. Asters also are exceedingly valuable as cut flowers, and whilst the large blooms are best suited for nosegays, the small side flowers may be used almost for any purpose. The Myosotis is not an annual, but is quite charming for button-hole purposes; perhaps there is nothing prettier with a white Pink or Carnation and a spray of Fern than a piece or two of the Myosotis, or Forget-me-not. Especially pretty for pot culture under glass are the bright red and yellow Celosias, or feathered Cockscombs. These are all very elegant and beautiful, the side shoots supplying most desirable button-hole material. The Bartonia aurea gives a bright yellow colour in small flowers, and the Erysimum a deep orange hue. There are few of these things that are not best grown in the open air, but some if sown in the autumn in pots will bloom early, and if sown in August will bloom late under glass.—A. D.

3190.—**How to Collect Lobelia Seed, &c.**—The usual way to collect seed of Lobelia is to cut the plants off close to the ground, spread the cut portion on a sheet of paper and lay it in the sun until ripe; then rub out, clean it, and put it away until the time to sow next March. Balsam seed is gathered now or when ripe. Watch the pods, and when they become yellow gather carefully and put them into a paper bag. Rub the seed out after all is gathered, dry it, and keep until April; then sow under glass. Perilla is always sown in pans or pots under glass in April, and is better for a gentle heat, as it is a tender plant. Seed of this is usually imported, and we think it is doubtful whether you can save any. If the Phloxes named are of the annual or Drummondi section the seed-pods should be picked off as soon as they become brown, and put into a paper bag. This should be sown in a frame or greenhouse in the month of April, as it is a tender annual.

3185.—**Seedling Calceolarias.**—The proper season for the herbaceous Calceolaria to bloom is the months of May and June. Shrubby kinds bloom all through the summer. Yours are probably herbaceous and tender. You will find very considerable difficulty in keeping these in a room without their being very much drawn, and becoming exceedingly gawky. You must keep them close to the light, give all possible air, and watch well for aphis, by which the plants are soon infested if the atmosphere becomes dry. The plants must be often turned to allow the light to play on all sides. The proper place for them is a cold frame till Christmas, and after that they should go into a greenhouse. The best soil is composed of one-half nice turfy loam, and the rest of well-decayed manure, leaf-soil, and sand, all well mixed. We fear that these herbaceous Calceolarias will prove to be very unsatisfactory window or room plants.—A. D.

3109.—**Keeping Potatoes.**—There should not be any difficulty in keeping Magnum Bonum and other late Potatoes until the end of May if stored in any dry and moderately cool place. Late Potatoes if kept where the air is dry will not begin to spring at the eyes until April, and then if once looked over and the shoots rubbed clean off, will hardly require further attention before the end of May. We give the preference for convenience and space to storing in disused flour barrels, as whilst the bulk may seem great the open tops permit all perspiration or sweating exudation to escape freely. Further, if there are several barrels full the contents can be emptied one at a time, be picked over, and replaced. A cool, dry room, a dry cellar, or even an outhouse will make excellent stores if frost is excluded.

3120.—**Fuchsia Buds Dropping.**—Your complaint of Fuchsia buds dropping is a very common one, and invariably arises from the dry and unhealthy condition of the atmosphere in which the plants are kept. Fuchsias if well watered and not too freely exposed to scorching sunshine will bloom abundantly on a window-sill, but inside the window will drop all its blooms ere they expand. This simple fact shows that although plants may in both cases suffer from being pot-bound, yet where the plants are exposed to the cool external air that is no serious evil, whilst inside, and in combination with a dry atmosphere, it is a serious one. If the plants are in a room give, if possible, more air and light, and whilst the plants are still growing, water freely, and see that the roots do not become dry at the bottom, though perhaps moist enough at the top.—A. D.

3193.—**Striking Cuttings without a Greenhouse.**—If your window space is limited you would do wisely to allow your cuttings to remain in the cutting pots until March, but if you have ample room, and the cuttings are well rooted, then pot off at once in small pots singly, as in these they will sooner get established than in larger ones, and you can give them a shift into such in the spring. If potted now with poor roots the plants may soon damp off and die. The season is now almost past when active growth takes place, and if they make no growth between potting and the winter no good can result from the performance of the operation now. Give all possible air when there is no frost and the wind is not strong or cold; the more the plants are hardened by exposure the better will they stand the winter.

3214.—**Window Plants.**—We should certainly advise for a winter window-box a few nice, ornamental dwarf shrubs or little Conifers, assuming of course that the box is to be outside the window, and not within. Some three or four of these might have a carpet of Myosotis, double Daisies, Arabis, Aubrietia, &c., or it may be filled with blood-red Wallflowers and a carpet of blue Nemophila or white Arabis, or of a few good plants of white Iberis corifolia carpeted with purple Aubrietia, or planted with Hyacinths or Tulips and Snowdrops, and carpeted with a green Sedum. All or any one of these combinations would look very nice. Such things as Pansies mixed look pretty in a window, but for winter decoration the shrubs are best.—A. D.

3176.—**Conservatory Plants.**—The first thing to do is to make a good border for the permanent plants. The excavation should not be less than 3 ft. deep, in order to give space for drainage and soil. The drainage may consist of broken bricks or stones, and should be 8 in. or 9 in. in thickness, filling up the remainder of the space with good turfy loam and peat in about equal portions; crushed charcoal and sand may be added to insure porosity. If

a tropical character is to be given to the interior of the house, then Palms and tree Ferns should be used; but I think flowering plants, such as will bear the knife when they become large, will be more satisfactory in so small a house. The following flowering plants will be suitable for planting out: Camellias, Luculia gratissima, Rogiera gratissima, Acacia longifolia magnifica, A. armata, Cytisus racemosus, Daphne hybrida, Grevillea elegans, Habrothamnus elegans, Linum trigynum, Nerium album plenum, Plumbago capensis, Polygala Dalmasiana, and Veronica Andersoni. A few foliaged plants might be added, such as Dracæna indivisa, D. rubra, and Ficus elastica, but I have generally found flowering plants prove the most satisfactory. Fuchsias will do beautifully planted out in such a house; Mignonette would grow into a tree lasting for years, as would also Heliotropes. The climbers may be selected from the following: Bignonia Cherere, Clematis lanuginosa pallida, Cobæa scandens variegata, Hardenbergia monophylla, Jasminum Poiteau, Lapageria rosea, L. rosea alba, Mandevilla suaveolens, Passiflora Colvilli, P. Newmani, Rhynchospermum jasminoides, Tacsonia Van Volxemi, and Tropæolum Ball of Fire. It will be best not to aim at too much. A few plants well grown will give more pleasure than a crowded collection spoiling each other. Tea Roses may either be planted out or be introduced in pots. I suppose there will be a small border round the sides of the house in which to plant the climbers, and this narrow border and the edge of the centre border could be always kept gay with plants in pots, or else be planted with Club Mosses and Ferns to give a green margin to the flowering plants. Undoubtedly having permanent plants in the borders will be the most economical arrangement, and if the selection is carefully made there may be flowers all the year round.—E. H.

3107.—**Plants for Small Garden.**—The first thing to do in the case of a piece of ground which has been laying in a neglected condition is to thoroughly work the soil, and bring it into a free mellow state before attempting to plant in it. This precaution is all the more necessary in the case of heavy retentive soils, which require considerable preparation to bring them into the desired condition. In the first place, we would throw up the soil into rough high ridges, that is to say, bring two spits together, thus leaving a furrow between each ridge of earth. Allow it to remain in this state all through the winter, when the united action of frost and wind will sweeten and pulverise it, so that by the middle of March it should be in prime order for the reception of seeds and plants. If at the same time some river sand such as builders use, road-scrapings, or ashes of any description can be added to it, it will be thereby rendered much more free and manageable. Choose a dry time in March, pull down the ridges and level the soil, breaking all lumps. Seeds of hardy annuals, such as Godetia, Clarkia, Bartonia, Collinsia, Mignonette, Saponaria, Leptosiphon, &c., may then be sown, to be followed a month later by Scarlet Linum, Mimulus, and Convolvulus minor, finishing up in May with Tropæolum, dwarf and climbing Canary Creeper, and climbing Convolvulus. Pansies and bedding Violas may be sown in June, transplanting them later on to their permanent quarters; Honesty, Canterbury Bells, and Sweet Williams to be sown in March, planting out when large enough to handle. In the sunniest position in the garden Wallflowers will succeed, and a portion of the wall where the sun comes should be devoted to Chrysanthemums, training to the wall and protecting when in bloom. Daisies and Pinks would in all probability succeed very well, as would also Columbines and such plants as Arabis albida, Alyssum saxatile, Aubrietia purpurea, the Gentianella, Christmas Rose, Winter Aconite, Snowdrops, Primroses, Polyanthus, Crocus, and Daffodils. A few Roses may be tried, and we would also plant Clematis Jackmani, lanuginosa, and candida, training them up to stakes or to the walls where not much shaded. Gloire de Dijon is a fine Rose for wall culture. Where but little sun comes Ivy must be planted, such as the small-leaved variegated, the large clouded, and the common Irish. Where much shaded, try hardy Ferns, London Pride, Daffodils, Forget-me-not, Primroses, Winter Aconite, Lily of the Valley, and Snowdrops.—J. C., *Byfleet*.

Roseate Maiden-hair Fern (Adiantum rubellum); suitable for cool greenhouse.

3095.—**Cactus not Flowering.**—Cereus flagelliformis, the cat's-tail or rod-shaped Cactus, is one of the most free-flowering species we possess. The pot containing it should be slung near the roof, so that it may get full light and sun, and where the pendulous habit may be displayed. Other free-blooming kinds consist of Cactus speciosissimus, Cereus Mallisoni, Colvilli, formosus, and rosaceus. Perhaps your plant is not yet large enough to flower; a Cactus requires several seasons' growth before it can produce bloom. In any case the effects of potting will not be seen until next year. It is on the wood of the previous season's growth that flower-buds are formed. Grow in the full sun during the summer, and expose them in the open air in a warm situation during the latter part of August.—J. C.

3097.—**Imperfect Fuchsia Blooms.**—Some error in the treatment has occasioned the formation of imperfect blooms. Fuchsias like a free, mellow compost of two-thirds turfy loam and one-third leaf-mould, adding thereto some silver sand. Next spring, when young shoots are beginning to form, allow the plants to dry out, turn them out of the pots, shake away all the old soil and replace in the same sized pot, shifting when required. Place in the open air in June until the buds are well formed.—J. C.

3094.—**Plants for Greenhouse.**—Tacsonia Von Volxemi would be a suitable plant for covering the wall, as it grows freely and flowers profusely. It will give the greatest satisfaction if planted out in a border of prepared soil consisting of loam and peat in equal proportions. About 18 in. of soil will do; the greater the width and length of the border the longer will the plant last in good condition. Cinerarias and summer-flowering plants generally merely require to be screened from frost, a temperature of from 40° to 50° being quite enough for them. The Cineraria likes a cool, moist atmosphere, but should never get in the least frozen, as it is one of those plants that never recover from the effects of frost-bite. Fuchsias from the latter end of October should be kept rather dry,

watering only when necessary, and giving just enough to moisten the soil through. In this manner the leaves will fall, but the wood will remain sound and plump. In March prune the young shoots back to three eyes, and when fresh leaves are formed shift the plants into larger pots. Balsams must be thrown away, as they are annuals, and the Coleus would do best in a warm room.—J. C. B.

3172.—**Culture of Ixias and Sparaxis.**—If required for pot culture the bulbs should be potted at once in fibrous loam, lightening the same by an admixture of leaf-mould and silver sand. Water gently, plunge the pots in a cold frame, giving no more water until the foliage appears. Keep the lights quite off, except in frosty or very wet weather, and early in February remove the plants to the greenhouse, where, if a gentle warmth is maintained, they will come into bloom by April. An easy method of growing them is to plant them out in a frame, where they will get just the protection they need; or a turf pit will do, covering in bad weather with shutters. When thus grown they will furnish a large amount of beautiful flowers for cutting in May. For open-air culture, plant in well-drained, rather light, and free soil in a warm situation in January.—J. C., *Byfleet*.

3171.—**Flowers for Fern Case.**—The attempt to grow flowering plants in a Fern case can only result in disappointment, the atmosphere being much too confined and damp for them. Better try and grow a few interesting subjects such as the Cephalotus follicularis, Cape Sundews, and Sarracenias, and such pretty variegated subjects as Fittonia argyroneura, Eranthemum sanguineum, and Sonerilla margaritacea. Some Orchids would grow in such a situation, but the flowers would spot as soon as opened.—C. B.

3196.—**Flowering Gladiolus.**—Want of vigour may be the cause of your plants not flowering satisfactorily; at the same time there are some kinds which do not open many flowers at a time, whilst others form a long spike and expand some ten or twelve blooms at once. These are the kinds most in favour for exhibition purposes. The Gladiolus requires to be highly fed, and from the time of expanding its first blooms must be screened from hot sun, or these soon fade. The following varieties are amongst the most satisfactory as regards forming a large spike of bloom: Le Vésuve, Horace Vernet, Eglantine, Mons. Legouvé, and Carnation.—B.

3169.—**Keeping Window Plants in Winter.**—We think that with a little management the plants in question may be preserved in good health through the winter, especially if a small stove could be fixed in the room, so that in severe frosty weather, a little fire being made, the inmates would be quite secure, and light could be constantly admitted, as there would then be no need to block up the window. Arrange the plants so that they get as much light as possible, and open the window when the weather is mild. Pick off all decayed leaves as they appear, and give the Geraniums but little water. The Calceolarias must be kept more moist, but with respect to this plant we will give you a useful hint, which we hope that others straightened for glass accommodation will make a note of. Take healthy young shoots, cut them in the usual manner of propagating, and insert them in a pot in light, sandy soil. Sink another pot a size larger in the open ground, keeping just the rim above ground so that water may not flow in. In this place the pot of cuttings, cover with a pane of glass, and cover up in severe frosts. Fine young healthy plants will be formed by spring. Fuchsias may be stored in any out-of-the-way corner until they commence to grow again, but should be pruned in in January.—J. C. B.

3216.—**Hardy Autumn Flowers.**—The finest of all autumn-flowering plants is the Japanese Anemone, the red and white varieties of which bloom freely until severe frosts come. A few clumps of this alone would make a border gay in autumn. When well established it attains a height of nearly 3 ft., but it requires well-stirred soil, a good coating of manure yearly, and copious waterings in dry weather. Rudbeckia Newmani is another showy plant, with large yellow flowers, growing some 3 ft. in height. Echinops strictus is a Thistle-like plant, with numerous blue flower-heads growing from 2 ft. to 3 ft. high, and Lobelia fulgens has scarlet flowers, and attains a height of 18 in. to 2 ft. Then there are the Michaelmas Daisies, the best of which are Aster Amellus, bessarabicus, longifolius, formosus, and sericeus, all running some 2 ft. high, and the Golden Rod (Solidago virgaurea). Another fine autumn-flowering plant is Clematis flammula, which should be allowed plenty of space to ramble, and which loads the air with sweet perfume during the autumn months. Plant in October and a good show of bloom will be obtained next autumn.—J. Cornhill.

3183.—**Spiræa japonica.**—Without the accommodation of a forcing house it is impossible to get the Spiræa into bloom by March. The best plan will be to plunge the pots in a cold frame until February, when they may be brought into a warm room, placing them in a light window, and giving air when conditions are favourable for so doing. A portion of the stock might be left in the frame to come along with the season. They will flower much finer and somewhat earlier when thus protected, as this plant generally gets injured by frost when in the open air.—J. C. B.

3202.—**Tea Roses.**—We willingly give you the best of our advice upon this subject, but we must admit that we do not expect that any great success will attend the attempt to grow Roses in the dwelling, they being plants that require so much light when growing. From this time forward until the middle of November expose the plants to the full air night and day; when they should be pruned back to three eyes, turned out of the pots when the soil is in a dry state, working away as much of the old earth as possible, replacing them in the same sized pots, using a compost of good rich soil. Then place them in an outhouse or cold apartment, keeping the soil just moist until February, when they may be introduced into a warm room having a sunny aspect. Give as much air as possible, and in April when the weather is very mild set them in the open for two or three hours daily. During the early stages of growth water very carefully, allowing the soil to dry out between each watering, and as soon as the foliage begins to develop, gently syringe or wash it about twice a week with tepid clean water.—C.

3182.—**Treatment for Eucharis amazonica.**—This plant requires a warm house where the temperature ranges from 50° to 60° in the winter. We would prefer to keep it in a warm room during the winter than to place it in a cool greenhouse, and we would not attempt to divide or repot at present, as it certainly flowers best when the pot is full of roots. During the summer it may be grown in an ordinary greenhouse, shading from hot sun, and feeding with a little weak manure water. Keep the foliage clean by frequent spongings during the winter, and sprinkle freely in hot weather.—J. C. B.

3213.—**Culture and Propagation of Bouvardias.**—Bouvardias are generally propagated by means of cuttings, furnished by plants which have been put into heat early in the year. The cuttings should be struck early in the spring, so that the plants get a long season of growth. Having filled a 4½-in. pot half full of drainage, cover the same with Moss and then fill to within 1 in. of the rim with light free soil, finishing off with clean silver sand, which should come quite level with the rim of the pot. Water gently and allow superfluous moisture to drain away. This done, take off the cuttings with a sharp knife, cutting each one to two joints and insert them immediately, placing the pot in a close case in a warm house where a minimum night temperature of 60° is maintained. Give a little air each morning, and when the cuttings are seen to have made root gradually inure them to the temperature of the house. In the course of a week each cutting should be potted off into a small pot in a well-sanded compost of two-thirds leaf-mould to one-third loam. Place them in a light position, shade from bright sunshine, promoting atmospherical humidity by syringing in hot weather. As soon as three joints are made nip out the point of the shoot, and when side breaks are formed shift into the next sized pot. By shifting on when needed, and pinching in the main shoots, a neat compact little plant full of wood will be formed by the latter end of May. Two courses are then open to the grower: he may either plant out in rich soil in a frame or shift on into 4½-in. pots. The former plan is more generally adopted, as being calculated to ensure a more luxuriant development. During the summer water freely, shade a little in hot weather, exposing the plants to the full air when the nights are calm and warm. Do not stop after the first week in June, and pot them up the beginning of October. By the latter end of the month place them in a warm house near the glass, and near the top ventilators, so that they get a free circulation of air. Plants thus treated will flower well and profusely throughout the winter months.—J. C.

3166.—**Lycopodium Moss.**—The Lycopodium delights in a cool, moist, shady situation, thriving perfectly well in a greenhouse or in a cool apartment. It is propagated by pulling the plant to pieces, taking with each piece a portion of the hard stem, and dibbling them in some sandy peat and leaf-mould. Keep the soil moist, but not too wet, or they will damp. March is the best time to divide it.—C.

3208.—**Winter Decorations.**—You cannot have a better plant than Grevillea robusta, which has elegant Fern-like drooping foliage. Aspidistra lurida is also an excellent subject for the purpose. The yellow Feverfew may be thus employed; it remains fresh and bright throughout the winter.—C. B.

3206.—**Plants for Baskets.**—We cannot help you to a list of flowering plants for baskets having the desired habit. Better fill them with nice foliaged plants, such as the Wandering Jew Saxifrage, Panicum variegatum (very prettily variegated), and Tradescantia zebrina. These three would form a charming contrast, and would remain in good condition throughout the year.—J. C. B.

3173.—**Climbing Rose Trees not Flowering.**—Want of vigour is probably the cause of the tree dropping its foliage. Cut out all the small shoots and prune back the strongest to about four eyes in March. During the summer give occasional waterings with liquid manure.—J. C.

3178.—**Cloches or Bell-glasses.**—These may be obtained of James Carter and Co., 237, High Holborn.

3175.—**Renovation of Soil.**—"Alpha" may dig in the ashes, soot, lime, and leaves, which will improve and lighten a heavy soil, but we should not recommend salt in such a case.—J. Carter.

2802.—**Botanical Distinction of Fuchsias.**—We do not think that botanical descriptions would enable you to determine the species in question. Can you not submit them to a good plantsman or gardener in the neighbourhood? In attempting to determine them by written descriptions you would still remain in uncertainty.—C. B.

3195.—**Climbing Plants.**—Cotoneaster microphylla Clematis flammula (not evergreens, but highly recommendable), golden variegated Honeysuckle, Clematis Jackmani and nivea and large clouded white and Irish Ivies. By planting the evergreens and Clematis alternately a charming effect will be obtained.—B.

3167.—**Winter Salads.**—Lettuces, Endive, Radishes, and Mustard and Cress can easily be grown in such a house; and Tomatoes, Cauliflowers, early Potatoes, Seakale, Asparagus, Horn Carrots, early Peas, and in short nearly all kinds of vegetables can be grown if there is space enough. Light, warmth, moisture, and air are the chief essentials, and if these are present in proper quantities success will be easy.—E. H.

3176.—**Plants for Conservatory.**—Camellias, Azaleas, Geraniums, Fuchsias, Genistas, Cinerarias, Primulas, &c. Creepers include Heliotropes, Habrothamnus elegans, Fuchsias, &c. Palms and tree Ferns would look and do well planted in a warm moist temperature.—J. B.

3191 & 3203.—**Pruning Gloire de Dijon Rose.**—In answer to above queries, I cannot do better than refer the writers to two articles on Roses in Gardening, Nos. 54 and 55, where I think they will find the information they want.—Hartside.

3197.—**Insects in Fern Cases.**—It is impossible to advise without knowing what the insect is. Is it green fly? The cast in the soil is caused by small worms, which have bred in or were introduced in the mould.—C.

3198.—**Gloire de Dijon Rose Withering.**—If the tree in question is healthy, we can only account for the Rose not expanding in the supposition that the weather has been too damp and cold lately in your locality. The last autumn blooms often fail to open well.

3109.—**Keeping Potatoes.**—To store Potatoes for any length of time they should be kept in a dark, dry, cool, airy place, and protected from frost.—J. Carter.

3098.—**Prickly Comfrey** (Symphytum asperrimum).—Unless "C. W." has a nice piece of rich free soil, and can dress with liquid manure, we should recommend Prickly Comfrey in preference to Lucerne, as being easier of cultivation. Stock of all kinds may be taught to eat it, and, when they know it, like it exceedingly. If any difficulty is experienced in getting them to taste it, bruise a little and mix it with the other food to begin with.—J. Carter.

3177.—**Kitchen Apples.**—Dumelow's Seedling, Kentish Fillbasket, Cellini, Manks Codlin, Lord Suffield, Warner's King.—E. H.

3210.—**Moving Apple Trees.**—The Apple trees may be moved, if the work be carefully done, as soon as the leaves begin to fall. Have them securely staked to prevent the wind swaying the tops about and displacing their roots.—E. H.

3125.—**Trees fer Shelter.**—For shelter plant the Huntingdon Elm or the Ontario Poplar, or if an evergreen is required plant Pinus austriaca. The Apples, if properly selected, will be ornamental inside the shelter; so would Pears.—E. H.

3212.—**Cucumber Disease.**—Stamp it out by destroying all the plants and everything in connection with them. Have the houses or pits well cleansed, painted, and whitewashed, and start again with fresh soil and seeds from a healthy stock.—E. H.

3119.—**Unfruitful Grape Vine.**—The north is a bad aspect for a Grape Vine. Better remove it, and substitute a Victoria Plum or a Morello Cherry.

3102.—**Autumn Planted Potatoes.**—If the land is retentive or not well drained, adopt the lazy-bed system, *i.e.*, throw the land into ridges with deep alleys between. Dig and manure the same as for spring planting, but plant deeper, not less than 6 in. deep. Plant in October.—E. H.

3101.—**Diseased Peach Trees.**—It is impossible to give any opinion about the diseased Peaches without knowing something of the symptoms, and of these Mr. Bolton does not say one word.

3110.—**Colouring Grapes.**—Bloom on Grapes is a very fragile thing, easily removed, but cannot be replaced. A dense bloom is a point of high culture, and where present signifies the interior management of the house has been suitable. Bloom is often removed by a late use of the syringe; by a careless application of moisture or ventilation its formation is prevented.—E. H.

3115.—**Planting Currants and Gooseberries.**—Trench the ground up 2 ft. deep, or deeper if the soil will bear it, working in plenty of manure; plant as soon as the leaves fall. Old Currant trees will not readily assume the espalier form—better start with young trees. The following are good sorts of Gooseberries: Red Warrington, Companion, London, Crown Bob, Champagne Red and Yellow, Criterion, Golden Sovereign, Victory, Rough Green, White Eagle, Whitesmith.—E. H.

3271.—**White Lisbon Onions.**—Better sell at a sacrifice now and plant the ground with Cabbages at once than hold them on till the spring. I should tie them in bunches and send them to market; they will do for present use, and will go at a cheap rate. The seedsman ought to bear a part of the loss for not supplying true seeds.—E. H.

3175.—**Renovation of Soil.**—The soot, lime, ashes, and salt will be beneficial dug into the land as suggested, but the Pear tree leaves will be better laid up in a heap till they decay, or be mixed with stable manure. If dug into the land at all bury them deeply, but they decompose quicker when exposed to the atmosphere.—E. H.

Although the following questions are answered by the Editor, he will be obliged to any of our readers who may think well to answer them according to their experience.

3284.—**Leaf-mould.**—*A. Calvert.*—Elm leaves make good leaf-mould, but Oak leaves make the best.

3285.—**White Worms in Garden.**—What can I do to get rid of a lot of small white worms that infest a part of my garden which had some fowls' manure applied to it?—ALFRED CALVERT. [Give it a good dressing of salt, lime, and soot.]

3286.—**Wistarias.**—Is Wistaria sinensis (common single lilac variety) perfectly hardy, *i.e.*, will it grow and flourish in a north or east aspect? also is it usually a quick grower? or does it take time to cover a comparatively small space? climate, S. Wales.—LA ROSIERE. [It is perfectly hardy, and will grow very rapidly in any position when once established, but it will not flower so well in a north or east aspect as in a southern one.]

3287.—**Veitch's Virginian Creeper.**—Is Ampelopsis Veitchi perfectly hardy? Will it flourish and spread in any situation out-of-doors, or must it have a warm aspect? climate mild and southern (South Wales).—LA ROSIERE. [It is perfectly hardy, and if planted against a wall in deep, rich, sandy soil it will grow very rapidly.]

3288.—**Nurseries near London.**—Will you kindly tell me the best and cheapest nursery south-west of London for procuring young trees and flowering shrubs?—ARUM. [There is little difference in the charges made for trees and shrubs by respectable nurserymen near London; you will be honestly dealt with at any of the well-known nurseries.]

3289.—**Shrubs in Lily Beds.**—I have just made a bed for growing large Lilies of hardy kinds; it is shaded by trees, but faces south-east. What plants or low shrubs can I grow to afford the roots shelter and make the bed look green? Can I plant Lilies of the Valley as a border in the front? I have been told they must have a bed to themselves.—E. C. [Choice Rhododendrons or evergreen Azaleas; any beautiful evergreen bush which you like and which does not grow too rampantly. Tufts of Lily of the Valley would do well towards the margin. The shrubs should be placed so far apart that there could be no possibility of their crowding even when old. In this way the character and beauty of habit of each will be better shown than in the usual one, while there will space for the finer hardy flowers between.]

3290.—**Gentians not Flowering.**—I have a few plants of the Alpine Gentian very healthy, but they never flower; they have been in the ground in fair garden soil two years. What can I do for them?—E. C. [If you mean the common Gentianella (G. acaulis), we do not see why it should not flower if it is not shaded too much. It might do good to make the soil firmer round the roots.]

3291.—**Champion Potatoes.**—*Monaghan.*—All these large coarse kinds of Potatoes are liable to be hollow. The reason some of the stalks remain green after the majority have died down is probably owing to the eyes being more dormant when planted; consequently they did not start so soon into growth as the others.]

3292.—**Fowls' Manure.**—*J. T. Z.*—This, mixed with soot and a good bulk of soil or road scrapings, will make excellent material for vegetable land of any description.

3293.—**Red Spider on Cucumbers.**—*J. C.*—Keep up a temperature of 70° at night and 75° to 80° by day; syringe the leaves well every morning early, and when you shut up the house at two o'clock in the afternoon, well saturate the floors, beds, and plants with water. When a sunny day occurs you might keep the house shut up close and syringe frequently during the day, but do not let any portion of the house get dry. Liquid cow manure in a diluted state is excellent for Cucumbers.

3294.—**Wintering Myrtles.**—I have some very large Myrtles in pots which are in the garden in the summer and in an out-house during the winter. Can any one tell me the best method of keeping the frost from them, and if they require to be watered often? One of my best died last winter.—E. B. B. [If the pots were completely buried 3 in. or 4 in. in a bed of ashes close to a wall, and the plants were covered over with a few mats or canvas during severe weather they would be safer than in a dark, draughty outhouse.

3295.—**Wintering Gladioli.**—Would it be safe to leave Gladioli in the open ground during the winter?—E. L. B. [Yes; if the soil is well drained and the roots be covered with ashes a few inches deep.]

3296.—**Raspberry Canes.**—My Raspberries have made numerous long side shoots? Should these be shortened or cut clean away?—E. L. B. [Cut down to the ground all canes which have borne fruit, and leave only those canes which were produced during the summer.]

3297.—**Musk and Lobelias.**—How can I keep some Lobelia and Musk plants through the winter? I have some in pots in the house windows.—BESSIE. [Keep them in a light sunny position in the window, and give them enough water to keep the soil from getting dry. Cut half of them down now, and the others in spring, and see which do best.]

3298.—**Wintering Lobelias.**—How can I keep Lobelias now in the flower beds until next summer?—BESSIE. [Cut off the flowers and seeds and pot the plants, and keep them in a window or greenhouse, giving them enough water to keep the soil in a moist, but not wet state.]

3299.—**Planting Bulbs.**—Should the bulbs of Tulips, Narcissi, Hyacinths, &c., be planted under the mould in the pots or above? I have planted them other years below, but they did never thrive, either in bloom or foliage, and the bulb nearly always rotted. If I commence with a fresh stock of bulbs, what bulbs would you advise me to buy? and how many shall I sow in a pot?—G. H. M. [The bulbs of Hyacinths and Tulips should be potted so that their crowns are just visible above the soil. After potting give them a good watering, and let them remain in the open air for a few hours to drain. Then bury them in ashes or Cocoa-nut fibre, 4 in. or 5 in. deep, until the pots get full of roots; then introduce them to a greenhouse or frame—one Hyacinth in a 5-in. pot, or three in an 8-in.; three Tulips in a 5-in., and five in a 6-in.]

3300.—**Draining Land.**—Last March you advised me to trench my ground 2 ft. or 3 ft. deep, and bury a quantity of old bricks, &c., to drain it. Can I do this now? or shall I wait until later on?—G. H. M. [Do it now.]

3301.—**Wireworms in Land.**—My ground is very much infested this year with wireworms and earwigs. Will you give me some information as to the destroying of same?—G. H. M. [Apply a good dressing of lime and salt, and let the land lay rough all winter.]

3302.—**Cropping Garden.**—My ground is now nearly empty, with the exception of a small plot of Turnips. What profitable vegetables, that can stand the hardship of frost, &c., could I sow seed of now?—G. H. M. [Get some Cabbage plants and plant thickly, and they will give you a few Greens by-and-bye. Dig up remainder of ground, and let it remain till January.]

3303.—**Begonias Eaten by Insects.**—Would some one give me a remedy for this? I have tried washing the leaves in Tobacco water, which has proved unsuccessful.—M. F. J. [It is probably a caterpillar or slug. Search morning and evening under the leaves.]

3304.—**Transplanting Raspberries.**—Will it do to transplant Raspberries just now? Also when should I cut down the old canes?—WILLIAM HERD. [Cut down the old canes now, and transplant the others in a month's time, or early in spring.]

3305.—**Propagating Pansies.**—If I sow Pansy seed now, will it stand the winter outside and produce plants to flower in spring? also will it do to strike cuttings now?—WILLIAM HERD. [The seed should have been sown in August. If you sow now it must be in a frame, where the plants can remain till spring, and be then planted out. Cuttings struck now will flower in spring.]

3306.—**Vines in Pots.**—Will some reader kindly inform me the proper time to plant Vines in pots? what sized pots? and in what soil?—E. J. D. [In what state are your Vines now? We cannot advise you without further particulars. Now is the time to purchase Vines in pots ready for fruiting next year.]

3307.—**Treatment of Adiantum farleyense.**—How should I treat this Fern?—F. W. [Keep it in a temperature of 60° shaded from the sun. Give plenty of water at the roots, but do not wet the foliage.]

3308.—**Length of Pipe for Vinery.**—What length of 4-in. pipe will be required to heat a span-roofed greenhouse 18 ft. long, 12 ft. wide, and 12 ft. high at the ridge, inside measurement, in order to be able to force the Black Hamburgh Grape?—CHINGFORD. [Two rows all round, or if three be put all the better.]

3309.—**Planting a Garden with Fruit Trees.**—My garden is 100 ft. by about 124 ft., and enclosed by a wall 7 ft. high. The soil is mixed, rather gravelly, subsoil loamy, well drained. I want to plant the walls with Plums, Apricots, Peaches, Cherries, and Pears. What are the best sorts to plant, and the distance apart? and which aspect would suit the different kinds?—A NEW BEGINNER. [If you adopt the fan system of training, which might perhaps be the best in your case, you will require fewer trees, and if you select those three years trained you would not be long without fruit. One south wall should be planted chiefly with Peaches and Nectarines, and the other with Apricots. The west wall should be planted with Pears, and one east wall with Cherries, and the other with Plums; the north walls with Morello Cherries, Plums, Gooseberries, and Red and White Currants. Plant the Peaches, Nectarines, Apricots, Plums, and Cherries 18 ft. apart, and the Pears 20 ft. The walls are so low, the trees will require space to extend laterally. The following are good sorts to plant: Peaches—Early York, Royal George, Alexandra Noblesse, Lord Palmerston, Walburton's Admirable; Nectarines—Downton, Elruge, Victoria; Apricots—Moor Park (chiefly), Hemskirke Peach; Plums—Green Gage, Transparent Gage, Golden Drop, Washington, Kirke's, Blue Imperatrice, Victoria, Pond's Seedling, Magnum Bonum, Goliath; Cherries—May Duke, Black Tartarian, Governor Wood, Holman's Duke, Elton Bigarreau (Frogmore), Morello; Pears—Beurre Bosc, B. Brown, B. d'Anjou, B. Easter, Jargonelle, Williams' Bon Chrétien, Pitmaston, Duchesse d'Angoulême, Dovenne du Comice, Foudante d'Automne, Marie Louise, Glou Morceau, Winter Nelis, Bergamot d'Esperen. Plant as soon as the leaves fall.

3310.—**Tomatoes for Winter.**—*Novice.*—Place the plants on a shelf close to the glass in a house where a temperature of at least 60° is kept up. When in flower pinch out the growing points of the shoots on which the flowers are produced.

Old Indian.—Kindly send us your address and we will communicate with you.

Heating Greenhouse.—*O. G. K. Y.*—See GARDENING Sept. 4, page 321.

May Flowers.—*W. H.*—Send us a branch, and we may be able to tell you the name.

Names of Plants.—*Credo.*—Double Marigold (Calendula officinalis).——*J. R.*—Japanese Honeysuckle (Lonicera japonica variegata); it will grow up a wire fence 6 ft. high; it does not bloom.——*Tom W.*—Tradescantia zebrina.——*E. A. H.*—Bocconia cordata.——*T. R. M.*—Some of the large Rose growers might possibly help you with similar material to that you send us, but we cannot.——*Constant Reader.*—Musk; send us something more than a dried-up leaf.——*E. S.*—Send us a spray of the small Fuchsia, and we may be able to name it; there are lots of kinds with small flowers.——*Bebington.*—Spar-mannia africana; it will do in a greenhouse.

QUERIES.

3311.—**Soil for Gum Flax.**—Can any reader inform me the treatment and soil required for Australian Gum Flax and Silver Leaf? I believe they are natives of Australia. I had some seed given me which I sowed, and the plants have come up.—A SUBSCRIBER.

3312.—**Pines in their Native Habitat.**—Can any reader tell me from experience how Pines grow in their native country?—J. BURFORD.

3313.—**Plants for Greenhouse.**—I have just completed a small greenhouse, 12 ft. by 6 ft. Will any of your readers kindly inform me the most suitable plants to grow?—CITY OF LIVERPOOL.

3314.—**Wireworms in Lily Bulbs.**—I have grown Lilium auratum for many years, and every year I have lost a quantity of bulbs, and in every case of death I have found wireworms in the pots. I am very careful with the potting mould (good loam, sometimes a mixture of peat). I look over it and break up any lumps to prevent these pests passing me. I wish some one could suggest any other means of getting rid of them. I am not troubled with them in any other Lily in this manner. My bulbs are all imported ones. Is it possible that they come over in the bulbs, because in one instance I found a worm before potting?—C. E.

3315.—**Climbers for Covering Porch.**—I wish to cover a porch facing north with handsome creepers, that at the same time grow quickly (not Ivy or Escallonia). What should I plant? Will Ayrshire Roses do? and would they bloom, or would no kind of Rose succeed in such an aspect (climate mild, South Wales)?—LA ROSIERE.

3316.—**Lilium auratum.**—I should be glad to have such instructions as to the successful growth of this bulb in pots as may lead to a better return of flowers than has been mine this year, as I have only one bloom on a bulb of the largest size?—S. N.

3317.—**Making Lawns.**—Will some one kindly give a full description of how to prepare the ground for and lay down (with seed) an entirely new lawn? the ground would have to lie fallow until the spring.—ARUM.

3318.—**Furze Hedges.**—Would Furze be a good material to face the south side of a Thorn hedge? and if so, what would be the best time to plant it? The soil is sandy loam, well drained. Is there any variety of the common Furze more vigorous in growth than others? I lately saw at Bournemouth tall hedges of this plant, beautifully green, and close from top to bottom, and I should be glad to have one like them here if possible.—J. M.

3319.—**Fruit Trees.**—Will some one name the fruit trees most suitable for training against Oak palings facing W. S. and E., suburban garden with stiff clay subsoil? When should trees be planted? and what precautions should be taken?—S. W., *Aylesbury.*

3320.—**Roses for Clayey Soil.**—Please name best sorts of hardy standard or dwarf Roses for W. S. and E. aspects, stiff clayey subsoil.—S. W., *Aylesbury.*

3321.—**Lily of the Valley among Grass.**—Will Lily of the Valley thrive among Grass? The Grass has seated itself too deeply in my bed for hand-picking, and I fear the use of the fork would injure the Lily roots.—M. J.

3322.—**Pyrus japonica.**—Will any one kindly give me some information as to the culture of Pyrus japonica? Mine, which is trained against a south wall, grows so slowly, though it generally blooms well. I should like to know how it should be pruned?—E. A. H.

3323.—**Hyacinths for Windows.**—Will some reader favour me with directions as to soil and manure for Hyacinths, time of planting, &c.—J. E. CHEESE.

3324.—**Old-fashioned Flowers.**—I have a border 100 ft. long by 2 ft. wide, facing the S.W. Can any one give me a list of cheap old-fashioned perennials suitable for such a border? At present it is fallow, but has had Strawberries on for a year or two.—ORNITHOLOGIST.

3325.—**Name of Rose.**—Can any one tell me the name of a Rose that grows on the wall of the Villa Doria, at Genoa? It is a large yellow Rose, with a peculiar blood red shade through it.—H. J. P.

3326.—**Cinerarias Dying off.**—I have raised some Cinerarias from seed sown in April, but they do not grow ½ in. from the soil; they make plenty of leaves, but they die off. What am I to do, as this is not the first year that I have had the same difficulty with them?—TOM W.

3327.—**Roses for Arches.**—Will some one give me the names of the four best climbing Roses for training over single arches about 8 ft. high? Would Gloire de Dijon be suitable?—H. S.

3328.—**Flowers for Verandah.**—What plants (flowering if possible) would grow on a north aspect trained up the supports of a verandah where there is very little sun?—H. S.

3329.—**Lavender Culture.**—Having been informed that growing Lavender is very profitable, can any one give me information as follows? If it could be grown successfully in Norfolk: what rate of profit per acre would it yield; mode of cultivation; and first cost of plants or cuttings; whether any special class of ground is necessary.—ENFIELD.

3330.—**Sea Sand for Plants.**—Will some reader kindly tell me if sea sand is of use in making up soil for

flowers in the same manner as silver sand is? If so what kind of plants is it best suited to?—Inexpertus.

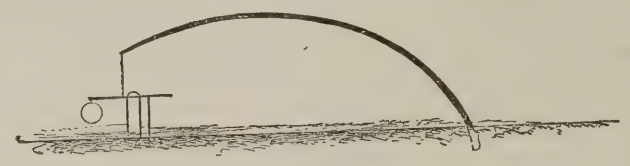
3331.—**Trees for Clay Soil in Devon.**—What kind of ornamental trees, which grow quickly, could I plant near a house in South Devon situated high, and therefore exposed to rough winds? The soil is heavy red clay. I do not want common Firs, &c.—Sevarg.

3332.—**Red Potatoes for Exhibition.**—Would some reader inform me which are the best red round Potatoes for exhibition?—W. G. S.

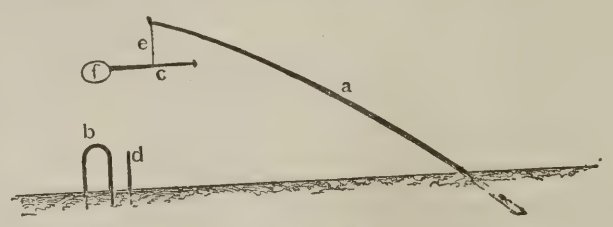
3333.—**Propagating Pyracanthas.**—Will any reader of Gardening Illustrated tell me how to strike cuttings of this? also the proper time for pruning? and what month should trees be removed?—M. B. G.

POULTRY.

Rats in Fowl Houses.—I have always found the following a very good plan to get rid of rats: Cut a good strong stick *(a)* about 3 ft. 6 in. or 4 ft. long, and another small one *(b)* about 1 ft. long. Tie a double piece of twine *(e)* about 4 in. long to the top of the longer stick. Next procure a small piece of stick *(c)* about 4 in. long, make it round at one end and flat at the other, cut a groove round the middle of it to keep the string from slipping, and tie it to the other end of the piece of twine. Now take a piece of thin copper wire, make a running noose *(f)* at one end of it, and fasten the other end securely round the small piece of stick in the same groove as the twine. Cut yet another small piece of stick *(d)* about 8 in. long and your trap is complete. To set it, bend the stick *(b)* into the form of an arch, and stick it firmly into the ground by the side of the rat's run. Next take the small stick *(d)* and stick it in the ground about 3 in. behind the arch, that is, away from the run; now stick the long stick into the ground, and bend it down towards the others: take the stick *(c)* and place it under the arch *(b)*, and rest the end on the top of the stick *(d)*, so that the noose is about 1 in. from the ground. As soon as the rat finds his head in the noose he struggles to get free, which displaces the stick *(c)* from the top of the stick *(d)*; the stick *(a)* then springs up and swings the rat up into the air and strangles him. I think this is one of the most useful traps one can have, as it is impossible for fowls to get hurt in it.—W. T. D.



Trap set.



Trap unset.

Diarrhœa in Poultry.—This disease in poultry is often caused by a sudden change of food, but more often by poor food, combined with exposure to wet and cold. If seen to in its earlier stages it is readily checked, but if allowed to run on it often causes death at the expense of severe suffering. The affected bird should be confined in a warm dry pen, free from draught and fed on soft food only, drink of any kind being withheld. Oatmeal made rather wet with boiling milk and with a good sprinkling of chalk and either cayenne or pulverised cinnamon will in most cases effect a cure. Two teaspoonfuls of cold brandy and water may be given twice a day. Some advise a dose of castor oil before treating as above. In severe cases small quanties of laudanum may be given, dose half-a-teaspoonful twice a day. A fruitful source of diarrhœa is in giving the birds sudden access to unlimited green food after they have been deprived of it for some time.—Andalusian.

Fowls with Coughs.—I have seen with interest the inquiry of "F. H. A." as to fowls with coughs. In attempting to cure a disease it is essential to determine its cause. The causes of coughs in poultry differ. It is possible in the present instance that a peculiar species of worm in the windpipe or lungs may cause the cough, which is not improbably analagous to the "hask" or "husk" in calves, which has, I believe, been prevalent this year, at least in this district. If this be the case, softening the food given will have little practical effect. There are in a fowl two tubes—one through which the air passes to the lungs, the other through which the food reaches the crop. Food or medicine given in food would, I suspect, only affect the lungs indirectly by permeating the system through the blood. To reach the worms (if these be the cause) the birds must be made to inhale some vapour strong enough to kill the worms, but not the fowls. Powdered sulphur burned in a large flower-pot saucer on hot coals would possibly do this, or the vapour of a small quantity of carbolic acid would probably be still more effective. Of course, the birds must be carefully watched during the operation. They might be placed in an open-worked basket in a small outhouse or large box, where the vapour could be confined. The operator must necessarily be guided by their appearance, and himself take care not to inhale (especially the carbolic acid) fumes.—A. K. C. L.

Hens not Laying.—I feed my hens on Maize and give them milk to drink, but they do not lay, and, as they are not moulting, I am at a loss to account for it. What is the best plan to adopt with them?—B. J. C.

Salt for Poultry.—Salt is bad for hens, as it causes blindness.—W. B.

Rearing of Poultry.—*S. R. T.*—The Honourable Mrs. Arbuthnot's book on poultry is a good one. It is called "The Henwife."—Mrs. M.

Duck with Webless Feet.—I have a drake with no webs to his feet and his bill pointed, the edges turned up and serrated. Is not this a curiosity? He was one of eight of my own settings; six were as usual, and there was one drake like this one.—G. W.

Broody Hens.—Forty years' experience teaches me that the happier fowls are the more eggs they lay, consequently I disturb mine as little as possible. Putting fresh ones in disturbs their laying for a week. When a hen has laid a lawter, Nature requires rest to keep her healthy. My practice is to let her sit on a dummy egg in the breeding compartment away from the others; she has a dust bin to roll in. I feed her once a day. At the end of three weeks I take away the nest and turn the box upside down, keep her there for two days, then turn her in with the others; she takes no more notice, and in a week commences to lay. I believe I get as many eggs as is possible to get by any undue pressure.—T. C.

Fowls' Feathers Coming off.—One of my Dorking hens has now been for about two months stripped of its feathers from its back and head. I have waited to see if they would grow again, but it seems as if they will not. I feed the fowls twice a day on poultry mixture and once with scraps from the kitchen table. The mixture contains Hemp seeds, which I have been told is the cause of feathers falling off. How can I get the feathers to grow again?—G. H. M.

Books on Poultry.—Lewis Wright's "Illustrated Book on Poultry" is now considered the standard work on poultry; Tegetmeier's is also very good. There is a cheap work, published at 170, Strand, entitled "Poultry for Prizes and Profit," and another on "Fowls," by Baily, Mount Street, London, both useful little works.—J. D.

Vermin in Fowl Houses.—I have found washing the nests and floors of fowls' houses with diluted carbolic acid is a good way to destroy vermin. See also that the fowls have plenty of ashes to roll in.

HOME PETS.

Parrot Poisoned with Parsley.—Can any reader tell me if Parsley is poison to parrots? We were told it was so, but a servant not knowing it gave a piece of Parsley to a parrot last week; all that day the bird would not eat or speak, and next morning was lying dead in its cage. As Polly was in good health and plumage up to the time of eating the Parsley, and there was no apparent cause for her death, I should like to know if any similar case has been known; also what poisoning properties Parsley can contain. The parrot was dull and drowsy, but her feathers remained unruffled.—H. J. P.

Baths for Cage Birds.—Will some bird fancier kindly explain whether canaries or any other cage birds should receive their bath whilst they are moulting.—Amateur.

Canaries for Exhibition.—Will some one kindly say which are the best sort of canaries for show purposes?—Amateur.

Keeping Jays.—"J. V. M." should feed his jays on Acorns, fruits, Beechmast, worms, cockchafers, and other insects, as well as mice, frogs, and small reptiles, or they may be fed like the raven upon pieces of raw meat (beef and mutton being preferred), ground Oats, mixed stiffly, and any table scraps; they are also fond of picking a bone.—Canary.

Breeding Canaries.—Having a convenient place, I wish to go in for breeding canaries; will some of your readers inform me as to the best time to commence, and the best book of instructions to procure.—Beginner.

Book on Goats.—"Kid" will find the address of the British Goat Society at 6, Strand, and the best and only book, I believe, at a shilling, is the "Book of the Goat," published at 170, Strand, W.C.—G. Robjent.

BEES.

Commencing Bee Keeping.—I have read the article by "Bar Frame" in Gardening Illustrated of September 11 with the greatest pleasure. I wish he would give us more of his experience. I began to keep bees a short time ago, and bought a stock hive from near Hitchin. I met it at Finsbury Park Station, where I found the bees had got out and were flying about, when I got it home, and found that the honeycomb had got knocked down and probably half or more of the bees were killed. The bees again got away whilst I turned the hive upside down, and got four pieces of comb in again. The bees had settled then on a wall. I brushed them into a new skep which I inverted under the old skep with the comb in (fastened by two canes). After being out for the night the new skep was taken away and the floor board put under the old one. The bees are in now, and appear only to cover the inside of the two middle combs, that is so far as I can make out by lifting the skep and looking under. Possibly the queen bee was destroyed with the others. I want advice as to how to proceed now. There is a bung in the crown of the skep, but nothing over it. Would it be well to try to get another lot of bees into the skep to strengthen the hive, and make sure of its having a queen? The honeycomb with honey, dead "brood," &c., not utilised is at my disposal—more than half of what was in the hive at first. Would it be well to get a "frame" hive fixed in some of this comb, then put in bees obtained from some one with a swarm at his disposal, and try to keep them through the winter by feeding? I may say the bees were out two nights near the hive.—J. W.

Bee Keeping.—"Kensington" may commence bee keeping at once by purchasing a stock or swarm, but they will not work in supers now. The months of May, June, and July is the proper time for supering. The price of a stock will depend on what kind of hive they are in; bar frame hives are most of them dear. A common straw flat-top hive, weighing with bees and honey about 30 lb., may be purchased for about 30s. to £2, according to the weight of the hive.—Apiary.

Disposing of Bees.—I wish to dispose of six or seven beehives or their contents. Living in rather an out-of-the-way part of Ireland, I find no sale for them. Will some one suggest what I ought to do?—C. D. E.

Bees in Windy Weather.—I have read that bees in windy weather take up little stones to poise themselves when flying, as described by Virgil in his "Georgics," Lib. iv., 194, 195, and also by Aristotle. Is it true?—D. E. M.

Slinger for Bees.—"Bar Frame" says any tinker can make a slinger. I would like very much to get one, but don't know what it is like, and can't get a tinker to work without instructions. Would "Bar Frame" give directions with dimensions, and if possible a sketch of what a slinger is like? I am sure it would be a great boon to many who, like myself, are beginning bee keeping.—A Novic

Dark Honeycomb.—"Amateur Bee Keeper" will always find comb dark that has been three or four years in the hive. As to its being empty, it is either from the death of the queen or from robbers. Bees will rob each other, and wasps are great robbers of honey at this time of the year. If you wish to drive your other hive you can do so of course, but lift it up first to see if it is worth driving. If it is a late swarm it may be empty, but you must feed the bees liberally if you drive them. Not less than 25 lb. of syrup should be given to each hive.—Apiary

Keeping Bees through the Winter.—I have lately bought two stocks of bees, and find the hives are full of combs, that one hive weighs 21 lb., and the other 22 lb. without the floor board. Is this sufficient to keep them well through the winter? and if not, how must I feed them, and what with? I wish them to throw off strong and early swarms, and shall be thankful for any hints to attain this end. I should add that the hives are made of straw and rather old.—A Weaver.

We regret to announce the death of Mr. Arthur Veitch, of the firm of Messrs. Veitch and Sons, Royal Exotic Nursery, Chelsea, which took place quite unexpectedly on Saturday, September 25.

REGISTERED FOR TRANSMISSION ABROAD.

WHITE LAPAGERIA (L. ALBA).
Sketched from a Spray of Flowers grown by Mr. Titus Salt.

LAPAGERIAS.

If we had a greenhouse, either heated or unheated, in which there were only room for one climber, we would plant the white Lapageria (L. alba). If two plants could be accommodated, we would add the rose Lapageria (L. rosea). Both will grow well and rapidly when they once get a start, and yield an abundance of wax-like blossoms all through the autumn months. A greenhouse kept at a temperature of 40° to 45° during winter suits the Lapagerias best, but in an unheated greenhouse they will grow and flower freely so long as their roots never get frozen. Lapagerias do fairly well in pots filled with moist, fibrous peat, with the addition of a little turfy loam, but they must not on any account be allowed to become dry at the root. Planting out, however, will be found to be the best plan, if there is convenience for so doing, as it is less troublesome to the cultivator, and gives better results. When planted out in a cool, peaty compost, and trained on the roof of a partially shaded greenhouse, Lapagerias seldom fail to make luxuriant growths and to flower abundantly. For glass corridors such plants are peculiarly adapted, and never fail to bloom well if liberally treated with regard to moisture when making their growth. The shoots should be trained close to the glass, where they will flower their whole length. The best plan is to stretch wires 4 in. or 5 in. apart in the direction in which the shoots are to be led, and they should be allowed to follow the wires themselves, which they will do—twisting along as neatly as possible—without the least assistance, except that when more than one shoot is allowed to a wire care must be taken to prevent the leaves being caught in the twists. To attempt training the shoots by ties is troublesome, and not a successful plan. Stopping the shoots occasionally induces flowers to come sooner than they otherwise would do, and produces little spurs, each of which furnishes several flowers. When the wires are covered the side shoots should be allowed to droop loosely, by which means, when thickly laden with bell-shaped, waxy flowers, a much better effect is produced. In sunless places in cool houses even in London these plants succeed perfectly, and can therefore scarcely be too highly valued. Lapagerias may be planted almost at any time from March to October with every prospect of success. If plants be obtained from a nursery in pots, they should be turned out, and the soil should be carefully loosened from the roots, which, when clear, should at once be laid carefully and regularly out in the new compost, covering them with 2 in. of fibrous peat rubbed through the hands. A good watering should then be given, and the soil never after be allowed to become dry. Lapagerias are generally propagated by means of layers, but the demand for the white variety, which is still sold at rather high prices, has induced raisers to try more expeditious plans of propagation. Layering is, however, the safest plan. The shoots of the previous season are simply bent down around the parent plant, and pegged on a bed of peat and sand, and covered over, leaving the point of the layer above the soil. Roots are formed at the joints, and several plants sometimes spring from the same shoot, springing up like Vine eyes but the points of the shoots usually make the strongest plants. When the Lapageria is propagated by seed—a plan not to be recommended—the seed should be sown as soon as ripe in a pan of fine soil, covered with a pane of glass, placed in a gentle heat, and kept moist.

VEGETABLES.

HOW TO GROW GOOD LEEKS.

Preparing the Soil.—The soil in which it is intended to grow Leeks should be lighter than that in which Onions are generally cultivated, and they thrive best in alluvial deposits of rich black earth thoroughly impregnated with decomposed manure. What is known as rank manure is not at all suitable. The best mode of preparation for Leeks is to dig or trench the ground early in autumn, covering it with a heavy coating of manure, and leaving it as rough as possible during winter to mellow the surface and assist in the perfect decomposition of the manure.

Sowing.—About the middle of February sow the seeds either in rows at distances of 1 ft., or even 2 ft. apart (according to the richness of the soil, the mode of culture to be adopted, or the size to which the produce is expected to grow), or in a seed-bed of rich soil. The seeds should be covered with about ½ in. of soil, and the surface finished in the same way as for Onions. Sow again in March, April, and even May, for successional crops; these latter sowings should be in drills from 12 in. to 15 in. apart, and the plants should remain where sown to come in during the winter and spring months. Where a constant supply of Leeks is required successional sowings are necessary, for the first-sown will grow under liberal treatment to a large size, and are not so hardy as those of a smaller size and later growth; all that is requisite to be done is to thin them to the extent of from 6 in. to 12 in. apart in the rows and to keep them clear from weeds throughout the summer; those sown in March might also be earthed up with about 4 in. of earth on either side of the stems before winter sets in. The success of the crop is mainly dependent upon the manner of sowing the seed, which operation should be performed thinly, whether in drills or broadcast on a seed-bed, in order that the plants may not be weakened, for thousands of plants are crippled and damaged for life by overcrowding in nursery beds and lines, which no subsequent attention can repair.

Thinning and Earthing.—On the heels of thin sowing severe and prompt thinnings must follow, which thinnings may be planted in either of the ways described further on. But I will first deal with rows planted so widely apart as to be left till the Leeks have attained their full size where sown. As soon as the crop is thinned to about 1 ft. from plant to plant, hoe the ground well to clear the surface of seed weeds; within a week, draw some loose sweet earth up, so as nearly to touch the Leeks on either side, and leave a small ridge 1 in. or 2 in. from the plants, which will then stand in a small drill. Hoe the level surface again, and as the Leeks grow, draw a fresh supply of fine, sweet soil to increase the size of the ridge, and so proceed throughout the season. As they develop in size of top and number of roots, sprinkle a little guano on the surface before each earthing up, and flood it occasionally with guano water or house or yard sewage, for the Leek is a moisture-loving plant with a superabundance of roots, and should never be allowed to become dry; if the plants receive such stimulating and nourishing treatment as that just mentioned, they will make extraordinary progress. After August the earth may be drawn up quite close to the stems on either side, forming a ridge from about 1 ft. to 1½ ft. in height, which will have the effect of blanching the stems to that height, and will insure that whiteness, solidity, and mildness which are the chief recommendations of a perfect Leek.

Growing in Trenches.—Another mode of growing fine Leeks is to form trenches for them in the same way as for Celery, though not so wide—9 in. or 12 in. being quite sufficient. Fill each trench at the bottom with about 6 in. of well-rotted, rich, light manure; surface this with a few inches of soil, and leave the top from 6 in. to 12 in. deep. Plant the Leeks out of the seed drills or beds into the trench in dull, showery weather, taking care to preserve all their roots. This will be found a most convenient method to allow of the easy application of water and manure. See that the plants are kept clear of weeds. As they advance in growth fill in the earth a little at a time; this will refresh and stimulate the plants. By the end of the season the trench will be level with the surface, or probably converted into a slight ridge on either side of the Leeks, which will be from 12 in. to 18 in. long, thoroughly blanched, and of the finest quality. Leeks are sometimes planted with a dibble in newly-dug, highly-manured ground in the same way as Cauliflowers or Cabbage plants, and simply left to shift for themselves.

Crowbar Planting.—This is the last mode to which there is any occasion to refer, and it is doubtless one of the best The ground can hardly be too rich and fine for this style of planting; where it is otherwise, a huge crowbar or dibble is often used to make a hole from 18 in. to 2 ft. deep, and about 4 in. in diameter; several inches of the hole are then filled up with rotten manure or rich compost, on which the Leek plants are then dropped, and frequently left to shift for themselves without any subsequent treatment; and they mostly grow so fast that before the autumn their long blanched stems have filled the holes and hidden them and the whole gronnd with crowns of enormous leaves. It used to be customary to crop the leaves of Leeks at the time of planting to check evaporation, and also, as was supposed, to throw more strength into the roots and stems, while some cultivators, with the same mistaken notion of the effect, took the points of the leaves several times during the summer; but experience has since proved that the leaves and the roots must be left intact as far as is possible if the finest Leeks are to be produced.

Lifting the Crop, &c.—These useful vegetables are in season from September to April, though it is possible to have them earlier and later. Those sown in February will last until the end of January, and those later sown will keep well without running to seed till April or May. Many cultivators take up their Leeks in the autumn, and "heel" them in closely together, and rather deeper than previously, after the manner of Broccoli; some also cut off the roots, and store them in earth or sand like Celery is preserved in cold climates; they are, however, apt to lose flavour when kept long after this fashion either in the ground or in a cool cellar. It is a common practice with those who wish to prolong the Leek season as far into the summer as possible to lift the entire crop about the middle of March, and lay in the plants pretty closely together, without unduly crowding them, in a north border, choosing the shadiest and coolest position.

Varieties. — There are several kinds of Leeks, as the St. David's, Musselburgh, London Flag, Ayton Castle Giant, Large Rouen, and others, all garden selections from the original species—Allium Porrum, and perhaps A. sativum and A. lineare, either of which will develop into fine Leeks if well cultivated. There are few plants that pay better for liberal treatment, or sooner resent neglect in any shape, than Leeks. D. T.

Scarlet Runners for London Gardens.—On my way through Hammersmith the other day I noticed that the outhouses belonging to several cottages were almost entirely hidden by the green foliage and flowers of the Scarlet Runner; and, contrasting these places with others that were black and grim-looking, I could not but regret that so few of the inhabitants of London turn to account their small but valuable space in this way. Nothing is more easily accomplished than to cover all available spaces with Scarlet Runners, which, in addition to forming a pleasing and refreshing sight to passers-by, would be a source of pleasure, as well as a pecuniary benefit, to the occupiers. A plentiful supply of water and a fairly-drained ordinary soil is all that is required to ensure success. Liquid manure is, of course, a great help in poor soils.—S.

Parsley for Winter.—I know of nothing in a small way so useful as Parsley. Many take it up and grow it under glass, but no coddling is needed. When we plant our Broccoli in July, we take a little Parsley seed and sow it broadcast amongst them. The young Parsley plants grow with the Broccoli, the large leaves of which duly protect them in the winter, so that a good supply is always at hand.—R. G.

Lifting, Wintering, and Cooking Beetroot.—Frost is most injurious to Beetroots, which should, therefore, be dug up by the end of October, or provision should be made for protecting them in the ground, in the event of severe weather setting in; this latter mode, though it entails the greatest amount of labour, is really the best way of preserving the full flavour of the root. Stable litter, hay-bands, or Bracken (Pteris aquilina) will effectually protect Beet, but, of course, where neatness is studied rather than utility, this manner of protection should not be thought of; in that case, the roots should be dug up at the time mentioned above, and "clamped" in the same way as Potatoes; or they may be layered in dry soil or sand in a cool shed, but it must be really cool, or they will start into growth and the flavour will become deteriorated. When lifted, the tops should not be cut but screwed off, and the roots should not be injured more than can be helped, as such injury induces decay. Before cooking, the roots should be well washed, but not peeled or scraped, or in any way bruised, for, if such be the case, much of the saccharine matter escapes during the boiling, a process to which preference is generally given, and this mode of cooking doubtless renders Beet most agreeable to the generality of palates; though some prefer to bake it, by which mode a deeper colour of flesh is ensured and a firmer texture, and where these are desired, or the roots much bruised, baking should be the plan adopted.—W. W.

A Cure for Clubbing in Cabbages.—During this season I have been greatly troubled with clubbing amongst the several varieties of the Cabbage family, for the removal of which I have tried sundry remedies. The following treatment I have found to be quite successful:—Having planted seven rows of Brussels Sprouts by way of experiment, I made a paste of equal parts of loam and manure, to which I added some red lead, mixing all well together; the roots of two rows of the plants were covered with the paste exposed to the sun for an hour and then planted; the plants in these two rows are quite as large again as the others, and are all of equal size, while the remaining five rows are clubbed, and they seem to diminish instead of increase in size.—W. S.

Destroying Wasps' Nests.—I have seen many remarks lately about the unusual number of wasps and the best mode of taking their nests. I have taken ten about my house with the greatest ease and safety by means of a common squib of gunpowder rather moist. Go after dark to the nest, light the squib, and put it into the hole; then put a sod on the top for two or three minutes; then dig out the grubs and comb and destroy them. Pouring in water or coal-tar, &c., will not do, as very often the nest is higher than the hole; and although the wasps are stupified for a time they revive afterwards, and the young ones hatch out. To destroy the nests properly the grubs and comb must be dug out, and the grubs make good bait for fishing.—D.

Salt as Manure.—When applied as a winter dressing to vacant land the beneficial results of salt are twofold—it destroys insects, and, when thoroughly incorporated with the soil, eventually assists growth. When applied to crops in a growing condition, the best plan is to administer it in a liquid state and largely diluted with water, for although some vegetables will withstand strong applications of it, it is at all times wisest to use it harmless as regards strength, and to give it more frequently. Most of the Cabbage tribe are improved by its application, also such root crops as Beet, Parsnips, &c.; Celery is likewise greatly invigorated by it when given in a liquid form, and its application is a means of keeping off the attacks of slugs and similar plagues, which in some soils greatly disfigure it.—J. G.

FRUIT.

SETTING OUT ORCHARDS.

In this operation two important requisites must be kept in view: the first is to do the work well, and the second is to do it at small expense. If needless cost is avoided, the owner can afford to perform the operation better than where every part is encumbered with heavy outlay. For example, if instead of doing all the digging by hand labour, a large part can be effected with horse power, there will be less occasion or excuse for its superficial performance. The more nearly straight the rows are set, the easier will it be to cultivate between the trees. The best way is to mark off intended rows with stakes driven into the ground on the four sides of the allotted piece of ground. Procure a strong cord, which may be as long as one side of the ground, or as long as a portion. With a measured pole mark off the distance for each tree, and stick a common pin through at that point as a temporary mark. Then, for permanent and more visible marks, sew red yarn through the cord; this may be easily seen in future operations. This cord will enable the operator to stake out easily and correctly the four sides of the lot. Be careful to have these outside rows of stakes straight. Next, to save the labour of digging large holes by hand, and to supply a deep mellow bed of soil for the future roots of the trees, run the plough straight across the field between opposite stakes for each row. Allow 6 ft. wide for each ploughed strip of ground, beginning outside of this strip and throwing the soil outwards from the centre. Repeat this ploughing, and then deepen the loosened bed of earth with a subsoil plough. Previous under-drainage is, of course, essential if the subsoil is liable to hold standing water; and the addition of old manure, to be repeatedly mixed in while the successive ploughings are going on, will materially aid growth if the land inclines to sterility. The owner need not deem it wasted labour to do several successive ploughings, for the more mellow the bed of soil is made the better it will be for the trees, and the easier will be the work of planting them.

Everything is now ready for final staking and planting. Take the cord already marked and stretch it from stake to stake in the middle of each ploughed strip of ground. Stretch it just enough to reach the opposite stake, and fasten it. Then proceed to stick in a small peg or corn-cob at every red yarn mark. The exact place for every tree is thus rapidly made, and when the whole ground is marked, it will be

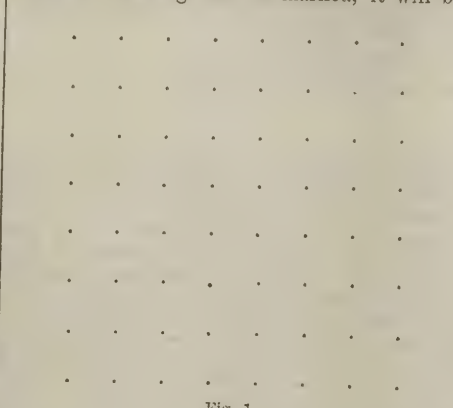

Fig. 1.

like fig. 1. Without stopping to look, they will all range perfectly both ways.

The next thing is to set the trees. A common and slow way is to set each tree by looking both ways with the eye, requiring much time and care, and often obtaining crooked rows in the end. But with the method here described no "ranging" whatever is needed; the work is

Fig. 2.

rapidly done, and the rows will be so straight, that in looking along them the first tree will hide all the rest. Next take a strip of board, say about 8 ft. long and 6 in. wide, as shown in fig. 2, and cut a notch in one side at the middle, just large enough to let in the stem of a tree. Bore a hole through each end exactly at equal distances from this notch. Then whenever a tree is to be planted, place the middle notch around the peg, and thrust two other pegs through the holes at the ends. Then take up the board, leaving these two pegs, dig the hole, replace the board, and set the tree in the notch. Proceed in this way till the whole orchard is planted. It is obvious that the trees will stand precisely where the first pegs were placed, and will range in perfect rows. A large number or series of the two pins may be set successively by the board, so that a number of workmen may be digging and planting at the same time.—*Country Gentleman.*

Pruning Bush Fruits.—The pruning season being close at hand, a few words on the subject may not be unacceptable. The Gooseberry, though undoubtedly one of the most popular of fruits, is nevertheless seldom managed as well as it ought to be. It may often be seen in the form of a stunted, starved bush, crowded with old, Moss-grown, unfruitful wood, or as a great, overgrown, ungainly bush, with nothing in the shape of fruit-bearing wood about it. In a general way, both these incongruities arise from mismanagement. Another form of mismanagement may be found even in some well-kept gardens, where the bushes are annually pruned into some symmetrical form, regardless of their fruit-bearing properties. The Gooseberry will grow and succeed well in almost any soil, but it does best, undoubtedly, on deep, rich alluvial deposits. Grown in such soils it sometimes becomes, as regards size, a tree. Given a good suitable soil and healthy plants to begin with, there ought to be no difficulty in keeping Gooseberry bushes always in a shapely form and bristling with strong, clean, healthy fruit-bearing wood. It is no uncommon thing in many gardens to follow the pernicious practice of cutting the young wood back to two or three buds—a system decidedly wrong, because it does away with a large amount of fruit-bearing wood, and also because the Gooseberry, being naturally addicted to making spurs, this system induces it to make many that have eventually to be removed. To avoid this, it is necessary to remove entirely all superfluous wood and to leave the leading shoots quite two-thirds of their length. At the same time all overcrowding must be avoided. Bushes treated in this manner rarely fail to produce heavy crops of fruit of the finest quality. It will also be found that they will bear well up to the very tips of the previous year's growth, an important advantage in cases where fruit is grown for profit.

Red and White Currants, as a rule, produce fruit of finer quality when spurred close in than when the wood is left at greater length. Therefore, the most satisfactory way of pruning these is to cut the current year's growth back to two buds. In places where sparrows do not pick out the fruit-buds Currant bushes may be pruned as soon as the leaf falls; but where these little depredators are plentiful it is perhaps as well to defer pruning until spring, unless, indeed, the bushes can be protected from their ravages by means of netting. Our method of pruning these is to entirely remove all the old and worn-out wood, also any superfluous young wood, always keeping an eye to the shape of the bush. The fruiting wood left is not shortened at all, or cut in any way, the great object being to have as great a quantity of strong, short-jointed wood as possible without overcrowding.

Raspberries ought now to have all the old fruiting canes removed, in order to allow a free circulation of light and air through the plantation, without which it is useless to expect the wood to ripen or the fruit buds for the ensuing year to mature. After the leaf has fallen the young canes will have become hard and firm, and will be in a fit state to be shortened. The length will have to be determined by the operator; it should be regulated by the growth which the plants have made, as should also the number of canes to be left. Where the growth is vigorous from five to seven canes, from 5 ft. to 6 ft. high, may be left; these may be slightly twisted round each other and bound at the top with a piece of Willow. The twisting causes them to break more regularly than they otherwise would do. Of course where Raspberries are grown as espaliers this twisting is unnecessary.—T.

Out-of-door Grapes.—The summer of 1879 was so sunless that few of the out-of-door Vine shoots of that year were sufficiently ripened to produce fruit-buds. But an exception has to be made in favour of Miller's Burgundy, which has, with me, produced a good many bunches, although small (they are generally small at the best), and which have ripened perfectly, and are ripening, in the present nice warm weather. The flavour of this Grape is exceedingly good, and Mr. Hoare, in his treatise on the culture of the Vine on open walls, truly describes it as "a very hardy and prolific Grape, and one which ripens perfectly in any season." It may be remarked in contradistinction that Sweetwaters this year, in consequence of the non-ripening of their buds during the last, are, as regards crop, a total failure. The Black Grapes, such as the Miller and Esperione and allied kinds, seem to be decidedly preferable to Sweetwaters and White Muscadines as regards fruitfulness in unfavourable seasons.—J. M., *South Hants.*

Autumn Crocuses.—This is a name applied to the autumn Meadow Saffrons (Colchicums) on account of the close resemblance of their flowers to those of the ordinary Crocuses. The genus Colchicum consists of hardy bulbs that flower in the autumn, just when summer-blooming plants have lost their freshness, and when the days begin rapidly to shorten. Unlike many bulbous plants, their presence in the ground early in spring, when the borders are being prepared for summer-flowering plants, is not likely to be overlooked, for after the flowers have disappeared in autumn, we find no trace of them aboveground during the winter months, but amongst the earliest harbingers of spring appear the vigorous leaf-stems, bearing three or more leaves, and carrying with them the seed-pod or capsule. It would hardly be possible for those who have not seen the various varieties of Colchicum in bloom to conceive how beautiful they are in the flower garden, and how valuable for prolonging the succession of flowers. In September and October, and even in November, the display produced by a good collection of Colchicums proves most attractive. Some of the varieties have beautifully chequered flowers, and most of them are so floriferous as to cover the ground with a sheet of blossom, and as the leaves do not appear till spring, at a little distance the effect is peculiar, there being nothing but colour. The best position in the flower garden for Colchicums in the mixed flower and shrubbery border, or separate little beds may be made on purpose for them, where they can be planted in carpets of Stonecrops (Sedums) or Mosses, so that the blooms will not get splashed with soil during heavy rains. All the species may be grown successfully in ordinary garden soil, but to have them in perfection, choose a situation fully exposed to the sun, with the soil of a sandy character; in fact, such a spot as is likely to dry up during summer—here they will luxuriate and enjoy the autumn, winter, and early spring rains. Colchicums may also be grown in pans or vases in the same way as the spring Crocuses, and they will also succeed in small vases of water like Hyacinths. They require to be planted in June, July, or August whilst the bulbs are at rest. The species and varieties most worthy of cultivation are C. autumnale, the well-known British species, with its many varieties, varying in colour from deep purple, rosy-purple, and rose to pure white, while some forms are more or less striped with white; the same species has also several very beautiful double forms. C. byzantinum, which we now figure, is a noble species, the petals of which are of good substance and very regular in outline—the whole flower most perfect in form. Of this species there is also a handsome form with variegated foliage, C. variegatum, and another very beautiful kind named C. Parkinsoni (figured in Gardening, October 11, 1879) has the flowers chequered in a manner somewhat similar to the Snakeshead (Fritillaria Meleagris); C. speciosum is probably the noblest plant of the family. It is a native of the Caucasus, and it is also said to inhabit the south-west shores of the Caspian Sea. Although this species varies a little in point of colouring, the annexed illustration in no way exaggerates the beauty of the plant or its size, but may be regarded as a good typical specimen; a few, however, are a little darker in colouring. Like C. byzantinum, it is exceedingly floriferous, as indeed are all the section more or less, each bulb throwing up many flowers. There are many other species of Colchicum well worthy of cultivation, but those just enumerated may be considered the best.

Autumn Crocus (Colchicum byzantinum).

Chrysanthemums in Pots. — Cold nights remind us that frost is near at hand, and that it is high time that even such hardy plants as Chrysanthemums should be safely housed, or be so stationed that they can be afforded temporary shelter to preserve their buds from injury should cold weather set in. In cases where they are removed to the shelter of glass, it should be where they can have a damp atmosphere surrounding them, such as is afforded by standing on the soil of an orchard house or Peach border, and if this be supplemented by an occasional syringing, the plants will be all the better for it. See that they are kept well supplied with liquid manure, and never allow them to become at all dry at the root, or the foliage will soon become shabby, and the blooms will not attain their full size or proper development. —J.

Wintering the Rice-paper Plant.—The usual mode of wintering this plant, Aralia papyrifera, is in greenhouses; even those used in the flower garden in summer are taken up in October, potted, and stored under glass. Such, too, is the safest plan, but where stock is plentiful, the plants strong, and have been growing out of doors during summer, the following plan, which is practised at Battersea Park, may be tried: Mulch the ground over their roots with leaves or litter, and twist a straw or hay-band around the stems of the plants. In spring, by pruning back to prominent eyes in the old wood, the plants soon start into growth and progress vigorously, amply compensating with large and broad leaves the care bestowed on them. As soon as all fear of hard frost in spring is over the bands may be removed.—W. F.

Calceolaria amplexicaulis. — This, though in some cases discarded from the flower garden, is, nevertheless, a most useful vase plant, its shade of yellow being so pure and delicate. This morning I measured some shoots about 3 ft. long hanging from the sides of a large vase of mixed plants. Tropæolum Lobbianum is a good companion plant to it, the shoots drooping almost any length. It is still the most beautiful of Calceolarias, and the most useful where its free habit is not objected to.—P. M.

TUBEROSES FLOWERING THE SECOND YEAR.

In the description of Tuberoses grown out-of-doors at Mr. Ware's, which formed the frontispiece of Gardening Illustrated of Sept. 25, I find that the idea of the bulbs being of little service after the first year of flowering is still adhered to. But as we have had them flower far better the second year than the first after importation, I venture to ask some of your readers to give the plan a fair trial before throwing the bulbs away, as is usually done, after flowering. That Hyacinths and similar bulbs do not flower well the second year after forcing is quite correct, as stated by your correspondent; but, considering the treatment they receive after flowering, this is not remarkable, as bulbs of all kinds that depend so much on fully maturing their foliage, and thereby laying up a store of organised matter in the bulbs for producing flower-spikes the following year, cannot be expected to flower if either deprived of their leaves altogether, or their chance of perfecting their growth almost destroyed by placing them either under half dark stages, or suddenly setting them out in the cold, or drying off before their growth is half completed. In fact, imported bulbs are treated, in the majority of cases, as if their term of existence was at an end as soon as they had flowered the first, for it is nothing unusual to find the sticks that are put to Hyacinth flowers inserted right in the heart of the bulbs, and probably piercing the bulb that would flower the next year right through. If they do not flower much the second year after this kind of treatment it is not anything remarkable, but rather that they maintain their vitality and flower at all. I could enumerate many good examples of more rational treatment, but sufficient to illustrate my meaning is the fact that many of the most successful growers of the much admired Lily of the Valley have forced the same roots several years in succession; but to do this they take the greatest care of the foliage, for one might as well expect our hardy Lilacs, Deutzias, &c., to flower well year after year, if treated like bulbs often are. They are all naturally free flowerers every year, and only fail under very adverse circumstances. But returning to Tuberoses, I may say that when our roots ceased flowering last year, they were placed on a shelf in a cool, span-roofed house, and gradually ripened off by giving less water, and as soon as they showed signs of growth in spring they were shaken out from the old soil carefully, and re-potted in rich, light material, and plunged in a Cucumber pit. They grew away rapidly, so that we gave a shift into larger pots, and as the summer advanced we gave plenty of air, with abundance of moisture at the root and overhead. As their flower-spikes pushed up we removed them to a cool orchard house, where they perfected very fine trusses or spikes of their wax-like flowers, three or four spikes of a dozen flowers each to a pot, and as they made equally good leaf growth as last year, I see no reason why they should not flower equally well next year, and any not required for pot culture will be tried planted out-of-doors, and next year I hope to report as satisfactory a result as that recorded at page 352.

J. Groom.

A Pansy Election.—The greater number of gardening amateurs have limited space, limited means, and few opportunities of seeing for themselves the numerous varieties of each kind of flower that they wish to grow. For these reasons a selection of a few of the very best varieties is at once their best policy and their most difficult task. They cannot see for themselves the hundreds of varieties of the Rose, the Pansy, the Viola, &c.; they cannot trust to

catalogues ; they probably know no one who is a competent judge from whom to obtain the information and guidance they need, and they have neither time, space, nor means to try for themselves one after another all the varieties contained in every nurseryman's list and stock. For these reasons you would confer a great boon on your readers by holding what are called elections, to settle the relative merits of the different varieties of each kind of flower. May I suggest that you should help your inexperienced readers by kindly undertaking an election for the class of bedding Pansies and Violas. It is of no use attempting to distinguish a Pansy from a Viola for this purpose, as it is often difficult to determine under which class some varieties should be placed, and it matters not whether the variety be a Pansy or a Viola if it possess the qualities needed. I would suggest that experienced persons be invited to favour us by recording their votes for the Pansies or Violas which they consider the very best for bedding purposes in answer to the following test questions : Which are the three best varieties of purple, of blue, of yellow, and of white? their merits or qualifications being determined by their possession of the following qualities : (1) long and continuous blooming ; (2) profusion of bloom ; (3) high quality of the individual blooms, both as to shape, colour, and size ; (4) robustness of constitution, enabling them to stand cold and heat, and ordinary soil, and needing no coddling or special care ; (5) dwarfness and compactness of habit, making them less liable to be injured by strong winds. It would undoubtedly be a great advantage to your inexperienced readers to know what 12 varieties were considered by competent authorities to combine all the above qualifications in the highest degree ; and also which variety of each colour was most generally voted to the highest place of excellence.—A Perplexed Lover of Pansies and Violas.

Pentstemon gentianoides.—This is the common garden Pentstemon bearing large panicles of purplish-red flowers during the summer months. It flourishes freely in light sandy soils, and forms full handsome bushes, but in wet clayey soils it perishes in winter. The florists' varieties of Pentstemons are, perhaps, better adapted to stiff cold soils than this.

HARDY FLOWERS FOR SMALL GARDENS.

(Continued from page 343.)

In the foremost rank of hardy flowers stand the Primrose and the Polyanthus. Their merits are too well known to need description ; at the same time I would observe that there exist many fine and distinct varieties of these charming spring flowers which do not appear to be extensively grown. Some few of them appear to need especial care, but the majority are of easy culture, are extremely hardy, and bloom most abundantly.

Primroses. — These are very pretty and effective, and comprise shades of crimson, purple, rose, yellow, lilac, and white, and it is easy to form by their means alone a most interesting feature in the garden. What they really need in order to grow them to perfection is a free, fairly enriched soil, and if accorded a position where they may enjoy positive shade they will repay such care by a luxuriant growth, increasing in strength and beauty with each succeeding year. P. cortusoides amœna is a charming plant, which should be in every garden. It has this year proved itself to be extremely hardy, growing with the greatest freedom, and flowering profusely in well-drained positions at an early period of the year. The foliage of this Japanese Primrose has an extremely fresh and verdant appearance, showing up to great advantage the numerous umbels of rose-coloured flowers which issue from it. This is one of the very first plants that an amateur commencing the culture of hardy perennials should procure, as it is no less distinct than beautiful. Primula denticulata is a pretty and interesting little plant of vigorous growth, with fresh bright green foliage and bluish-lilac blooms. It is a moisture-loving plant, and should be accorded a sheltered situation, as, blooming at an early period of the year, it is apt when growing in an open, exposed position to be much disfigured by heavy rains. P. capitata is an attractive kind, which flowers at a much later period and is worthy of a place in any collection ; and the beautiful P. japonica must not be forgotten. I should, however, mention that this latter plant is somewhat capricious in its likings, being liable in some soils and situations to die off in the winter. Those who are favoured with a nice, mellow, sandy, well-drained loam may hope to attain complete success in the culture of this handsome member of the Primrose family, taking the precaution, however, of protecting the crowns with a little litter during periods of severe weather. It is, however, more the combination of cold and wet than cold itself that is to be dreaded. Planting, therefore, in free, well-drained soil will do much towards securing good results in the culture of this plant. Another interesting and pretty kind is found in P. farinosa, a native species, forming dense tufts of silvery foliage. It should be accorded a damp situation. There are also P. luteola, involucrata, integrifolia, and scotica, all of them beautiful, and worthy of a place in any collection of hardy plants.

The Polyanthus.—This is a charmingly

Common Pentstemon (P. gentianoides).

effective plant, the presence of which would of itself suffice to render a garden gay and interesting in early spring. The Polyanthus has long been subjected to the manipulations of the florist, and many beautiful named varieties of it still exists, many of which, however, require some protection against the vicissitudes of an English winter, and which display their lovely markings to much greater advantage when afforded the shelter of a glass roof at the blooming period. I should, however, observe that it is not from cold that the plants suffer, but from the combined influences of cold and wet. A cold frame, therefore, is all that is needed to preserve them in health and vigour. The named varieties of the Polyanthus are rarely seen in good condition, and although growers are commencing to pay more attention to them, owners of small gardens who may not wish to be troubled with tender plants would find in the Polyanthus a fine subject for a hobby. A collection of two or three dozen kinds would afford much pleasure and occupation, and in yearly raising a batch of seedlings from them there would be the gratification of obtaining new and interesting forms, and there is always the chance of raising a new variety of sterling merit.

There would also be the advantage of obtaining a number of fine, showy flowers for the embellishment of the flower garden. Those who might desire to quickly work up a stock of plants for open-air decoration should procure a packet of seed of a first-class strain. Sow early in spring in well-drained pans of sandy loam and leaf-mould, two-thirds of the latter to one of the former, slightly covering the seed and placing the pan in a frame, and covering it with a pane of glass. When the seedlings appear, gradually inure them to full exposure, and when large enough to handle prick them out in pots of free soil, or in a bed of prepared soil in a frame. If planted thinly they may remain there until the latter end of August, when they should be placed in the positions which they are to occupy permanently. It will thus be seen that good, strong, healthy specimens will be secured by the commencement of winter, which, if they have been planted in congenial soil, cannot fail to make a brave display the following spring. If a frame cannot be devoted to them, prepare a nice bed of free soil in a cool situation, choosing, if possible, a position screened from the noonday sun, but where its morning and evening rays penetrate. Prick them out about 6 in. apart, and attend carefully to watering, sprinkling overhead at least twice a day in hot weather, as, unless the Polyanthus is kept cool and moist, it quickly falls a prey to red spider. Plants of choice kinds grown in pots of both Primroses and Polyanthuses should be repotted about the latter end of August, shaking away all the old soil, dividing the crowns, potting each one separately in a 4½-in. pot, or if larger specimens are desired three may be put into a 6-in. pot. A compost of two-thirds turfy loam to one-third leaf-mould and well-rotted manure suits them well. Water moderately for a time, and place in a cool situation until well established, when copious supplies of water must be given, and by the latter end of September the plants should be brought out into the full sun, there to remain until the latter end of October, when they should be placed either in a cool greenhouse or in a cold frame, giving air freely throughout the winter on all favourable opportunities. This treatment will result in the formation of well-developed, robust crowns, capable of producing vigorous stalks bearing blooms of surpassing quality, the grower having as a reward for his pains the pleasure of seeing a brave display of these beautiful spring flowers some time before they come into bloom in the open air. It has always been a matter of considerable surprise to me that the Primrose and Polyanthus should not be more generally grown for conservatory and room decoration.

They need no forcing, the protection which they receive being alone sufficient to bring them fully into bloom at a time when our gardens are comparatively bare of colour. Even those who have no glass accommodation whatever may manage to enliven their dwellings with them at an early period of the year. Grow them as above advised, and on the approach of winter plunge the pots quite to the rims in ashes in a sheltered situation, protecting the crowns in frosty weather with a little litter. About the middle of January clear away all the old foliage, and place them in a cool room, and they will come finely into bloom. For windows having a north aspect it is difficult to find flowering plants that will grow into beauty

in early spring. The Primrose and Polyanthus delight in a cool, sun-secluded situation, expanding their pretty cheerful blooms quite as freely as if placed in a lighter position, and lasting a long time in perfection. Two excellent varieties of the Polyanthus, either for bedding purposes or for pot culture, are Early Admirable and Golden Plover, the former being a rich crimson, the latter golden-yellow; the effect which they produce when massed is very fine indeed. Those, however, wishing to form a collection of named kinds must consult the catalogue of some firm making a speciality of this class of plant.

Pinks.—Another beautiful flower to which I would direct attention is the Pink. I feel quite sure that were it more generally known that so many charming varieties exist of this old-fashioned flower some of them would be found in every garden. The inclination which has of late years prevailed to fill our gardens with flowers of brilliant hue is probably the cause of their being so little grown. Let us, however, hope that a more refined taste will in future guide the operations of those interested in flower gardening, and that we shall see these pretty, free-flowering subjects, with their chaste, refined colours and delicate markings, fully reinstated in public favour. Unlike their near relations, the Picotee and Carnation, many of which are of delicate constitution, they are by no means fastidious with respect to soil or situation, a fact which renders them of great value to the owners of villa and suburban gardens generally, who often suffer under considerable disadvantages in this respect. In any case, however, the soil should be well worked before planting, and if of a heavy, retentive nature, it should be lightened by the admixture of some river sand or leaf-mould. Good, healthy plants procured now and planted carefully will get well established by the winter, and will flower freely next year.

J. Cornhill.

(To be continued.)

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

October 18.—Potting Tropæolum Jarratti, Charles X. Lilac, and Kalmia latifolia, also Lilium speciosum (lancifolium) album and rubrum in peat and sand, late Stocks for winter flowering, and Echeverias from borders; planting bulbs in flower beds, Brier Stocks for budding, and Box for edgings; removing Centaureas from flower garden and plunging them in a cold frame; taking up Dahlias, the tops of which are all killed; taking up Endive and putting it where it can be protected; shifting double Wallflowers into 6-in. pots; nailing Currants and Gooseberries on walls; putting Chrysanthemums into conservatory and all Strawberries in pots under cover; gathering all Scarlet Runners which are fit for use; taking up Carrots and Beetroot; thinning some of the inside shoots from Nut trees; hoeing among young Strawberry plants; cleaning Asparagus beds.

Oct. 19.—Sowing Nemophila and Saponaria in pots; planting Wellingtonias, standard Roses, Hollies, Wallflowers, Silenes, and Tulips, also planting Lettuces under the protection of a hedge; washing Orange trees; sweeping centres of walks to keep leaves from being trodden in the gravel.

Oct. 20.—Potting variegated Dactylis for flower beds; putting a few more Primulas into 8-in. pots; taking off Chrysanthemum layers; putting some Pears in a warm place to ripen; getting all Strawberry plants, Pinks, and Carnations stacked; taking up Lettuces and putting them under protectors in front of south wall; washing a Fig tree infested with scale with soft soap; top-dressing Peach house outside border with ½ in. of bones, short manure, and loam; trimming up conservatory creepers.

Oct. 21.—Potting Forget-me-nots for flowering in pots; planting Feverfew, also Aubrietias, Arabis, Alyssum, and Pansies in beds; examining the roots of Cherry trees, giving them some new soil; getting all Pelargoniums from frames, &c., into house; placing old roots of Salvia patens in boxes, and putting them under stage in back pit for cutting in spring; sending in Raspberries, also Marie Louise Pears, and gathering Josephine de Malines and Glou Morceau; top-dressing second Peach-house border with half-a-bag of bones, short manure, and loam; earthing-up July-sown Cabbage.

Oct. 22.—Potting layered Carnations, also Lily of the Valley for forcing; putting long straw over Laburnums in pots for forcing, and plunging Rhododendrons for the same purpose in straw; taking up Bath Cos Lettuces and putting them under protection; protecting Cauliflower heads by tying the leaves over them; beginning to nail Morello Cherries; putting straw round Violet frames; top-dressing early Vines with good loam, bones, sand, and horse-droppings; turning manure for Seakale forcing; gathering Easter Beurré Pears.

Oct. 23.—Planting Nemophila, Limnanthes, and Silene in flower-beds; manuring Roses; earthing-up Celery for the last time when the weather is dry; giving Calceolaria cuttings a little air, and only shading them for about an hour at noon.

Flower Garden.

At present by far the most interesting portion of the flower garden is the mixed, or what is generally termed the herbaceous borders; for, though many kinds of flowers are over and beginning to look weedy, others, such as Michaelmas Daisies, herbaceous Phloxes, Anemone japonica, and Stocks, are likely to keep up a succession till severe frost destroys them; meanwhile a little extra attention in the removal of weeds, decayed flowers, and fallen leaves will add to the fuller enjoyment of such flowers. As soon as the leaves are off the trees, and there is no further likelihood of litter on that account, the borders may be lightly forked over, and any plants the stock of which it is desired to increase may then be divided. Most kinds will bear division with impunity; at the same time it is well to remember that, as a rule, established plants flower most profusely; therefore, except for the purpose of increasing the stock, or preventing encroachments, such division is undesirable except at rare intervals. Plants on rockwork requiring re-arrangement or propagation by division may also now be carried out in their case. Sub-tropical plants that are intended to be preserved ought now to be housed. Those having no accommodation for wintering large plants of this character must depend for a supply solely on seedlings raised in January and February, and therefore the plants can be left in the beds till the frost has done its worst. Up to last winter Cannas wintered safely in the beds in which they grew with the protection of bracken, but all were then killed; they will therefore this season be lifted and wintered in a shed, from which frost can be excluded. Abutilons are worthy of being housed early, as if placed in an intermediate house they soon re-establish themselves, and are invaluable for the production of flowers at a season when they are scarcest. Draccenas and Palms are also valuable for indoor winter decoration, and these too should be taken up early.

Though we have not yet experienced any sharp frost, it will not be safe to risk out any longer tender bedding plants which are intended to be preserved. All the fine-foliaged Pelargoniums are most susceptible of injury, and if at all frost-bitten wintering them safely is a difficult matter. All other bedding plants which have been propagated for stock ought now to be housed, but they should have as much ventilation as it is possible to give them whenever the weather is favourable. Damp is their greatest enemy, and as the careless use of the water-pot tends to engender such damp quite as much as atmospheric conditions, this should be avoided. There is now such a wealth of plants suitable for filling beds in winter, that empty or bare beds ought not to be thought of; a list of some plants most suitable for this purpose was given in a former note. Our hope is that very shortly summer bedding will be so largely composed of hardy plants that but little supplementary planting will be required for the winter season. If this were the case the strongest objection that is with good reason advanced by the opponents of summer bedding, viz., its transitory character, would be done away with.

Auriculas.—Hardy Alpine Auriculas make very beautiful spring flowering plants in the open borders. They may now be planted in an open position, but they had better not be where the sun shines too much upon them. It would not do much harm at present, nor in early spring, but as the plants are intended to remain all through the summer months, it is at that season when the sun's rays have an injurious effect upon them. The soil should be good and well trenched, placing some well rotted manure from 6 in. to 1 ft. below the surface. In planting it is very desirable to place some good fresh maiden loam round the roots if it can be obtained; if not, the plants will succeed without it. Many complain that such plants as Auriculas disappear from the flower borders during summer; the heat and drought are blamed for this disappearance. No doubt Auriculas do not like to be exposed to a flood of sunshine during summer, but they will live and thrive through this rather than be suffocated by Verbenas or zonal Pelargoniums, which cause not only the death of these beautiful flowers, but of many others besides of similar character. Weakly-growing herbaceous plants used to thrive well in borders, and they do so now when they are protected from the devouring influences of bedding plants mixed amongst them in summer.

Carnations and Picotees.—Continue to pot off rooted layers of these as soon as they are ready, and if but few roots have been made the pots should be kept in a rather close frame, and be shaded from the sun until they are established. Those intending to purchase Carnations and Picotees should now do so; they move best at this season just as they are taken from the parent plants.

Hollyhocks.—Seedling plants should now be put out without delay, so that they may become established before the winter. Not only Hollyhocks, but also many other hardy plants, often suffer from inclement winters, owing to their not being established before frost sets in. Much depends, too, upon the state of the ground, the surface of which should be kept loose and dry by being frequently stirred up with the hoe. A close, hard surface sometimes causes an unhealthy growth through the sourness of the soil. These remarks apply to all classes of hardy florists' flowers put out in the open ground.

Pansies.—Hardy plants in pots increase almost too fast, but it is nearly impossible to resist the temptation of trying to grow a frameful under glass. Last season it was late before our plants were put out in the beds, and they did not do well; quite two-thirds of them were killed in winter by the frosts and wet combined. Had they been well established before winter probably not one would have been injured. We will grow one of each variety in pots, and probably the others will be placed in boxes and be kept under glass to be planted out in February or early in March as the weather may determine.

Glasshouses.

Eucharis.—Amongst large white flowers where a continuous supply is wanted, there are few, if any, that equal the Eucharis, especially the well-known E. amazonica. No matter how extensive the stock may be, it is necessary to vary the treatment with portions of it, so as to ensure a successional supply of bloom, otherwise it is quite possible that, even with a moderate-sized houseful of it the cultivator may find himself at times for a considerable period without so much as a single flower, whilst at other times there may be many more forthcoming than are needed. During winter the flowers are of most use, and if the portion of the stock that bloomed and made growth early in the season, and have been kept sufficiently dry with more air, so as to check further leaf production, are now put into a brisk heat, they will very soon begin to throw up flower-stems. By similarly treating another portion, so as to induce rest for the next two months, they will by the close of the year be in a condition for forcing, the flowers they produced keeping up a supply till spring is well advanced. It is only by treating this plant systematically that its blooms can be had at the time wanted. Independent of the value of its flowers for cutting, the purpose for which it is most generally grown, where blooming plants are required to occupy small vases and similar contrivances, there are few plants so effective as single bulbs of this Eucharis grown in 6-in. pots; the four or five healthy leaves from which spring a single stem of flowers with which a well-managed plant is furnished have an effect so employed such as few other subjects are capable of producing. The flowers will keep on the plants in a temperature of an ordinary living room for ten or welve days. and even when the weather is cold this Eucharis suffers less than most tender plants so treated.

Ardisias.—These, which are amongst the best of all berry-bearing plants, are, in many cases, late in getting the berries fully coloured this year, and in order to accelerate this they will require keeping in a little more warmth than would be necessary during ordinary seasons; but they must not be kept too hot, or frequently when submitted to a lower temperature the berries fall off prematurely. Plants raised from seed, or in spring from cuttings, must not be allowed to stay in the little pots which they occupy too long, as the best system of cultivation to follow with them is getting them up to a sufficient size without delay; for if they get into a stunted, slow-growing state they almost invariably lose their lower leaves, the effect of which is to make them so unsightly as to necessitate their being headed down. The tough, hard texture of their leaves is such as to guard them

much better against the attacks of insects than many plants, yet nevertheless if affected with aphides whilst the foliage is young its free development is stopped. Healthy leaves are requisite for the satisfactory appearance of all plants, even in the case of those that are grown for their flowers; but with these Ardisias, as with all other subjects cultivated for their foliage and berries, it is doubly essential that the leaves should be perfect.

Bouvardias.—The present treatment of these will require to be regulated by the time the flowers are required. So manageable are they, that little difficulty is experienced in getting them into bloom whenever wanted. As a matter of course, the strongest plants, such as grown from cut-back stools which bloomed last year, will be the furthest advanced in growth and in the best condition for blooming first; they will bear as much heat as most things, and, where the plants are really strong, will furnish through the winter greater quantities of flowers in succession when submitted to a brisk heat than where treated to an intermediate temperature. Plants like these, in common with others that make some growth through the winter, will be benefited by the application of manure water at short intervals; not only will it assist the development of the first flowers, but also those which come later upon the after growth. A portion of the stock of Poinsettias, Plumbagos, and Eranthemums will now need removal to the forcing pit where a structure of this description is at command, and where not available room must be made in a warm greenhouse, as a moderate heat is necessary to bring them in at the time required, as also to enable such plants as the Poinsettias to attain the full size which in many places is required. Although they will bloom with less heat than is usually present in a general stove, still they are never so fine under the cooler treatment. See that the whole stock of all these plants is perfectly free from insect pests of all kinds, for, with plants like these, that it is necessary to keep in warm quarters, insects, if present, increase apace; they also interfere with the flowering, and entail no end of labour to keep them down. In addition to the above, a portion of any others grown to flower during the winter should likewise be placed under the conditions of heat that will bring them on.

Fruit.

Fruit gathering will soon be at an end, and the fruit room will require careful management till all the fruit has undergone the "sweating" process, which invariably takes place during the first week or two after storing. Keep the ventilators open night and day (unless the weather is excessively wet), and as soon as the fruit seems dry, and has got thoroughly inured to the temperature of the room, then ventilate for about a couple of hours every fine day, and close up during wet, fog, and frost. The fruit should be stored as thinly as space will allow, both to insure its better keeping and to permit its being examined for the purpose of removing any that have begun to decay. Any specimens that it is desired to keep for exhibition or other special purposes should, when thoroughly dry, be wrapped up separately in tissue paper, and placed in drawers or boxes with the view of excluding atmospheric influences as much as possible. The weather is now most favourable for planting, root-pruning, and top-dressing.

IMPROVING CLAYEY SOILS.

I HAVE repeatedly seen paragraphs in GARDENING complaining of clay gardens and the difficulty of working them. The usual proposed remedy has been ashes and once-burnt earth, but there is a plan about Ludlow which is much used on the heavy clays, and which may throw a light on the subject. The farmers in a dry time, and on their fallows, usually pare and burn the headlands, putting the combined soil and weeds in small heaps, and when both are sufficiently dry setting them on fire, and letting them smoulder quietly until burnt out. The remnants of black clay soil are then spread over the ground with most fertilising effect. Some years ago I read of a plan to take the adhesive properties out of the clay permanently, and it was this: First drain the garden thoroughly to the depth of 3 ft. or 4 ft. If fall sufficient can be obtained, then on an elevated part place dry chips and small bits of wood in a long shape, like a Potato barrow, on the roof of a barn. Upon the wood place a layer of the garden clay, and upon that another layer of wood, and so on until the whole heap has reached a reasonable height. Then let the wood be ignited, but in such a manner that the mass should burn slowly, for a fierce heat would convert the clay into what is called about here clinkers, which would spoil all. When the whole has gently burnt out, the residuum will be black burnt clay, which will never become sticky or heavy again, but a nice soil with plenty of stamina to grow seeds, flowers, or trees. Not long ago I consulted a practical brick-maker about the feasibility of this plan, and he answered promptly that it would be quite easy to do, and moreover would answer. This plan can be tried on a small scale at first by any one afflicted with a strong clay garden, and the best plan to adopt would be to employ a regular brick-burner, so that there may be no mistake, and if successful, of which I have little or no doubt, will extricate many from a vexatious dilemma. F. NASH.

TREES AND SHRUBS.

Clothing Bare Places under Trees.—Grass will not grow well under a dense shade; even when frequently renewed the result is unsatisfactory. Yet, in conspicuous positions, the bare earth has an objectionable appearance, and the substitution of something of an evergreen character becomes a matter of importance. Whatever is chosen must either have a creeping habit, like that of Ivy, throwing out roots wherever the branches come into contact with the soil, thus always maintaining a clean, fresh appearance, or else like the Periwinkles, be able quickly to renew themselves from their base. Take, for instance, either the large or small Periwinkle; masses of either of these usually look worn and shabby towards the end of March, but trim off the discoloured growth and foliage, and in a short time they will be beautiful again; and if any light at all reach them, they will flower in the greatest profusion. There is scarcely anything so good as Periwinkles for covering shady banks where the soil is of an inferior description. Even Ivy takes some time to establish itself in bad soil, but the large Common Periwinkle (Vinca major) will grow in anything and almost anywhere. One of the creeping-rooted St. John's-worts (Hypericum calycinum) will also grow well in shady positions; once get it established, and cut it back occasionally, and it will give no further trouble; but all leaves that fall upon and are buried amongst its branches, or that are drifted by the wind, if not absolutely unsightly, should be allowed to remain for the purpose of affording nourishment. Euonymus radicans variegatus will likewise grow in shady places, and when planted somewhat thickly and pegged down it soon forms a close carpet. Lomaria spicant I have also seen do well in woods, where the shade of the foliage was heavy, and very pretty and interesting it looks growing in masses, and it will transplant with safety. Where a less formal growth is admissible the common male Fern (Lastrea Filix-mas), or the Shield Fern (Polystichum angulare), looks well in summer, but the former is not evergreen, and would not suit where a covering of that kind is desired. Several species of pretty close-growing Mosses are found naturally under the thick shade of trees; and where they thrive no better carpet need be sought, as they possess the advantage of always looking fresh and green. The Woodruff (Asperula odorata), when naturalised under the smaller kinds of Conifers, such as Arbor-vitæ, or any other close, low-growing evergreen, has a very good effect. But this, and, indeed, all other plants that may be used for the purpose of forming a close undergrowth, should be given a fair start. It often happens that the soil under large trees is thoroughly exhausted, and to plant in it without some addition would probably be useless; first break up the surface as far as can be done without injuring the roots of the trees, and then spread over it 3 in. or 4 in. of good soil; there would then be a chance of the plants used becoming established before the roots of the trees monopolised the fresh soil, and when well established they would be able to hold their own in the contest. Wherever Ivy is employed, and there is nothing that looks neater or is better adapted for making quick growth, either under the dense shade of the Cedar of Lebanon or the heavy drip of the Beech, it should be kept from climbing the trees if they are choice and valuable specimens; and where fresh soil is applied as a top-dressing in which to plant, it should be placed quite close to the trunk of the trees.—H.

Warning to Buyers of Evergreens, &c.—My attention was called lately to a man selling small evergreens, viz., Aucuba, Box, Arbutus, &c. I felt inclined to buy a few, but hesitated; my hesitancy saved my pocket. My neighbour bought three for 1s.—she was about to pot them for the window. I saw that she had not broken the ball of clay that was around the lower part. I called her attention to it, and said that I would pot them for her. I proceeded to do so. On removing the ball I found a quantity of half decayed Moss tied round the part where the roots should be. I removed the Moss, and to my surprise I found that the plants were merely cuttings inserted into the centre of a root of Plantain—quite a sell. The man had vanished.—JUSTICE.

The Golden-leaved Elder.—This is one of the best of coloured plants for enlivening shrubberies, but it is frequently condemned for its inconstancy in colour, particularly when it attains a considerable size. It is in this respect like many more self and parti-coloured plants, that it shows itself to the best advantage when in a young and vigorous state. It is, however, easily propagated, and when rooted grows so luxuriantly that, considering the purpose for which it is required, it need never be allowed to arrive at any great age or size. I find, moreover, that large plants of it can be kept up to the colour standard by winter-pruning the shoots to within a few inches of where they started from the preceding spring. I know a large plant that used to be grand in colour, but last winter it was left unpruned, and now, in consequence of such neglect, it is almost green.—G. S.

Trenching and Subsoil Manuring.—Heat and moisture being necessary conditions for production, we are greatly at fault in garden culture. If we are found complaining of the first, a cold sunless summer like that of 1879 tends to bring us to our senses, and ask ourselves, not why heat brings vegetable growth to a standstill, but why we do not turn it to profit when we have got it. "E. H." answers the question how—by deep cultivation and manuring to the full depth of the cultivation. How much poor shallow work is done! How fearful men are of the manure washing away through the soil! How little apprehension of the extent to which roots will descend. I see allotments dug with steel forks from which 4 in. of the tines have worn away, the subsoil never stirred, manure just covered over, fruit trees manured as if they were planted in boxes, and this on a dry, porous soil, when roots from an Apple tree have been found on the chalk 20 ft. from the surface. Such things are seen, and the lesson they teach is not learned, even by the man who finds those roots. When soil is enriched deeply, not only do roots find both moisture and food below when they cannot above, but the subsoil retains moisture in proportion to its enrichment. On the plot at Rothampstead, manured every year with farm-yard dung, the outflow of water from the drains is greatly diminished by the great power of retention conferred by that enrichment of the soil. For some crops subsoil manuring is absolutely necessary to make them worth growing. How common a thing is a poor crop of Parsnips, even on soil in good condition! My mode of proceeding is this: A trench is opened two spits wide, and shovelled out 1 ft. deep. The bottom of the trench is then rough dug as deep as a long-tined fork will dig it. Sewage is then poured in in quantity. Three or four poles are thus treated every autumn. I need hardly say that the plants give sufficient sign when they reach the subsoil. We lay bare the crowns, and pull them up with a leather strap and buckle. The effect of deep preparation for the Potato crop is not half realised; the difference of ten days' quick growth in hot, dry weather at the end of June, in place

of a ten days' stan still from drought, may mak all the difference with early kinds between a fai crop and a half-g- own one when the disease appears, and so by dishaulming to get not only a sound, but abundant yield. In this, as in many other ways, there is no time to be lost. We have not only "to make hay," but to grow vegetables "while the sun shines," and the hotter the better, so that we bring moisture as well, or take the roots to a moist food bed.—J. M. Taylor.

GLASSHOUSES AND FRAMES.

STEPHANOTIS FLORIBUNDA.

Although specimen plants of Stephanotis are not uncommon, yet it is much more generally grown wholly for the sake of its flowers in a cut state, their pearly whiteness and delightful fragrance rendering them favourites for nearly all kinds of indoor decoration. When its blossoms are required in quantity the best plan is to plant it out in brick compartments or narrow borders, and to train the shoots tolerably close to the glass, for unless a maximum amount of light and air be given it, it will not flower freely. The most floriferous plant of Stephanotis which I ever had was planted in a narrow border not more than 1½ ft. wide, in a compost of fibry turf, peat, and sand, resting on a quantity of brick rubbish, which acted as drainage. Here it had abundance of water, both at the root and overhead. It is very liable to be attacked by mealy bug, but copious deluges of tepid water will dislodge it. The shoots were trained horizontally on wires 8 in. apart and the same distance from the glass of a span-roofed pit, where they could receive abundance of heat, light, and air, but where they were at the same time carefully shaded from the direct rays of the sun while the foliage was in an immature condition during the early summer months, and while the principal flowering season lasted. During the autumn months they received all the light and air possible, with but an intermediate temperature, and during the winter months the temperature was seldom more than 50° at night, and sometimes even lower than that, but as sunheat increased with the lengthening days in early spring, and more fire-heat was applied for forcing purposes, the flower bunches appeared at the axil of every leaf, so that by the time they began to expand, each wire looked like a bridal wreath, densely furnished with waxy flowers of great substance. While in that condition it was copiously supplied with weak liquid manure to help the crop of bloom and to promote some early growth, that usually flowered well later in the summer. As this plant was confined to the portion of roof over the central pathway, it occupied space that could not well be otherwise utilised; but if trained thinly over an entire house or pit, the majority of plants, such as Ferns, that delight in partial shade, might be grown under it with advantage. Where a narrow border is not available, brick compartments would be preferable to planting it in a large body of soil, more especially where it happens to be associated with stronger-growing plants. Thus treated, the roots are more under command as regards the applying of moisture, and when any lack of vigour is observed the old soil can be carefully removed from the surface and replaced with fresh, well-enriched compost. Any pruning required should be done after the flowering is over; it should consist in cutting any old, bare pieces away in order to give light and air to the new growth; overcrowding, above all things, must be avoided. Plants grown on circular wire trellises frequently fail to flower freely, owing to the young wood being trained so thickly as to be unable to get ripened. In that case it should be trained up thinly on wires until thoroughly matured, and then be replaced on the trellis, when it will be almost certain to produce an abundant crop of flowers. J. G.

Luculias.—In the genus Luculia there are only two species, viz., L. Pinceana, which we now figure, and L. gratissima. L. Pinceana is at present as rare in cultivation as L. gratissima, is common, yet it is equally beautiful, and is even said in some respects to excel it. There is a remarkable similarity in both species, so far as regards general appearance; but L. Pinceana has broader and shorter leaves than the other, and differs from it materially in botanical characters. It was raised from seed received from Nepaul by the late Mr. Pince, of Exeter, in compliment to whom it was named; but although nearly forty years has elapsed since its introduction, it is rarely to be met with in gardens. There are some fine specimens of it in one of the greenhouses at Glasnevin. Its lovely pink blossoms, borne in large trusses, and the delicious and powerful perfume emitted by them, render it a plant to be desired by everybody for growing in a cool greenhouse. Both kinds like a good body of fresh open compost, in which its roots luxuriate, spreading in all directions; still, one occasionally meets with nice little specimens in tubs, but even these would be much better if planted out. A little weak manure water is very beneficial to these plants when making their growth, more especially when their roots are confined. If regularly syringed, and a genial temperature maintained, Luculias are rarely troubled with insect pests; while any little extra attention bestowed upon them is amply repaid when their flowers make their appearance. We have no other plant that rivals them for winter blooming in the conservatory. The plant is readily propagated by means of cuttings or layers inserted in a sandy compost in a genial bottom-heat, and when the young plants are fairly established, they develop themselves very rapidly. The plant does well in a large pot or tub, but if it is planted out in a good fresh

A Beautiful Winter-flowering Greenhouse Plant (Luculia Pinceana).

compost of fibrous peat and turfy loam, it develops itself far more rapidly and requires no further attention than occasional syringings and a good supply of water at its roots. The great clusters of sweet scented flowers of Luculias are generally produced in winter, and this makes the plant doubly valuable, as choice flowers are then generally scarce. The plant should be pruned in about the middle of March, and will soon start into growth, especially if assisted by gentle syringings on warm days. Every encouragement should be given to induce it to make its growth early and quickly, so that the young wood may get thoroughly well ripened in the autumn, as this conduces to large clusters and a far finer crop of flowers. A warm sunny position should be selected, and the compost should be placed on a well-drained bottom.

ROSES.

Dwarf Roses on Seedling Briers (Treatment of the Briers). — Briers which have been raised from seed this year (see Gardening, December 20, 1879) should be transplanted from the seed-beds or drills in which they were grown about the end of October. Transplant into rows 2 ft. apart, and 1 ft. between the plants in the rows. As seedling Briers are budded below the collar of the root, the plants must not be inserted so deeply in the ground as when growing in the seed-bed. After shortening the tap-root, plant them so that the collar of the root may be about 2 in. above the level of the ground. It is on this portion of the root that the buds are inserted in July and August. The operation of budding is rendered more easy by setting the collar of the root a little above ground (as described), but buds may be inserted below the collar on plants not so raised by removing the earth from about the root. One or two buds may then be inserted, and at the approach of winter, having made sure that the buds have taken, the ties may be removed and the earth filled in about the buds, to be again removed in spring when the frosts are over. Roses thus formed producing roots from about the callus of the bud may become Roses on their own roots.—Ombu.

Manuring Roses.—Roses require feeding. The more food the richer the colours, the larger the size, the more solid the texture, and, more marvellous still, the sweeter the fragrance. There is, however, a proper time for manuring Roses. Many give it too late in the season; they seem to imagine that when the strain is heaviest on Roses or other plants, that is the time to assist them with stimulants, and so it would be could the stimulants get at them, but it takes a long while for solid dressings applied at the root to reach Rose leaves or flowers. Even liquid manure, of which we are accustomed to speak and write as if it acted at once, takes days, weeks, and even in some cases months, to reach the points where it is most needed in our Rose trees; while as for solids, they have to undergo no one knows how many processes of comminution and chemical decomposition, and perhaps recomposition, before one particle of their strength can go to support the Rose either in its efforts at growing or flowering; hence the best time to manure Roses is, probably, November. Winds, rains, frosts, snows, sunshine and showers, heat and cold, all these prepare the manure for the plants and assist the roots to absorb it. The roots, too, are also abnormally active during winter; they never cease absorbing unless when frozen, and then during the winter and early spring the manure may be turned in or out, or tossed about in any way best suited for the Roses, without creating much or any annoyance to any one. Under such circumstances, Roses feed at their leisure all the winter, and are well furnished for their work before their flowering season in June. On the same principle, even manure-water should be applied early. March and April are much better months for saturating Rose beds with sewage and other manure water than May or June. Water is no doubt quickly absorbed, but it is exceedingly doubtful if the manure can be appropriated by the plants in anything like the same time; or whether, in fact, it does not really take a long time to convert any of the strength of the manure into Roses. Besides, it is of the utmost importance for the proper enjoyment of a Rose garden that it should be kept sweet and clean throughout the flowering months. What are called surface-mulchings might also generally be dispensed with. They are mostly composed of some loose, unsightly material of slow-conducting powers, to keep the moisture in and the heat out. But a loose surface of the soil itself would answer either purpose as well or better and prove at the same time neat and sweet. Roses are also often rendered disagreeable through the application of insect remedies of various sorts—such, for instance, as Tobacco-water, sulphur and Scotch snuff. All such dressings should be forbidden. Only three remedies against insect pests are at once effective, cleanly, or pleasant. These are the finger-and-thumb cure in the early days of the grub or aphides, heavy washing with clean water from a powerful garden-engine or doses of carbonate of ammonia, or smelling salts, applied with a sponge or a small squirt. This last destroys the insects, adds a new perfume to the Roses, and seems to invigorate the growth and enhance their beauty.—D. T. F.

Soil for Roses.—Opinions differ very much about the soil and situation for Roses, but some of the best Roses I ever saw were grown on a hill about half a mile from where I am writing. The hill is considered to be as high as the highest hill near Buxton, in Derbyshire, and fully exposed to all winds, and the soil is light and stony, being where stone quarries are worked.—J. M. G., *South Yorkshire.*

Prizes for Fruit.—At the Maidstone Chrysanthemum Show, to be held in the Corn Exchange, Maidstone, on Nov. 19 next, there is

prize of £5 5s. offered for the best eighteen plates of Apples (distinct kinds), open to all England. We also notice that a prize of £10 10s. is offered for thirty-six blooms of large-flowering Chrysanthemums, open to all comers. Schedules may be had of the Rev. C. Shepherd, Trottiscliffe Rectory, Maidstone.

House and Window Gardening.

GROWING HYACINTHS IN GLASSES.

As a rule it is not well to put Hyacinths in glasses too early. After growing Hyacinths in glasses for many years I have come to the conclusion that it is well to select the bulbs early, taking care to have them sound and not too large for the glasses, and then put them in a dry and cool place until the ring at the base of the bulb shows signs of swelling, owing to the inclination of the incipient rootlets to become active. As soon as this occurs the bulbs should be placed in contact with the water. Some sorts root much more freely than others; among the latter may be included the deepest coloured reds. Robert Steiger is a charming variety for a glass, but it does not always root well, and I have tried the effect of placing the bulbs for a time on some moistened Cocoa-fibre, and so induced them to start into growth before the bulbs are brought into contact with water. They should not be allowed to remain in the fibre after the roots have gained the length of from ¼ in. to ½ in., as they then begin to take an outward direction, and a little difficulty is experienced in getting them into the glasses, as they are very brittle at that stage of growth.

Now as to the glasses. Let us hope that the old, tall, upright chimney is now quite abandoned. It is ugly in shape, common in appearance, and top-heavy with the weight of the spike. The support for fixing the spike is a clumsy contrivance, and always unsatisfactory. When the late Mr. G. P. Tye, of Birmingham, introduced his registered Hyacinth glass many years ago this difficulty was obviated, for while it was well suited for the growth of Hyacinths in water, it was also an elegant chimney-piece ornament, and well suited for holding cut flowers in summer. Hyacinth glasses are now manufactured of various materials and in handsome designs, and having supports well suited for the purpose for which they are intended.

The tendency of the water in Hyacinth glasses to become putrid is a difficulty with many. I have found it of great value to place in each glass a few small pieces of charcoal, and this seems to keep the water sweet. The glasses are filled up sufficiently high with clear fresh rain-water, and the charcoal is dropped into it. Then the bulbs are placed in the glasses, allowing the water just to touch the base of the bulb. Rain-water should not be employed unless quite fresh and clear, or otherwise it soon emits an offensive smell, and causes the roots of the bulbs to decay. If there is no alternative but to employ hard water, it should be exposed to the influence of the sun for a day or two previously. The glasses can then be placed in a cool dark cupboard or closet, or in a dark cellar for a time, to induce them to root downwards before they begin to make an upward growth. I do not think this is so necessary as is generally supposed, but it is so constantly recommended that one can hardly be an exception to the rule. I have grown very fine Hyacinths in glasses without placing the glasses in the dark, but I always prepared the bulbs for the glasses as above recommended.

There are many failures with Hyacinths in glasses, but it is not the fault of the bulbs, but of the indifferent treatment they receive. Two causes operate to bring about a failure, viz., keeping the glasses in too warm a temperature, and refraining from giving the necessary supplies of water. Perhaps there is one advantage after all in placing the glasses in the dark for the space of six weeks or so, namely this, that during that time the bulbs, when least interesting, are subjected to a uniform temperature, and do not get unduly excited into growth. When the glasses are brought to the light they should be placed near the window, where plenty of light and air can be given them. After Christmas the growth will be rapid, and the prime requisites are to keep the plants growing sturdily, to take care they do not become drawn in the foliage, to have the water sweet and wholesome at the roots, and to keep the water in the glasses up to the base of the bulbs. As soon as the spike of flowers becomes tall enough, the support, which can be bought with the glass, should be placed in position, and as the spike lengthens the supporting hook should be raised to the necessary height.

Hyacinths in glasses are, as a rule, badly managed in the extreme, for it is not unusual to see a spike of flowers hanging down over the top of the glass from want of a support, and the glass but half-filled with water. It is a rare exception to see Hyacinths well grown in glasses in the windows of houses; and yet they can be grown there very finely indeed. R. D. H.

Plant for Wardian Case.—A worthy occupant for a Wardian case is Adiantum Capillus-veneris var. magnificum; it is one of the best Maiden-hairs in cultivation, and should have a case say 24 in. long; an hour's sun daily does it good; give plenty of air and water at the roots. I purchased a small plant in March last, and by treating it in the above manner it has grown into a fair specimen.—J. F. M., *Berners Street.*

The Tree Moss (Selaginella cæsia arborea).

The Tree Selaginella.—The accompanying illustration represents a plant belonging to the Club Mosses, or Lycopods as they are usually called. It is one of the best that can be grown on a pillar or wall in a moderately warm Fernery or greenhouse. It also succeeds well when grown in a pot or deep pan and trained on a wire or light wooden trellis. It grows rapidly in moist peaty soil, and supplies plenty of excellent material for mixing with cut flowers. For training up tall stems of Tree Ferns this Selaginella is a first-rate plant. It is easily propagated, every joint throwing out roots when kept moist or buried in soil. Its name is Selaginella cæsia arborea.

ANSWERS TO QUERIES.

3320.—**Roses for Clayey Soil.**—If the clay subsoil is near to the surface, it should be removed to the depth of 18. in. and filled in with some rotted turf and good manure, or these ingredients may be mixed with the clay together with some road scrapings and burnt ashes, the idea being to prevent an excess of moisture at the roots of the Roses, and to give them something to make roots in and feed on. On stiff, cold land the Brier will do better than the Manetti stock, so procure plants worked on the Brier for standards and dwarfs. The following sorts will be found to grow well, providing, of course, there is pure air, and the garden free from smoke, &c., viz.: Anna Alexieff, Dr. Andry, Duke of Edinburgh, General Jacqueminot, Gloire de Dijon, John Hopper, Jules Margottin, Madame Clemence Joigneaux, Madame Victor Verdier, Maréchal Vaillant, Sénateur Vaisse, Prince Camille de Rohan, Marquise de Castellane, Dupuy Jamain, and Sultan of Zanzibar. Others, of course, can be added as may be required.—WILLIAM WALTERS, *Burton-on-Trent.*

3261.—**Bulbs in China Bowl.**—The best soil would be one-third good loam, one-third leaf-mould, and one-third river sand. I would advise a better way of growing these bulbs in bowls than that usually practised. Take some strong wire and twist it together to form a net with holes the size of the bulbs; fasten it to the bowl, and then fill the latter nearly to the brim with water, placing a piece of charcoal in to purify it; then put the bulbs as you wish them arranged in the holes of the wire, so that their ends may touch the water; then cover with fresh Moss to hide the wire netting. Be sure to keep the bowl in shade the first fortnight, and change the water once a week. I myself have adopted this plan, and my Crocuses are already throwing out numerous small white roots.—BUTTERFLY.

2799.—**Keeping Rain-water Pure.**—In answer to "J. M.," I beg to state that in the mode adopted for preserving rain-water at Knockholt, no "overflow pipes in connection with house drains or sewers" are used, and therefore the evils suggested by him do not and cannot occur. Small plates of metal are fastened in the gutters, so that any leaves or other substances that may fall therein are prevented passing into the tanks. As to the quality of the water, I may state that about three years ago two samples filtered and not filtered were sent to an official analyst in London for his opinion, and his report was that both samples were absolutely pure. The water sent was taken from a tank which had been in use about five years. In having the tank underground the water in the hottest weather is delightfully cold.—S. L. C.

3270.—**Roses for Pot Culture.**—The following fifteen Roses are well suited to grow in pots, are highly scented, and may be closely pruned, viz., Alfred Colomb, Bessie Johnson, Charles Lefebvre, Duke of Edinburgh, Fisher Holmes, Jules Margottin, La France, Louis Van Houtte, Madame Victor Verdier, Marguerite de St. Amand, Marie Baumann, Pierre Notting, Princess Mary of Cambridge, Sénateur Vaisse, Xavier Olibo. These will be found a good variety in colour, and altogether desirable kinds for the purpose. Many more perhaps equally good might, of course, be added to this selection, but "Quidnunc" asks for a few. As regards the Roses with very diminutive leaves and flowers, no doubt they are the yellow and white little Banksian—

> A miniature of loveliness, all grace,
> Summed up and closed in little.

The white variety has a sweet perfume. If these are the small Roses referred to, they appear in the catalogue of Messrs. Cranston & Co., and may be obtained from that firm, or indeed from any of the leading Rose growers. The Banksians constitute a distinct class, and are good climbers when protected in winter.—WILLIAM WALTERS, *Burton-on-Trent*.

3327.—**Roses for Arches.**—Gloire de Dijon would be most suitable; in fact, it is a general favourite, being useful for almost any purpose. Madame Berard is similar in growth, but somewhat darker in the flower and foliage. For darker climbers take climbing Duke of Edinburgh, climbing Victor Verdier, climbing Charles Lefebvre, and, lastly, try Cheshunt Hybrid, which is a splendid grower, and the flowers, cherry-carmine in colour, altogether lovely and distinct. I can fully and confidently recommend this Rose for the purpose, and, with proper treatment, will be found a great acquisition. Give this Rose the warmest position of the four to be planted. Blairi is also a good and useful climbing Rose.—WILLIAM WALTERS, *Burton-on-Trent*.

3189.—**Digging up Parsnips on Strong Land.**—If your Parsnips have penetrated so deeply into the soil, it is really worth your consideration whether it would not be best to trench them out and thus trench the soil at the same time. We have never heard of any special implement for lifting Parsnips; and because the roots are usually growing so close together it would be difficult to design one that would be more effective than a stout steel fork. It is a matter well worthy the attention of tool manufacturers. Perhaps some form of implement having a couple of stout curved blades, long and pointed, might be made—these blades being forced into the ground on either side of the root, then drawn tight together by means of a screw, and then the root pulled from the ground by means of a stout lever.—A. D.

3209.—**Weeds on Gravel Walks.**—If refuse salt is properly applied in dry weather and in sufficient quantity it certainly kills weeds and moss on walks. Of course the effect is not permanent—nothing is; but I have always found an annual dressing, if the walks are well drained, sufficient. Sulphuric acid, one part to twenty of water, will also kill weeds, and when this can be obtained near the manufactory may be employed economically, but railway carriage adds much to the expense. Sulphate of copper (bluestone) is a good dressing for walks, as it does not destroy their colour in the way salt does, but it is expensive to purchase.—E. H.

3207.—**Overgrown Wall Fruit Trees.**—If I were in "E. H.'s" position I should transplant the trees from the wall to some open situation and convert them into pyramids or standards, and start again with young trees on the wall, and take care that the bottom of the wall was covered before much upward progress was permitted. If headed back to a point sufficiently low to insure the bottom of the wall being furnished, they will doubtless break, though cutting off a young tree's head is a drastic remedy.

2982.—**Bury Bugs.**—At p. 360 of GARDENING I notice two replies to a query with respect to the best cure for the bite of the Bury bug, *alias* Harvester. "E. G. H." says mercurial ointment rubbed into the places had the desired effect. No doubt; but what will be the effect of rubbing in this ointment upon his constitution in the long run? "Oxoniensis" is far more reasonable in his advice. Permit me to add mine. First, the remedy against being bitten: Soap the legs, feet, and hands with yellow soap; but this process I found very uncomfortable. In lieu, I used two parts of camphor liniment mixed with soap liniment and rubbed this over the feet, hands, and legs; but should there be a bite, there is nothing like Eau de Cologne for relief, and this should be applied also for the bites of midges, and for wasp bites chloroform. The idea is that the irritation caused by the harvester is occasioned by the bite of this little red spider. It is not so; it is caused by the germination of the eggs laid under the warm surface of the skin.—A SPORTSMAN.

3170.—**Colouring for Fruit Walls.**—The Peach cultivators of Montreuil and the Grape growers of Fontainebleau colour their walls white. Trees trained against white walls are found to be more healthy than those trained against walls more or less coloured. The following experiment is stated by M. Dubreuil to have been made in France. Two thermometers were chosen; one was placed facing a white wall, and at about 1 in. distant from its surface, the other was placed facing a black wall; in all other respects the conditions for the two thermometers were exactly similar. During daylight the thermometer in front of the white wall constantly recorded a mean temperature of 5° Fahr. higher than the thermometer in front of the black wall, and at night the difference of temperature between the two thermometers was imperceptible. Hence if we wish to obtain the maximum of light and heat the walls should be white. As to the movable frames covered with calico, would not light plank be simpler? The querist must remember that the height of his walls should depend on the forms he is going to give his trees. Upright or oblique cordons require a greater height than the palmette forms.—OMBU.

3102.—**Autumn-planted Potatoes.**—Last year was my first attempt to plant Potatoes in the autumn. Just for an experiment I planted about ½ bushel of Myatt's Prolific in the second week in October, in liberally manured well-dug ground. I planted the seed about 18 in. apart and 2 ft. from row to row, not forgetting to plant the seed 2 in. deeper than for spring planting, which is of great importance. This was my plan, and better Potatoes could not be wished for. They were free from disease and all a good size, whilst the spring-planted crop was a complete failure. I mean to plant the whole of my spare ground again this autumn to ensure a good sound crop of early Potatoes, and should advise "G. R." to adopt the same plan.—GARDENER.

3056.—**Plants under Trees.**—I find from experience that London Pride does well under trees. It grows very quickly, and always looks well.—A. J. S.

3192.—**Autumn Planted Potatoes.**—Last November I planted Ashleaf Kidneys without manure, sprinkled with soot only to keep off the worms. They came early and gave an excellent return. Garden Potatoes should not be manured; it only softens the tubers, and collects worms who bore them. Ground previously manured for Cabbages, Carrots, &c., is quite rich enough for Potatoes.—CAITHNESS.

3179.—**Removing Rose Trees, &c.**—Roses had better not be moved until the end of October, but Ferns and Lily of the Valley may be moved now without injury.—BUTTERFLY.

3201.—**Hardy Annuals.**—Sow Nemophila insignis (blue), also Nemophila alba (white), Saponaria calabrica (bright pink), Myosotis dissitiflora (blue). I should also recommend "Novice from the Cape" to try Snowdrops and Crocuses, Ixias, and other spring bulbs to be planted now.—BUTTERFLY.

3122.—**Hollow-stalked Celery.**—We have always found that hollow stalks in Celery is a peculiarity of strain and not of culture. Any good kind will not show that undesirable feature, but only coarse common sorts such as are quite unworthy of culture. One of the very best white kinds is the Incomparable Dwarf White, always very firm and solid, and Williams' Matchless is a solid taller kind. Of red Celeries the Leicester Red is a first-rate sort, very firm, solid, and crisp, and perhaps the finest of the coloured kinds is the Sulham Prize, in colour pink, and very firm and solid.—A.

3179.—**Removing Rose Trees, &c.**—Lilies of the Valley may be removed at once if desired; they should be lifted in good clumps, and be disturbed as little as possible. Rose trees should remain until the end of October before being transplanted. The wood is now maturing, and if the leaves have dropped the plants will be then in an excellent condition for removal. Ferns will also transplant better a few weeks later than now, but under any circumstances at this cool time of the year these can suffer but little if replanted now.—D.

3214.—**Window Plants.**—"Subscriber" does not say if he would like the plants to bloom in winter or spring. Presuming he means spring, I should recommend Tulips, Hyacinths, and Snowdrops, to be grown in sandy, rich soil, and covered to the depth of 1 in. with sifted coal-ashes to protect them from the frost. When in bloom, a layer of Moss at the top freshened daily with water would hide the ugly appearance of the coal-ashes and bare Tulip stalks.—BUTTERFLY.

3104.—**Mosquitos in Houses.**—Take some very dry cow manure from a pasture and let it smoulder. The smoke will soon drive away all winged insects, and will not hurt the eyes, and the smell is not at all disagreeable.—OLD SOLDIER.

3038.—**Striking Geraniums in Road Sand.**—In reply to "B. T." as to striking Geraniums in road sand, I have for years struck mine it it. I have this year struck about 5000 and only lost about fifty, of the kind known as Flower of the Day.—H. L.

3181.—**Brier Stocks.**—I can let "F. J. R." have any quantity.—H. HUTCHINS, *Hordle, Lymington, Hants.*

3184.—**Coping for Walls.**—The best is always the cheapest, and there is nothing so good as York stone. The cheap things give under the action of the weather, and the wall becomes damp and decays. Fruit trees never thrive well on a damp wall. Some of our walls here were coped with brick, but we have substituted stone.—E. H.

3108.—**Leafless Mulberry Trees.**—The unhappy condition of the Mulberry tree is doubtless due to the ungenial weather of the last two or three years. Fruit trees in many places have suffered from the same cause. A good season will put matters right, let us hope.

3334.—**Salvias in Windows.**—Will Salvia splendens flower in a window? or does it require heat?—S. G. [It will flower in the window of a warm room.]

3335.—**Pondweed in Bell-glass.**—I planted a Cape Pondweed in a large inverted bell-glass in the spring; all the leaves have come off. Would it be better to plant it in a small pot in the water?—S. G. [Yes.]

3336.—**Maiden-hair Ferns.**—*Vesuvius.*—The Fern sent is Adiantum cuneatum. It will succeed in a greenhouse temperature. Keep it rather dry during winter, and in spring cut off all the old and rusty fronds, and and when the young ones get a few inches high, pot the plants into larger pots if necessary.

3337.—**Hardy Plant Queries.**—Will three-year-old seedlings of Hyacinthus candicans blossom? [Probably.] Will Eryngium bromæfolium require protection during winter? [Yes, if in cold soil.] Will Anchusa capensis want protection during winter?—W. B. [No.]

3338.—**Paraffin or Petroleum.**—In this neighbourhood we get a little confused by the indiscriminate use of the above words. Paraffin is a solid, inodorous substance; it was formerly produced by distilling tar, but is now, I believe, found in peat. Petroleum is a mineral oil with an unpleasant odour, of which our supply originally came from the East, but latterly it has been found in such quantities in America, and is sold at such a cheap rate, that the bulk of our supply is from that continent, and is used all over this district for lighting purposes. We see paraffin recommended as an insecticide and as a heating medium, but we do not know how to use it.—S. W. K. [Paraffin is a semi-transparent white solid obtained from crude petroleum or paraffin oil. The latter substance is often popularly but erroneously called paraffin. Paraffin oil is a volatile inflammable liquid, obtained by distillation from Boghead coal, and much used for burning in lamps. As an insecticide it must be used with care, being poisonous to delicate plants. Petroleum answers all the purposes, and is cheaper.]

3339.—**Amaryllis.**—*J. W. M.*—See GARDENING for May last, in which is an illustrated article and full cultural details.

3340.—**Cuttings in Tins.**—I have three gross of empty Swiss milk tins, 3½ in. by 2½ in., and wish to utilise them. Would they do to winter cuttings in in a greenhouse if a hole was made in the bottom of each?—BOB. [We see no reason why they should not do.]

3341.—**Unfruitful Trees.**—I have a large garden, and a number of fruit trees on the wall, but for years there has been no fruit on them. What can be the cause of this? I do not think the trees are too old.—H. M. [Get the advice of some good gardener. We cannot advise you without seeing the trees.]

3342.—**Seedling Dahlias.**—*Seedling.*—You may sow Dahlia seed a good many times before you get any really good kinds. Your only way to get good Dahlias is to buy a few plants of the best kinds and propagate them every year.

3343.—**Potentillas.**—Do Potentillas require protection for the winter? I have some plants raised from seed this year that have not bloomed. Will they do so next year?—J. C. [They are perfectly hardy, and your plants will doubtless bloom next year.]

3344.—**Planting Japanese Honeysuckle.**—I have a Japanese Honeysuckle in a pot. It is two years old. Can it with safety be transplanted into the ground to grow against a wall having a north-west aspect? and if so, when is the best time to do it?—T. D. [Plant in spring. It will grow well in the position you name.]

3345.—**Clayey Soil.**—My garden is a very stiff and clayey piece of ground, and I have been advised to put

some lime on it this autumn. I intend, however, planting some Daffodils, Crocuses, and other bulbs, and wish to know whether the lime would be likely to injure them. I should also like to ask how the lime should be applied. —G. C. [Lime will be of little benefit in rendering your ground light and workable. If you can get a lot of old mortar and brick rubbish, road scrapings, or ashes, and well dig into the soil, you will do some good. The lime may, of course, be used in addition if desired.]

3346.—**Pollarding Evergreen Oaks.**—I have an evergreen Oak in good health, about 30 ft. high, circumference of trunk nearly 5 ft. at 3 ft. from the ground. As it has become too large for its position, it is desirable to cut off the branches about two-thirds of their length. Would it be safe to do this? and, if so, when is the best time?—Q. [Do it in January or February; it will be perfectly safe.]

3347.—**How to Ripen Tomatoes.**—Would it be advisable to gather several green Tomatoes that I have and place them in a south window to ripen?—B. J. C. [Yes.]

3348.—**Scale and Ants on Palms.**—*In Altum.*—The ants destroy the scale. Well brush the leaves and stems of the plants with a tooth-brush and warm soapy water; then syringe with clean tepid water. Repeat every few days till you have conquered the scale.

3349.—**Cutting down Ferns.**—*E. S.*—Do not cut them down till young fronds begin to show themselves in spring. They will not require water more than twice a week during winter unless if your greenhouse is only kept at 35° to 40°. Just keep the soil moist.

3350.—**Laurustines.**—About three weeks ago I purchased three Laurustines; they were not in pots when I got them, so I potted them into 8-in. pots, in a compost consisting of one-half turfy loam, one-fourth rotted manure, and one-fourth leaf-mould, with a good sprinkling of silver sand, potting moderately firm; the shrubs are about 1 ft. high, and about 9 in. through, of pyramidal form. During this last week the leaves of the centre main stem have turned yellow, and are beginning to fall, though they have not done flowering; it is the same on all three shrubs. Will some one kindly tell me the cause and remedy? Do they require much water?—A Learner. [The reason the plants have lost their leaves is probably because their roots were mutilated in lifting or remained out of the ground too long before potting. Water when the soil is dry, but they will not want much till the pots get filled with roots. Frequent sprinklings overhead will be of advantage.]

3351.—**Tubers on Potato Stems.**—*Ped.*—It is very common on strong-growing Potatoes, especially this season.

3352.—**Weedy Garden.**—*J. A.*—Your only course is to prevent the weeds getting established by hoeing in spring. Get a Dutch hoe, and use it vigorously two or three times a week all through the summer whether you see weeds or not, and your ground will then be less trouble to you. Burn the weeds you have cleared away, and apply the ashes to the garden.

3353.—**Grapes in Greenhouse.**—Having a small greenhouse, 20 ft. by 12 ft., for bedding-out plants, &c., could Grapes be grown in it to advantage? How many Vines ought to be planted? What would be the best and most profitable sort? How should the Vine border be made? and of what material?—Boo Peep. [Make a border 6ft. or 8 ft. wide by digging out the soil 2½ ft. or 3 ft. deep, putting in the bottom 6 in. of old bricks or clinkers; on this put some stable litter or turves (Grass side downwards), and fill up with good turfy loam from a pasture or the roadside, to which may be added a few barrowloads of horse manure, road scrapings, or inch bones. The border can be made half its width now and the other half in a year's time if more convenient. Plant any time between now and next March strong canes of Black Hamburgh Vines, which may be had from any good nursery. After planting read our calendar weekly.]

3354.—**Cutting Back Grape Vines.**—I have a Vinery in which there are a few bunches of Grapes quite hard and green. Will it hurt the Vine to cut away the branches that have done bearing fruit for the sun to get through? and will it improve the Grapes? I am going to erect a stage at the south end of the house to keep my Geraniums in through the winter. How soon may I cut away all the branches close to the Vine?—G. E. T. [Cut off the green Grapes and throw them away or make a tart of them. You may cut back to about half their length those shoots which have borne fruit, but they must not be cut in close to the old rod until every leaf has ripened and fallen.]

3355.—**Bulblets of Tulips.**—*H. P.*—Plant them out in a warm border of sandy well manured soil. Water them during spring and summer when dry, and keep them free from weeds. When they get to a flowering size plant them out where you wish them to bloom. Such bulbs are not fit for forcing.

3356.—**Clematis Jackmani.**—When is the right time to plant out this Clematis, and what is the most suitable soil?—R. M. T. [Plant now or in spring; soil, deep sandy loam.]

3357.—**New Zealand Palm.**—I have a New Zealand Palm which has grown to an unusual size for out-of doors in this country. It did not suffer from the frost or damp of last winter, and the leading shoot appears to be growing, but it has also lately thrown out three or four suckers from the stem towards the root and higher up. I am afraid whether these may not injure the tree, and shall feel obliged if you will inform me whether it will be right to remove the suckers, and how it should be done.—H. K. [Do not remove them till spring; in case the top should get killed in winter these suckers might be wanted. When you remove them tear them out by the hand if possible; if not, use a sharp knife.]

3358.—**Lawn Mowings and Vegetable Refuse as Manure.**—*W.*—They may soon be made into manure if they be laid in a large heap, so that they will ferment. If turned over occasionally and laid up in a heap again lightly, decomposition will be hastened.

3359.—**Chrysanthemum Etoile d'Or.**—*Emoorg.*—Now the plant has done flowering in the window box, pot it, and put it inside of the window or a greenhouse, and it will flower all winter. If there are any insects in the leaves dip the whole head of the plant into strong Tobacco water.

3360.—**Grapes Sporting.**—*J. Cooke.*—Send us one berry of the white and one of the black. We can hardly believe that a bunch of Black Hamburgh Grapes will sport several berries of Muscats on it.

3361.—**Planting Irises.**—When is the best time to plant Iris acuta and Iris hispanica? Also whether suited for outdoor or indoor planting?—Billy. [Plant now in a warm border of sandy soil.]

3362.—**Eschscholtzia californica.**—In a work on botany I see Eschscholtzia californica described as a perennial, is this correct? It is described as a hardy annual in seedsmen's catalogues.—J. H. [It is a true perennial; but as it may be sown and flowered in the same year and sows itself freely, it is used as an annual.]

3363.—**Moving Shrubs.**—I wish to alter the approach to my house in South Devon, and must move large Laurels, Laurustinus, &c. What is the best time to do so?—Swarg. [Now.]

3364.—**Tulips Out-of-doors.**—I have ordered for bedding for the spring three sorts of double Tulips, viz., La Candeur, Rex Rubrorum, and Yellow Roos. Now they come into bloom in succession at intervals of ten days. Can this be remedied by a corresponding variation of interval in planting?—South Devon. [We think not.]

3365.—**Wintering Plants.**—I have no greenhouse, but have good plants in pots of Coleus, Tree Carnations, Fuchsias, Roses, and Pelargoniums. These have been on stands in my garden, and in windows during summer. What is my best plan for preserving them during the winter?—N. M. [Throw the Coleuses away. Put the Fuchsias in any shed or cellar from which frost is excluded, and keep them dry. Plunge the Roses in ashes out-of-doors, and put the Pelargoniums in your windows.]

3366.—**Geraniums, Fuchsias, &c.**—I have struck several of these in pots. Should I pot them off singly? or let them remain until the spring? I have no greenhouse to keep them in. Is it too late to take cuttings of Verbenas and Petunias?—A. M. K. [Let them remain till spring. It is doubtful whether Verbenas and Petunias will strike now unless you can put them in heat. We would lift a few of the old plants and pot them.

3367.—**Salvias not Flowering.**—Why is it that my Salvias planted out-of-doors are all gone to leaf, very large leaves, and no flowers, whilst one blue one kept in the greenhouse in a pot run up very lanky and ugly, but flowered well?—Finetta. [Most of the Salvias flower in autumn and spring. The blue one flowers in summer. Lift the plants with good balls of earth and pot them, and place them in the greenhouse; they will then flower. They should have been kept pinched in during summer to render them bushy, and should have been potted in September.]

3368.—**White Passion-flower.**—A white Passion-flower, planted (in the ground) in the greenhouse, besides making an enormous growth, has thrown up a great many suckers. Will they make as good plants as seedlings would do?—Finetta. [Yes.]

3369.—**Worms in Soil.**—I have a quantity of soil in which there are a number of slugs, maggots, and worms. What is the most simple way of getting rid of these pests?—S. G. W. [Mix some lime and soot with it, and turn it over frequently.]

3370.—**Horseradish in Drain Pipes.**—At page 353, does your correspondent pack the drain tiles close together, ends up, or apart? How long before he gets a fine clean stem this way?—C. [Close together. They are filled with soil, of course, and the ground in which they stand is rich. It takes a year to get good clean heads.]

3371.—**Fuchsia Leaves Curling.**—*Tom W.*—Keep the plant dry and all the leaves will fall off. In spring prune back the shoots to firm wood and it will flower well next summer.

3372.—**Pears Cracking.**—*W. J. T.*—The best remedy is to cut the tree well in, and graft on it another kind of Pear.

3373.—**Potting Bulbs.**—*A Learner.*—Hyacinths, Crocus, Tulips, Narcissi, and Daffodils may all be potted at the same time, but they may not all flower at one time, which is a great advantage, as the display is kept up for a longer period.

3374.—**Cutting Hedges.**—I have a Privet hedge which has grown far too high and thick. When is the proper time to cut the wood well back?—V. [April or August.]

3375.—**Evergreens on Palings.**—What would be the quickest-growing and most suitable evergreen to plant as a screen against some iron palings about 4 ft. 6 in. in height?—F. E. [Any of the large-leaved Ivies.]

3376.—**Vallota purpurea.**—Is it essential that these bulbs should be only half buried? I have some in pots that have been potted a year, but have not flowered. Would it be better to repot them shallower, or to let them stay buried up to the crown?—Lily Grower. [If they are too deep remove a little of the surface soil with a pointed stick. Keep them rather dry through the winter and spring; if you can give them a warm light place they will probably flower freely.]

3377.—**Planting Clematis and Ivy.**—*A. J. B.*—If the weather is open you can move Clematis Jackmani and Ivy between present time and end of next March.

3378.—**Crocuses.**—I turned out some Crocuses the other day that had been left out-of-doors in pots since flowering, and found in the shell of the old bulb three or four small bulbs about the size of Peas. Will they flower next year?—A. J. B. [Plant them out in good soil and let them alone; they will probably flower next year.]

3379.—**Laying Down Grass.**—Is it too late this year to do this? [No; if the weather is open.]

3380.—**Vines in Greenhouse.**—I am going to have a greenhouse made, but the aspect must be N.E. Would Grapes ripen there without the assistance of heat? How would it suit flowers?—A. J. B. [Grapes would be a failure without heat in such an aspect. Ferns, Camellias, Azaleas, &c., would do in it, but not flowering plants in general.]

Names of Plants.—*R. C. S.*—Scabiosa atro-purpurea. ——*Sener.*—Chrysanthemum Burridgeanum.——*C.*—Anemone japonica.——*E. G.*—Cannot name without flowers.——*G. M. O.*—Briza maxima.——*F. W.*—Aster hyssopifolia.——*A. H.*—1, Chrysanthemum segetum: 2, Godetia Whitneyi; 3, Tagetes patula.——*J. B.*—Tradescantia (species).——*T. F.*—Convolvulus Soldanella. ——*Ped.*—1, Lophanthus rugosus; 2, Melissa officinalis; 3, Monarda fistulosa; 4, Antennaria margaritacea.——*S. S.*—Clematis tubulosa.——*Beta.*—1, Portugal Laurel (Cerasus lusitanicus; 2, Acacia of some kind; 3, Birch of some kind.

QUERIES.

3381.—**Flowering Shrubs and Rock Plants.**—I shall be obliged if any one will give me the names of some hardy flowering shrubs, such as American Currant or Guelder Rose; also the names of flowering plants and Mosses for rockwork—perennial and hardy.—Olive.

3382.—**Aristolochia.**—Can any one tell me how to treat this creeper? It has been tried in a west and east aspect and has made no start. The soil is sandy and light.—Bournemouth.

3383.—**Early Tomatoes.**—I am desirous of growing early Tomatoes. Will some grower of them tell me the earliest and best bearing varieties? also whether I should be able to produce the fruit in a heated Vinery by January or February? if so, how?—G. S.

3384.—**Indian Pinks.**—I have some seedlings of Indian Pinks now nicely rooted in small border running under brick wall facing south. Will they stand the winter there? Having never before grown them, will they do to plant around outer edge of a bed of Carnations, Picotees, and Pinks?—Henry K. N.

3385.—**Planting Vegetable Garden.**—I am now trenching back a piece of land to make a garden, and should be glad if any one could give me a few hints as to what vegetables, &c., should be planted in the autumn.—R. M. T.

3386.—**Flowers for Winter Blooming.**—Will some one advise me what seeds to sow for blooming in the greenhouse in the winter? also the treatment the plants will require?—A Subscriber.

3387.—**Plants for Window Box.**—I have a box outside my window which faces south-west in a smoky district near Bolton, in Lancashire; what can I put in now that will look pretty up to Christmas time? and would it be too late to put bulbs in then? I should also like a few suggestions as to what to put in it all the year round so as to keep it bright and pretty.—Monte-jumbo.

3388.—**Carpet Plants.**—Will some one please give me the names of good carpet bedding plants and colours for a bed with a basket, 4 ft. 6 in. square, in the centre, to be surrounded by eight distinct coloured rings for next summer?—A Learner.

3389.—**Crayfish and Gold Fish.**—I have some gold fish in a globe, and think some crayfish would look pretty with them. Can any one inform me if the crayfish would destroy the gold fish?—M. J. B.

3390.—**Bush Gooseberry and Currant Trees.**—I have 200 of the above in a garden I have lately taken, some of them in almost a wild state. How shall I treat them?—Quiver Dunstable.

3391.—**Preserving Rose Hips.**—How can I preserve these for winter decoration? I have tried putting them in strong pickle, but they have lost their colour. —H. M.

3392.—**Fuel for Greenhouse Fire.**—As winter is drawing nigh and it is about time to think of getting in fuel for the greenhouse fire, will some one inform me whether anthracite coal would not be better and more economical than gas coke, which costs 18s. a chaldron. We cannot get any coke cheaper than the price above quoted, and a large proportion of heating power must have been extracted in the process of gas making. My house is heated by an ordinary horizontal brick flue, reaching along two sides of the house in a horse-shoe shape.—Coal *v.* Coke.

3393.—**Virginia Creeper against Wire.**—Will one of your readers kindly tell me whether it be possible for Virginia Creeper or Ivy to prosper if planted against a wire partition? I planted a beautifully rooted Creeper against a wire partition not long ago, but it does not get on at all. I wish to have something green and fast growing. Is there a hardy plant to be got which will grow well trained to a wire trellis?—Jeearess.

3394.—**Gum Cistus from Seed.**—Will any one tell me how long Gum Cistus raised from seed take to make good plants? In buying one, how should I mention "the one with a purple spot on each petal," as I have been disappointed in having one with the petals all white?—Finetta.

3395.—**Scale on Orange Trees.**—How can I get rid of this? A week after an ordinary washing this pest seems as thick as ever.—W. H. Jones.

3396.—**Culture of Hollyhocks.**—Allow me to ask some successful grower of the Hollyhock for information as to the time and mode of propagating it by cuttings, its culture, and how to remedy the disease; and also, I should like the names of a collection that would give credit to the purchaser.—Walsal.

3397.—**The Polyanthus.**—May I ask the names of a few of the most choice varieties of Polyanthus, time of propagation, and what protection they require?—Walsal.

3398.—**Cardinal Flower.**—Will some reader who has been successful with Lobelia cardinalis tell me how it should be managed during the winter so as to get a fine bud of it in summer? I have a great many pots of plants raised from seed; they are rather tall plants.—P. M. F.

3399.—**Cerastium Edgings.**—I never can succeed in getting my edgings of this satisfactory; they are always rusty looking at the bottom. I should be much obliged for cultural instructions respecting its growth and management.—James Logan.

3400.—**Rose of Sharon under Trees.**—Will any one tell me if Rose of Sharon will grow under trees?—A. H.

3401.—**Gnat Bites.**—Will any one kindly tell me a cure for the painful bites of the gnats and midges which infest the garden?—Butterfly.

3402.—**Pruning Gloire de Bordeaux Rose.**—I have a Rose of this sort planted against a south wall for two years, but, as yet, it has not shown a flower; it has grown very strong, and has shoots about 7 ft. long. Will any one please say how it should be pruned?—Loch Lomond.

3403.—**Seaweeds as Ornaments.**—How can I preserve seaweed, of which I have just brought home a pleasing variety? should be glad to know how to use it for a permanent ornament.—S. M.

3404.—**Daisies on Lawn.**—I should be glad if any

of my fellow readers can inform me of a simple method of eradicating Daisies from a lawn.—H. R. Keates.

3405.—**Pruning Gloire de Dijon Rose.**—In a number of Gardening in August Gloire de Dijon is spoken of as requiring special pruning. Can the writer of the article say what it consists of? I can grow plenty of wood, but few flowers.—T. C.

3406.—**Climbers for Dwelling House.**—I have a large newly-built house two miles from the sea in the south-west of Scotland, the walls of which I am anxious to cover as soon as possible with hardy creepers. What will be the best sorts for the different aspects, and when should they be planted? What is the quickest growing Ivy? and are there any other evergreen creepers?—In Altum.

3407.—**Trees for Screens.**—I wish to plant a narrow belt of trees as a screen in a situation exposed to strong sea-breezes; what would be the best sorts, and time of planting? also the best sorts of ornamental trees and shrubs to plant in the pleasure grounds with same exposure.—In Altum.

3408.—**Flowers and Shrubs in Greenhouse Killed by Tar Varnish.** In consequence of the hot-water pipes in large hothouse having been painted over with tar varnish, a large number of Ferns and valuable plants have died off, and great mischief is still being produced. Are there any means of killing the tar varnish or painting it over with any kind of paint to destroy the fatal effect?—Hyacinth.

3409.—**Oleander not Flowering.**—My Oleander, some three or four years old, will not thrive or blossom. It is in good loamy soil, has just been repotted, and is in a cool greenhouse plentifully watered. The leaves, as soon as they appear, turn yellow, scales come on the backs of them, and the new shoots are curling up and withering. What can be the cause?—Orient.

3410.—**Fungus on a Lawn.**—My lawn is infested with a small black fungus that creeps close to the ground and destroys the Grass, besides being unsightly. A Spruce Fir tree grows near, some of the boughs overhanging the spot, and the soil is sandy. What can I do to remove the fungus?—Orient.

3411.—**Height of Geraniums.**—With a view to planning out my beds for next year, I should be obliged for the relative heights of the following Geraniums:—Lucius, Master Christine, Wonderful, and Madame Vaucher.—V.

3412.—**Poultry Manure.**—Is poultry manure available for using as a heap whereon to grow Vegetable Marrows? I should be very glad of any of your readers' experiences in the matter.—V.

3413.—**Briza maxima.**—This Grass has been introduced this year with very good effect in my window-boxes. Can any one suggest any other hardy annual Grass which can be so grown with advantage?—V.

3414.—**How to Grow an Orange Tree.**—Can any reader give me any information how to grow an Orange tree in a window? It is about 6 in. high, and in a 6-in. pot. What kind of soil is best?—A Learner.

HOME PETS.

Keeping Doves.—I became possessed of a pair of ringdoves three or four years ago, and, pitying the condition they were in, from confinement in a cage much too small, I constructed one for them in a rough way, from unplaned wood and wire netting, about 4 ft. long by 2 ft. wide, and 3 ft. 6 in. high, perches wide enough apart to allow the birds free use of their wings. The cage is on a stand about 30 in. high, and is made with a high gabled roof to the perches in which they retire to roost. Such a cage with wirework only in the front affords sufficient protection in any but the severest weather, when I sometimes put them into a smaller one to bring indoors for the night. As to food, finding Hemp and Canary seeds rather expensive, I determined to try Barley; this they would not take to till pretty severely pressed by hunger, but they will now keep in perfect health and thrive upon it. One day, by way of experiment, I put some Indian Corn into the cage. To my surprise they gorged themselves most voraciously with it, as if it had been the greatest delicacy that could be offered. I now keep them almost entirely upon it. A shallow vessel of water 8 in. or 9 in. wide for them to wash in every few days is a great treat, and the door of the cage should be made wide enough to admit this. I find a sprinkling of garden earth about ½ in. deep on the bottom and changed once a week, keeps the cage very clean and sweet.—A. C.

Disease in Pigeons.—Many of our our pigeons are suffering from a disease in their feet and skin by being covered with warts. I should be glad to know of a remedy.—S. G.

Canaries.—Will some kind reader answer the following questions about canaries: 1—Does bread injure canaries? 2—Will it do for a cock parent and this year's hen to breed together next spring? 3—Who is the publisher of a sixpenny book about canary breeding?—A Subscriber.

Canaries with Asthma.—I have tried the Canaradyne for birds with this complaint, but have not found it do any good. I had a pair of lizard canaries, both suffering terribly. I kept them in a warm room, but the hen died. At last by chance I saw in a paper that canaries were more subjected to pulmonary complaints than any other birds, and require to be kept in a bracing air. I therefore placed the survivor in a cool room, and now it is quite well. I only give canary seed, brown millet, and pure water, no green food. The bird fancier told me to keep them warm.—A Lover of Birds.

POULTRY.

ON FOWL KEEPING IN SMALL SPACES.

Any one keeping fowls without an extensive Grass run cannot expect to make the undertaking profitable. With care and judgment it may be made to cover expenses, but the probability is every egg will cost threepence rather than a penny. I am continually asked, "Do your fowls pay?" and I am compelled to answer, "If by paying you mean do I make money by them, certainly not." But I get a great deal of interest and amusement out of them, besides having fresh eggs.

Cleanliness, Size of House, &c.—The chief points necessary to success in fowl keeping are perfect cleanliness, suitable food and warmth, and judicious selection and management of stock; and I place cleanliness first, because, unfortunately, it is the thing most often neglected, and fowl-keeping then becomes a nuisance to neighbours, and the birds will not thrive. Some people think any sort of covered shed will do for a fowl house, no matter how small, draughty, or ill-ventilated it is. Of course, the first consideration is that the roof should be perfectly water-tight, and the walls free from chinks that would let in draughts. To ensure ventilation, one or two holes should be cut in the wall close under the roof, and the opening covered with finely perforated zinc. As to dimensions, Mr. Wright, who is the great authority on poultry, says, "For a cock and five hens a house 5 ft. or 6 ft. square is sufficient." I should prefer at least twice that size myself for the same number of birds. The sleeping-house must be swept out every morning without fail. It is only the work of a few minutes if so done; whereas, if left till there is an accumulation of filth, it is a task that no one likes to undertake, besides being a fruitful source of fleas and other vermin in the birds. The floor of the sleeping-house should be of asphalte or cement, brick or boards, must be by all means avoided. After sweeping, a little dry earth should be thrown down under the roosting perch. Sand is nicer and cleaner looking, but is too expensive for general use; the earth answers every purpose, and prevents all disagreeable smells.

Fowls' Manure.—One caution must be given about the fowls' manure. It will not do to use for plants without great care. It is, in fact, the strongest guano, and unless exposed to the air for months, and then much diluted, it would kill whatever was treated with it.

Protection from Vermin and Disease.—Once every six months the walls of the house and inside of the nests should be lime-whited, and if there is the least suspicion of vermin in the birds, before lime-whiting go carefully over the house with paraffin or carbolic acid, applying it with a small brush wherever there is a crack or harbour for the insects.

Fowls' Runs.—The run, which should be as extensive as it is possible to allow, should have a south or south-east aspect, and it is essential that some portion of it should be covered over to afford shelter to the birds in wet weather. If possible have a light, movable division or door that will divide the run into two parts. A frame of wood covered with zinc wire netting, or even string netting, will answer very well. It is often necessary to separate some fowls from the others in case of sickness or or quarrelling, and fowls get very tired of being shut up in one place, and even such a slight change as shifting them from one part of the run to another is beneficial. The floor of the run must be thoroughly drained. It should be dug out to the depth of 1 ft., and have a layer of old brick rubbish and old mortar; then fill up with earth and sand, and beat as hard as possible. This should be swept down once a week at least, oftener in hot weather; and after sweeping cover with dry road sand.

Dust Bath.—Under the covered part place the fowls' dust bath. The simplest way is merely to throw a heap of dry earth or sand in a corner, renewing it frequently. Dry sifted ash from a greenhouse furnace answers very well in the absence of sand, but if allowed to get wet and trodden into the run it smells very unpleasant.

Poultry as a Profitable Investment.—Being greatly interested in all that concerns poultry keeping, I give your readers my experience of it. I keep Toulouse geese, Rouen ducks, dark Brahma fowls, and several kinds of pigeons. I have had geese at eight weeks old weighing 12 lb. each at a cost of 2d. per week, ducklings I get ready to kill in twelve weeks at a cost of 1½d. per week, and Brahma chicks eighteen weeks at 1d. per week. Pigeons are unprofitable with me, excepting fancy birds, as every pair costs me 1s. 8d. before they are ready for market. Brahmas as layers with me are excellent. I have had them lay twenty-eight days without missing a single day. I have heard and read a good deal about poultry farming, more against than in favour of it. My opinion, after ten years' experience of poultry keeping, is most certainly in favour of it. I have myself reared 200 ducks in a season, beside chickens and geese, enclosed in a piece of ground about half a rood, and had them taken from my yard as soon as they were ready to kill at 3s. each. I have not reckoned the cost of keep of stock birds in ducks and geese during the year, as mine have generally won as many prizes as have paid for their keep.—North Yorkshire.

AQUARIA.

Fish Dying in Tank.—I have a small brick tank made in a rockery in a conservatory, and lined with Portland cement. There is a small fountain in it which I often keep playing. The rockery, on which many greenhouse Ferns are flourishing, faces south and east, the later morning rays being sheltered by the west wall of the house, and during summer the glass has been shaded nicely by green colour and size. The sun does not shine brightly on the water, but it gets light, though the rockery slightly overhangs it. I had in it five gold fish, two golden tench, twelve minnows, a few mussels, and water snails, but all the fish have died since except two gold fish. There is nothing wrong with the cement, for it was well scalded and cleaned several times before the fish were put in. The bottom has about 2 in. of sea beach, well washed, laid over it, and I have three times got water weeds and planted them, but all have died. I had the tank finished in February or March, but my fish died, and also the weeds. The fish generally got white fungus over their bodies, and some lost their tails. Can any one advise me?—R. A. P.

Plants for Aquarium.—"Stickleback" wants to know if zinc proves injurious to water plants. By this I presume his tank is made of that metal. My own aquarium, as described in a previous number, is made entirely of zinc, and my water plants have grown most luxuriantly, their roots having been buried in a small quantity of river mud, which was placed in one corner and covered with a few shells and stones. If "Stickleback" requires plants for an 8-in. aquarium that will grow very little above the water, let him try the Water Soldier (Stratiotes aloides), which grows to perfection in an aquarium, as it delights in still water. This is, indeed, a very beautiful aquatic plant, as its leaves droop over and form a shelter for the fish. Also try the Frogbit and young roots of Potamogeton natans, a plant which is common enough in our ponds. It is known by its broad, green-pointed leaves floating on the surface of the water, and would be taken for a small kind of Water Lily, but for the difference in blossom.—Newt.

Cement for Aquarium.—Mix white and red lead together with stiff gold size to the consistency of putty; a little lampblack will darken it if desired. This cement sets quickly, and becomes as hard as iron in a few days; and is useful for many purposes.—J. C. Kershaw, *Chester*.

Gold Fish.—In reply to "Una," my advice is to try a fountain that could be kept going all day, if not at night. My fish were exactly the same as his at one time, but on introducing a fountain the difference seemed to be almost momentary, and they are never at the water's surface now, unless, however, my fountain should cease for a few days. "Una" might find it difficult to erect one in a glass globe that would require little or no attention, but even that can be accomplished. Roberts' food for fish can be obtained of Mr. G. J. Roberts, 132, Pentonville Road. Fish are desperately fond of it, but it should not be given more than three times a week.—Newt.

Management of Indoor Aquarium.—Will any correspondent give me a few hints on the management of an indoor aquarium? What is the proper food for the fishes? What does it indicate when the fish come to the top of the water and seem to pant? How often the water should be changed? Whether the green accumulation on the stones at the bottom should be removed, &c.?—A. B. C.

TREES AND FLOWERS IN AUTUMN.

Now what hath entered my loved woods,
And touched their green with sudden change?
What is this last of Nature's moods
That makes the roadside look so strange?

*

Who blanched my Thistle's blushing face,
And gave the winds her silver hair?
Set Golden Rod within her place,
And scattered Asters everywhere?

*

Who splashed with red the Sumach hedge—
The Sassafras with purple stain;
Gave Ivy leaves a ruby edge
And painted all their stems again?

*

Lo! the change reaches high and wide,
Hath toned the sky to softer blue;
Hath crept along the river-side,
And trod the valleys through and through.

*

Discoloured every Hazel copse,
And stricken all the pasture lands;
Flung veils across the mountain-tops,
And bound their feet with yellow bands.

*

Is, then, October come so soon?
Full time doth summer ne'er abide?
While yet it seems but summer's noon,
We're floating down the autumn tide.

AUTUMNAL FLOWERS AND LEAVES.

TREES AND SHRUBS IN AUTUMN.

This has been an exceptional season for displaying the glorious tints of autumn leaves, and where trees were planted with a view to autumnal effect the reward this year will be ample. The following notes by Mr. Berry, of Longleat, will, we hope, be instructive as a guide to anticipating planters.

The Norway Maple (Acer platanoides) was the first to colour, and quite out-shone all its compeers with brilliant and gorgeous-tinted leaves; the colours varied from yellow to glowing fiery-red. The contrast and effect, particularly in the noble and spacious avenue leading from the chief lodge to the mansion, which is planted in double rows alternately with Lime, Elm, and Norway Maple, was a grand sight to behold; the latter at their best stage of colouring seemed to be so many shining lights amongst their more sober-coloured neighbours. The park was literally lit up with them; each tree, so to speak, was like a tree on fire. Of other Maples that coloured before the fall of the leaf, the most noteworthy were Acer colchicum rubrum and Acer Schwedleeri, both dying off pure yellow; the young leaves on the latter during summer are claret coloured and highly ornamental. Last year being wet, the Tulip tree did not appear in its usual deep yellow-shining suit, but this year it is brilliant. The Liquidambar is amongst the richest of autumnal-tinted trees; it is usually beautifully coloured before dropping its leaves, often varying from purple to vermilion and other fiery colours. I am pleased to be able to note that the comparatively new purple Birch may be classed amongst and in the first rank of gay autumn-coloured trees. A fine specimen growing here is just now clad in foliage varying from bright chestnut to vermilion. This Birch is a very free and fast grower; indeed, my experience of it is that it seems to over-grow its strength. The stem and branches become so long and slender that it can rarely withstand rough winds without suffering breakages. I intend in future, when planting this particular tree, to be sparing with rich soil, so as to check its over-luxuriant growth. It is a grand acquisition as a landscape tree, and can hardly be too extensively grown. Whilst speaking of Birches, allow me to draw the attention of ornamental planters and nurserymen to the upright Birch (Betula fastigiata); it deserves to be better known than it now is, for I think it is destined to become a most effective and useful tree, especially adapted for town and suburban parks and gardens, as well as for general landscape planting. It is not so stiff in outline as the Lombardy Poplar, being more light and airy in habit, with a strictly fastigiate growth. I believe it is of Continental origin, and, as yet, only sparsely distributed in this country. The specimens I have of it were imported from France some few years back; they are now about 12 ft. high, and I must say that I am much impressed with their distinct and characteristic appearance.

The stately old Elms in the park are just now fine pictures in burnished golden clothing. The Beech has nearly thrown off its annual russet-brown mantle, and the deciduous Cypress (Taxodium distichum), a shade deeper and brighter than the Beech, stands out very prominently, and is still a mass of bright warm brown-umber coloured foliage; this tree forms a striking and pleasing contrast to all other Conifers on account of its feathery and elegant foliage. There is a weeping variety of it, but it is inferior to the type in every feature. The Wild Cherry (Cerasus vulgaris) must not be omitted from the list of bright, fiery-tinted trees in autumn, some specimens of it here being very conspicuous and beautiful in the landscape; it is a grand pictorial tree for parks and pleasure grounds; yet how scarce it is, generally, in parks, and how seldom planted in situations which are so well suited for such a charming tree to occupy prominent sites for displaying its sheet of white blossoms in spring and brilliant autumn foliage to advantage. Amalanchier floribunda and ovalis, as usual, coloured scarlet and crimson; and Aronia grandifolia was also richly tinted. Some of the American Thorns were coloured with various gay tints, as is usually the case in ordinary seasons.

I will now offer a few remarks on autumn-tinted shrubs, amongst which the old-fashioned Sumach (Rhus typhina) carries off the palm for intense colours with its graceful and brilliant scarlet foliage. Rhus Osbecki is not much inferior, the colours being more varied. Rhus Cotinus is not deficient as regards its violet and red tints. Euonymus europæus shed its foliage in bright magenta colours, and laden with seed, the cases or capsules of which are hardly less attractive than the rich autumn leaves. The great advantage of this shrub over all others is that after the birds have carried off the seed the pretty seed-cases still hang gracefully on the bushes, and will remain ornamental and attractive during the greater part of the winter months. This peculiarity renders Euonymus europæus invaluable as an ornamental winter shrub. Euonymus latifolius was slightly coloured; its leaves and seed-cases are much larger than in the common variety, but the latter very soon become discoloured and drop off; it is inferior in every way to the common variety. The common Dog-wood (Cornus sanguinea) is worthy of notice as a well coloured shrub; it dies off a deep blood-red colour. Its glossy red bark, too, which is best seen to advantage after the leaves have fallen, is an attractive feature of this shrub. Clethra alnifolia is a late-blooming shrub that sheds its leaves golden-yellow. Virgilia lutea dies a deep yellow. Viburnum Opulus (the Guelder Rose) was beautifully tinted; so was V. plicatum. The Viburnum family are all good ornamental shrubs, and valuable for contrast and effect in pleasure grounds. The old variety, V. sterilis, snowball-flowered, is always a pleasing object, especially so when backed up by dark evergreens, its snowy-white, snowball-like flowers showing up prominently. V. macrocephalum is a variety with immense flower-heads. The glossy leaves of Ribes aureum exhibit a variety of lovely tints. Cotoneaster Simmondsi is just beginning to show up its bright red colours; when well coloured and laden with yellow fruit it forms a striking object in the ornamental woods here. The birds do not molest the seed until pressed by hunger during hard weather, which is a great recommendation amongst berry-bearing shrubs. The same remarks apply to C. acuminata and C. frigida; the fruit on them also may often be seen still hanging after most other fruit-bearing shrubs have been cleared by birds; indeed, save these berry-bearing shrubs just mentioned, there are now hardly any worth growing for the beauty of the fruit alone. Since the Gun License Act came into force small birds have become so numerous that as soon as the fruit is ripe it is swept off in a few days. Ten years ago I could cut any quantity of branches of the Mountain Ash covered with its beautiful fruit at Easter-tide for church decoration purposes, but now not a berry can be found a fortnight after being ripe. The Cotoneasters named are the only exceptions that have come under my notice. Lastly, the common Azalea must not be forgotten as a choice autumn-tinted shrub. It has been, and still is, throughout the ornamental woods everywhere conspicuous, displaying its bright-tinted foliage of almost every hue from yellow to purple and red.

Making Lawns.—In reply to several queries in Gardening on this subject, if there is sufficient depth of soil, trench, burying the surface soil with the weeds to the depth of 18 in. any time during winter or early spring when the ground is sufficiently dry to work pleasantly. The advantages of trenching are, that existing weeds are got rid of, and the fresh soil, besides being free from weeds, is more likely to send up a vigorous plant. The soil should be kept as light as possible after trenching, to allow air and water to pass freely through it, which will sweeten and assist in pulverising it. During the trenching the level should be kept as accurately as possible, and if a very exact level is required, it should be done shortly before seed time with the spirit-level, straight-edge, and pegs; but we generally find that a skilful man can do this with his eye. The ground should then be let lie until owing time, which will be about March or April, according to the weather, remembering that dry weather should be chosen for the operation. It should then be forked lightly over and raked until a fine tilth is produced, which is most necessary for Grass seeds. Now tread the ground or roll it until it feels comfortably solid under the foot, which is a very necessary part of the preparations. Scratch the ground with a rake until a little fine soil is produced wherein to sow the seed. If artificial manure is necessary it should be sown after the consolidating of the seed bed at the rate of 5 cwt. of lawn manure to the imperial acre (4840 square yards) raked into the surface-soil, and the seed sown immediately after. A calm day is very necessary for sowing, the seed being easily blown about by a slight puff of wind. Two garden lines should be stretched about 4 ft. or 5 ft. apart to sow between, and the ground should be sown at least twice, which will materially assist the even distribution of the seed. When a breadth has been sown it should be lightly raked and covered to the depth of 1 in. or 2 in. with a mixture of well-decomposed stable manure and leaf-mould in the proportion of about one to two, which should be nicely levelled and not walked upon until the Grass is all well through, when it should be lightly rolled. The ordinary quantity of seed is 4 bushels, but where a lawn is required in the space of two or three months double the quantity is requisite. Although April has been mentioned as the time to sow, it is perfectly safe to sow Grass seeds any time up to the end of September, providing the weather is sufficiently damp. The after management consists in mowing with a scythe as soon as the Grass is high enough, and this should be continued as required, using the scythe for the first three or four cuttings, and after each cutting, rolling well with a light roller. The machine may then be used if desired, but set it as high as possible for the first half-dozen cuttings. Mowing, watering, rolling, and an occasional edging are all that will be required for

some time. When the lawn is well put down it gives greater satisfaction in every way, being easier to attend to, fresher in appearance, pleasanter to walk upon, and lasts longer in good condition than one that is put down in a slovenly manner, with the view to getting through the work as quickly and cheaply as possible.—J. Carter.

TOWN GARDENING.

HINDRANCES TO PLANT GROWTH.

Gardening in towns differs from gardening in the country, inasmuch as, besides the usual labour of raising your plants and keeping them in health, there are three great enemies to plant growth which have to be combated with which the country gardener is but little troubled.

1. **Impure and Poisonous Air.**—This is the greatest enemy by far that our plants have to contend with, as it is more subtle and difficult to deal with than the others. It must be borne in mind that this impurity is divided into two classes—first, actual mechanical impurity, consisting of the soot, smoke, dust, and dirt with which in various forms the air of our cities is loaded. This is much more easily dealt with than the second kind, for by covering, as far as possible, our plants with glass, and thereby preventing the continual deposit upon their leaves, &c., of these injurious particles which would otherwise take place, and which choke up the pores and so suffocates, and in time kills the poor plants; also by constant washing, syringing, &c., the plants and their leaves, especially when the former precaution cannot be taken (and even when it can, as an additional advantage), we can to a great extent moderate this evil. But the second kind of impurity, the chemical, is much more difficult to deal with. The only condition under which this evil may be at all successfully dealt with is in the artificial atmosphere of a conservatory or greenhouse, and the larger the internal area and contents of such a structure, and the greater the extent of healthy vegetable growth and foliage contained within it, also the more perfectly, consistent with the health of its inmates, the external atmosphere can be excluded, the greater will be the consequent advantage. We have found some benefit from the use of Condy's Disinfecting Fluid in the town greenhouse.

2. **Absence of Light.**—Another great drawback to the culture of plants in towns is the gloom, comparative absence of sunshine, and general want of that clear wholesome light which is necessary to the healthy growth of all kinds of plants, and which prevails to so great an extent in large cities, especially in the winter season. This applies also to the last-mentioned evil, viz., the impurity of the air, which is much greater in the winter than the summer season, from the greater number of fires employed for household purposes, &c.; so that on these two accounts common sense tells us that summer is the season for the town gardener, and in practice this is found to be so; his efforts to obtain a winter or even early spring display will meet with but a poor reward, as a rule. All that we can do is to keep all glass, &c., as clean as possible, especially during the dark days, and to take care that our plants get every ray of light that can be had. One great hindrance is that town gardens are often more or less surrounded by high buildings, and in such a case every precaution will fail to prevent the plants being drawn up, and to some extent weak and lanky in appearance. Hence it is advisable, wherever it is possible to do so, to have our conservatory or greenhouse constructed upon the roof of the house, or on as elevated a position as can be had; even outdoor borders may be arranged advantageously on such a space, for plants like a wide uninterrupted view, and light and air all round them, and this is sometimes the only position where they can obtain it.

3. **Unwholesome Soil.**—The sour, soot-permeated, unwholesome, and often altogether worthless soil that is usually found in town gardens is another drawback to the successful culture of plants, but is by far the least formidable obstacle to our success, for though we cannot bring pure air or light from more favoured localities for our pets, yet we can bring them pure wholesome soil; and our friend common sense tells us that in order to counteract as far as possible other unfavourable conditions, we must give our plants the very best of soil and other necessaries that we can. This will be fully treated on hereafter in a chapter on soil.

Cleanliness.—One point must be steadfastly adhered to, viz., cleanliness, no dirt, no disorder anywhere, but clean pots, as clean as water and scrubbing-brush can make them, both inside and out; clean crocks, clean soil (this is no anomaly), and in your greenhouse or window not only clean plants and foliage, but clean shelves and glass and floors; in fact, everything as clean as it can be. Plants hate dirt; it is poison to them; and where a man can live and be in health for fifty years or more an Oak tree may die in a year or two, and all from dirt in one shape or other. Take, for instance, a potful of rooted cuttings where a nice clean pot has been used, clean crocks carefully put in, over that a little Moss, and filled up with nice sweet soil that will scarcely dirt one's fingers. When reversed and turned out on the hand how nice it looks! how the clean white roots coil neatly and strongly among the soil and crocks! and how healthy the leaves above appear! above all, how they grow! Now take one where an unwashed pot has been used, a lot of messy soil crammed in, and the cuttings poked in anyhow, as some people do, and what is the result? Why, failure and disappointment, of course.

There is one other great difference between the air of town and country, viz., that in the former, from obvious causes, the air is so much drier than outside. It is scarcely necessary to enter into an explanation of this difference here. It arises from several causes, the chief of which is, that whereas in the country the surface of the ground is almost entirely covered with vegetation—trees, Grass, &c.—all of which act as reservoirs, as it were, of moisture, as well as distributors, by storing up within their tissues, &c., to a great extent, the rain that falls upon them, and afterwards continually giving off this, as well as what they draw from the natural and constant moisture stored up in the soil by gentle and steady evaporation from their leaves and blades. Yet in a town there is nothing of the kind; paving-stones, bricks, and tiles do not store up any appreciable amount of moisture, and consequently cannot give off any, or at least only a little just after rain. This circumstance leads us to the conclusion that not only may syringing, watering, &c., especially in dry weather, be practised advantageously to a far greater extent than would be advisable in the country, but that this, with other dwarfing influences, renders suitable a much richer soil than is needed where these influences do not exist.

Manure.—Speaking of manure, it is astonishing how much this very important point in the production of good crops of either flowers or vegetables is neglected, especially by amateur gardeners. People are beginning to find out now how very important heavy manuring and deep digging are in the growing of vegetables, but many do not seem to think it necessary to give their flower-beds any nourishment. This is a great mistake; flowers want manure just as much as vegetables do, though it should be of a more delicate, or rather less coarse, description, and it must not be used in such large quantities. Take Geraniums, for instance; the old style used to be poor soil and as little water as possible; now we give them rich soil, though not too much pot room, and plenty of water and liquid manure, and look at the glorious heads of bloom obtained by this method as compared with the old. Therefore, give your flower-beds a good dressing of either leaf-mould—which is much milder and more suitable as a rule for flowering plants than rank manure; or this last, either alone or in addition to the decayed leaves, if very old and thoroughly decayed, may be used regularly every year, and the advantage will soon be most unmistakably apparent. There are exceptions to this rule as to every other; some few plants do better in a somewhat poor soil, but they are the exception.

Vegetables, Fruit, &c.—It may as well be here stated that the gardener in town will find it not nearly so satisfactory to attempt to grow vegetables or fruit as flowers. Potatoes do no good at all. Cabbages grow to such a length of stalk, with so little on the top of it, that the only result is a derisive laugh on the part of one's neighbours instead of a succulent dish on one's table. Even Runner Beans, at least in the heart of London, drop nearly all their blossoms, though in the suburbs, or even a moderate-sized town, they are a capital crop if sown in good rich soil, and carefully trained in a favourable position. Dwarf Beans (French) often produce a fair crop, and these, with a little small salading grown in frames, are about the most suitable crop to attempt. The best dwarf Bean to grow anywhere is the Canadian Wonder. These last, such as Mustard and Cress, Onions, &c., may be grown in frames or boxes covered with glass, for if grown in the open your salad will be so black by the time it is fit for use as to be almost uneatable. A few roots of Rhubarb, planted in a well-manured border, will yield a good gathering, especially if forced or protected by means of large boxes covered with glass, or forcing pots, &c. Vegetable Marrows will sometimes set a few fruit if well grown, and Strawberries do, with care, almost better than anything. A short chapter upon the best method of growing these will be found farther on. Cucumbers, &c., almost invariably turn yellow and drop off when 2 in. or 3 in. long. Hardly any kind of berry fruit will set. Even Solanums, grown for their berries, will never keep more than three or four on, no matter what care may be taken of them. Besides Strawberries, Grapes are the only fruit found to give any appreciable result, and these, unless protected by glass, are so dirty by the time they are ripe as to be scarcely eatable. The obvious conclusion is, with the few exceptions mentioned, to leave such unsatisfactory subjects alone, and confine your efforts to the production of flowers only. Fruit-bearing is a stage beyond flowering; it is as much as the plants can do to reach this stage successfully without going any farther.

However, having determined to grow something, the ambitious amateur's first inquiry is—

What to Grow.—Strange as it may appear, there are some plants that will grow almost without any care at all to all appearance as well in a town as in the country; and again there are others that all the care and expense that can be bestowed upon them will fail to save from an untimely end. Between these two extremes are a vast number of subjects that will give more or less good results, according to the more or less favourable situation in which they grow, and the amount of care and attention bestowed upon them. Of course in the suburbs of a moderate-sized town many things will grow and flourish with ordinary care which it would be of no use attempting to grow in the heart of London. Let it be understood, however, that all my remarks on town gardening, unless where an express exception is made, apply to situations in the heart of large towns, where miles of streets and houses intervene between them and the green fields in every direction.

I have always found that the most unsatisfactory class of plants to attempt to grow in such places are, with few exceptions, our common old-fashioned English flowers, such as Violets, Pansies, Roses, &c. Roses will not grow, even when protected by glass and every possible care taken of them, and especially in London; they only drag out a miserable existence for a year or two, and then inevitably perish. On the other hand, many exotics, such as Petunias, Lobelias, &c., will grow and flower almost as well as if in the country. All forest trees, especially the Oak, Ash, Elm, &c., cannot exist in the smoke of large towns. The common Primrose and the Cowslip may, however, be taken as an exception to the above rule. These will not only grow, but also flower very satisfactorily in any town, if planted in good rich loam and a little care taken of them. To these may be added the common wild blue Hyacinth (not the Harebell), which makes a very pretty show each spring.

However, to sum up, grow only suitable plants of which lists will be given, and take care, also, to grow only the best and most vigorous varieties. Grow them from the very best seeds or cuttings, that is, if you grow your own; and the best, and consequently most expensive seeds will often be found the cheapest in the end. Give your plants the very best of soil and everything else you can afford, and constant attention,

with untiring care, will be sure to produce good results. The watering-pot and syringe will be your best allies. Keep them going constantly in anything like dry weather. Here it may be remarked that, as a rule, for the town gardener, seedling plants will give much better results than those raised from cuttings, as they grow and flower so much more strongly and freely. Of course when you have a good variety of any flower it is advisable to propagate and preserve it by means of cuttings, but the winter in large and smoky towns is such an ordeal, that after a few seasons anything that is not of a very robust description will have become so debilitated as to be almost worthless, at least such is my experience. Therefore grow all such plants as Petunias, Lobelias, Verbenas, and all such plants as give good results as seedlings from good seed freshly every year. Whatever you must preserve through the winter, even such things as hardy perennials, &c., keep as far as possible under glass. B. C. R.

ROSES.

Tea Roses in Pots.—Those plants that have been prepared for late autumn-flowering, as recommended through the spring and summer, will by this time have made good growth, the extremities of the young shoots being set with a number of buds in different stages of development. The plants should, before being taken in, have their pots well washed, and if there be the slightest trace of aphides, red spider, or thrips about them, they ought to be syringed with Gishurst Compound, at a strength of 2 oz. to the gallon; this will be better for the purpose than anything else, for it will not only destroy the above insects, but mildew as well, and at this strength will not injure either the leaves or the young buds. After the plants have been washed in this way, and the mixture allowed to remain upon them for half-an-hour, they should be well syringed with clean water to free the leaves from the white sediment left by the Gishurst. It is a good plan to prepare the solution two or three days before it is applied, as in this way it leaves much less sediment upon whatever it is used. Tea Roses are far the best for autumn blooming managed in the way above described, as not only are the flowers finer, according to their respective kinds, than can be had from any other description of Roses, but they give a succession that no other varieties will afford; the blooms cannot be expected to attain the size they will in spring and summer, but in the half-open bud state they are invaluable for making up into bouquets, buttonhole flowers, or for filling small vases.

Coal Ashes in the Garden.—It has long been known that coal ashes have the effect of mellowing heavy soils, particularly clay. A clay may thus be greatly improved in texture. It has been held that the fertilising properties of coal ashes are small; repeated analyses have shown this. Yet, used as they have been in gardens, without other manure, the effect has been such as to lead irresistibly to the conclusion that they develop in some way a considerable amount of fertility. All cannot be accounted for by the mechanical improvement, as in cases where this is not lacking the effect is still present, and apparently undiminished, if not sometimes increased—in this case acting seemingly as wood ashes do, requiring other (organic) fertility to aid if full results would be obtained. I was surprised, early in the season, on seeing unusually fine Tomatoes and Beans, to learn that the only manure used for them was coal ashes, scattered in the garden to get them out of the way. This was practised for several years, and no manure other than this had been used. My own experience is confirmatory, but I find that the effect is not immediate. It is more tardy than in the case of wood ashes, whose potash and soda act promptly. I would recommend that coal ashes, instead of being thrown away, be used in gardens, removing the coarser parts; also on Potato ground, always mixing them well with the soil, and as early as the ground will admit, and to be repeated yearly, thus giving time for effect upon the soil. I find the best success where the ashes have been applied for several years. The second year is sure to tell, even where thrown upon the ground and left to lie there undisturbed, as I have abundant evidence. But the place for full action is in the soil.—*Country Gentleman.*

Primula denticulata.—This is a hardy plant from the Himalayas, and has long been grown in pots in greenhouses for early spring flowering. When well grown it throws up abundance of stout stalks surmounted by round heads of pretty lilac blossoms. If planted out-of-doors the soil needs to be deep, well drained, but moist. It is best taken up and parted every two or three years. When grown in pots for windows or greenhouses, the best way is, when the plants have flowered, to divide them a little,

Himalayan Primrose (Primula denticulata).

and plant them out in good rich soil. Lift them and pot them in September, give plenty of air and water, and keep them free from green fly.

Anemones.—With us these flower well and are not the least trouble. In mild seasons they bloom from the middle of January to May, and in the early days of spring, when the weather is sunny, large patches of them are a mass of blossoms. These patches are never disturbed, but go on flowering from year to year without any other assistance than a top-dressing of manure in the autumn, care being taken, however, never to cut the leaves off after the flowers are over until they are quite withered. The seed is sown directly it ripens (we collect it carefully on a dry day) in a bed in which garden soil is mixed with plenty of sand. The sowing consists of merely scattering the seed on the surface and sprinkling it with sand. In dry seasons water should be occasionally given. The young plants frequently flower in the autumn of the same year; they can be planted out then or reserved for the spring. We have all shades of colour from scarlet and crimson down to white and violet, with many shades of mauve. Anemones keep fresh in water for many days; they furnish us in spring with an inexhaustible supply of cut flowers for the house.—N.

Fuchsias Out-of-doors.—I believe that there is scarcely one of the cultivated pot Fuchsias that will not survive our ordinary winters with very little care. Although they die down, they spring up in summer and bloom in autumn with a beauty and a vigour never seen in the case of a pot plant. They should be turned ou by the hundred in shrubberies and among herba ceous plants. One of the most beautiful fo this purpose is a variety called Wave of Life, i my opinion one of the best Fuchsias in existenc —T. W. O.

WINTER FLOWER GARDENING.

At the present time, when summer flowers a being cleared off the beds and their places fille with spring flowers, bulbs, &c., it may not b out of place to give a list of the best subjects have found to make a really good effect in winte so that when the beds are planted they may pr sent a furnished, cheerful aspect for the who season. They are selected as being perfectl hardy, and if procured from nurserymen wh make them a speciality, such as Messrs. Veitch Osborn, or Lee, who have exhibited them o several occasions, they will be found so we rooted from the frequent transplanting the receive, that there is no fear of their taking an harm by removal.

For Pyramids for furnishing corne of beds, large vases, &c., the following a first-class:—Biota (Arbor-vitæ) argentea, s ver speckled; B. variegata, gold speckled; B elegantissima, bronzy-gold; Cedrus Deodora all spica, silver; Cupressus Lawsoniana alba pe dula, white and grey; C. L. alba spica, whi and grey; C. L. argentea, silvery grey; C. aurea variegata, golden blotched; C. L. erec viridis, bright green; C. L. ochroleuca, ye lowish-white; Cupressus macrocarpa Cripp green speckled; C. m. sempervirens variegat green and gold; Euonymus japonicus D d'Anjou, striped; Juniperus chinensis aure straw coloured; J. drupacea, bright gree J. argentea variegata, silver blotched; J. v giniana argentea, white speckled; J. virginia elegans, dark green and cream colour.

For Carpeting the Surface, dwa bushy plants of the following are excelle either by themselves or in conjunction wi spring-flowering plants and bulbs: Abies aure gold; A. Engelmanni, grey; Aucubas in varie of foliage; A. vera fœmina, red berries; Bio aurea, golden-bronze; B. filiformis, green; perfecta, green and gold; B. semper aure bronze; Berberis pygmea, green; Buxus na variegata, silver-green; Euonymus latifoli argenteus, striped; E. aureus elegantissimu gold; E. rotundifolius argenteus, silver; Retin sporas—cupressoides, ericoides, filifera, ju peroides, obtusa nana aurea, pisifera lute plumosa, p. alba spica, p. lutea, squarrosa.

For Low Standards as Centres f Beds the following are well adapted: Euon mus latifolius argenteus, E. l. a. elegans, vario sorts of plain and variegated Hollies, vario sorts of plain and variegated Ivies, vario sorts of Privet, Osmanthus illicifolius variegat O. i. aureus, Portugal Laurels, Laurustinus and Bay.

These are all cheap, ranging from 6s. to 1 per dozen, and if carefully planted in the serve garden will last for many years, and wh too large for beds will be available for growi into specimens or for forming shrubberies—fact, a good investment for owners of eith large or small gardens. J. Groom.

Linton.

Creeping Speedwell (Veronica repen —Nothing can exceed the beauty of this pla where a deep green is required in geometric c pet or scroll work; it grows amazingly fast, a scarcely exceeds in height a penny-piece, be rolling like Grass, for which in small intric flower gardens, where the scythe or machines co scarcely be employed, it is an excellent subs tute. It maintains its emerald green colour cold weather, the only objection to it, perha being the short duration of its blooming.—T.

Autumn Primroses.—Amongst ha flowers now in bloom might well be classed lovely single Primroses that are now throwi up their earliest blooms. There is a freshn and beauty in these blossoms that are as acce able now as in the spring, for the summer is pr tically the winter of the Primrose, as it d not suffer in cold weather, and, except in sev frost, is always active. Strange to say, spite of the heat of the summer, the Primro in the open ground here have suffered but lit and are now covered with robust foliage; thi

the precursor of strong heads of flowers, the earliest of which are now developed. Primroses succeed well in the open ground if removed but once in the year, and that in the autumn. It is a mistake to allow them to remain untouched too long, as in the course of growth a woody stem is developed that eventually produces decay. When lifted and divided each autumn the plant has time to become established before the spring blooming period, and at the same time the development of an elongated stem is prevented.—A. B. H.

Plants for Shrubbery Borders.—Having seen inquiries in GARDENING about plants suitable for shrubbery borders, I beg to say that I find the yellow Daffodils to grow very well and look very bright and pretty in the early spring, besides Snowdrops and Crocuses. Later on I have always a quantity of yellow Turk's-cap Lilies, afterwards some large blue Monkshood and yellow day Lilies. The common blue Centaurea will flourish also, but it is a very straggling, untidy plant when flowering. I have two rows of London Pride along the edges of the borders and Thrift, both of which do remarkably well, and have the advantage of being hardy and evergreen all winter. The common Fumitory (Fumaria officinalis) thrives and flourishes on the very roots of trees, and has a pretty, graceful leaf. Evening Primroses (Œnotheras) and Sweet Williams will grow in some spots also.—KATHLEEN, *Didsbury*.

When to Move Tree Pæonies.—I notice that these should never be transplanted except in the autumn. If transplanted at any other season they are apt to perish either during the summer or in the ensuing winter. It seems a pity that these beautiful plants should be so little grown. They are at once among the most showy and striking of all hardy plants. Specimens of them in the herbaceous borders and beds are very striking; but massing them among shrubs or as separate groups on lawns is still more striking and effective. As soon as their leaves fall in the autumn is the only safe season to divide or move them.—D. T.

Hardy Flowers for Mixed Border.—Delphiniums are amongst the most showy of hardy perennials. As they under good culture attain a height of from 5 ft. to 8 ft. they are suitable for the back row of a mixed herbaceous border. They require rich soil, and if the flower-stalks are cut off as soon as the flowers fade, and the plants well watered, they will throw up a second crop of bloom. The Phlox is also a grand subject, exhibiting colours both chaste and brilliant. At the back of the border we would plant some climbing Roses, such as Adelaide d'Orleans, Félicité Perpetué, Gloire de Dijon, Ruga, climbing Jules Margottin, and climbing Victor Verdier; also Clematis of kinds, such as Jackmani, rubro-cœrulea, rubella, lanuginosa nivea, lanuginosa candida, and Lady Caroline Neville. These should be planted at intervals of say 6 ft. or 8 ft., and should be trained to poles some 8 ft. high. Once planted, they will last for years, merely requiring a good dressing of manure yearly. Of vigorous free-flowering subjects may be mentioned Coreopsis lanceolata, Rudbeckia Newmani, Echinops ruthenicus, Buphthalmum salicifolium, Lupinus polyphyllus, Monarda didyma, Lythrum salicaria splendens, Epilobium angustifolium, Aster longifolius formosus, A. Amellus bessarabicus, and Campanula latifolia. Amongst those of more moderate growth may be mentioned Œnothera Fraseri, Œ. riparia, Achillea Ptarmica fl.-pl., Alstrœmeria aurantiaca, Anemone japonica (pink and white), Centranthus ruber, Geum coccineum, Hemerocallis flava, H. disticha fl.-pl., Gentiana acaulis, and Tradescantia virginica. Dwarf-growing subjects consist of Funkias of kinds, Campanula turbinata, C. carpatica, C. pusilla, Potentillas, Sun Roses, Cardamine pratensis fl.-pl., Gentiana acaulis, Saxifraga granulata fl.-pl., Orobus canescens, and Lychnis Viscaria splendens. Then there are the many free-flowering and effective varieties of bedding Pansies and Violas, flowering bulbs, such as Daffodils, Snowdrops, Tulips, Scillas, Triteleia uniflora, and Fritillarias. Hardy annuals may also be sown in September and March, and half-hardy in April and May. A few climbing Tropæolums, Convolvulus, and Canary Creeper might be sown here and there training them to 4-ft. stakes. Stir the groun, well before planting, and plant either before the latter end of November or early in March.—J. C. B.

DWARF NASTURTIUMS.

THE exceedingly brilliant colours seen just now in these gay, but tender, garden plants resemble in one respect the leaves of the Virginian Creeper, which are never so beautiful as just before death. A sharp white frost may come at any moment, and destroy not only the beauty of the flowers, but also the life of the plant. Modern styles of bedding have hardly dealt with the Nasturtium, especially the dwarf kinds. Such rich, bold colours as are found in the compactum strains—sorts that must not be confounded with the Tom Thumb kinds—are marvellously effective when seen in masses, and if the soil be somewhat poor so much the greater the mass of bloom. Bedfont Rival, a deep, brilliant orange-scarlet, has large flowers of fine form, and it is a robust grower. Beauty of Malvern is very floriferous, but the flowers are smaller and have less depth of colour. Hunteri flowers exceedingly freely, but the growth is small and dwarf; this is better fitted for moist situations, whilst a robust kind, such as Bedfont Rival, does remarkably well under drier conditions. The most effective yellow, the flowers of which are profusely produced, is compactum aureum, a good companion to the scarlet kind. Lustrous is an especially rich-coloured kind, having deep crimson-scarlet flowers and

Dwarf Nasturtium (Tropæolum).

leaves of a dark hue. A very pleasing and altogether unusual colour is found in carminatum, a rich carmine-red variety of the large-flowered scarlet kind. The forms of compactum are so constant, that they are never without flowers from first to last. In this respect these outshine the Tom Thumb kinds, which have a short season of flower and then collapse. They can be had good from seed and generally true, but it must be understood that actual truthfulness as regards varieties can only be ensured by means of propagation by cuttings. Fortunately, cuttings are furnished by the plants in great abundance, and these will strike freely anywhere under glass if put in during autumn. A few dozens put into store pots will yield a large number of cuttings in spring, and these spring-struck plants make the best for summer bedding. Plants from cuttings also make less leafage, furnish more bloom, and, curiously enough, produce little seed, but what is so produced may be relied upon to fairly reproduce the parents if no other kinds of Nasturtium are growing near. In growing these for seed it is the practice to weed out everything from the stock that is not true. With such care the truthfulness of the seed produce may be fairly maintained. As the plants cover the ground rapidly, it is found advisable to rake the surface of the soil smooth and fine, so that when the seed is dropped, as it is doubtless will be largely during the summer, it can be gathered up by hand without much difficulty. The Tom Thumb kinds are sown in large breadths in the open ground in spring, but the compactum race grow too freely when so raised, and are best produced under glass and then planted out. Treated thus, they bloom earlier, are more compact, and can be planted out to succeed spring bedding plants. All who appreciate rich masses of colour will find these dwarf Nasturtiums or Tropæolums worth cultivation.

D.

FRUIT.

Free Bearing Pears.—There was mention made lately in GARDENING ILLUSTRATED of three Doyenne Boussock Pears weighing 1½ lb. I have a Doyenne du Comice Pear tree 9 ft. in height, which has given twenty fine Pears, three weighing ½ lb. each, and one 10 oz., most of the others 7 oz. and 6 oz., and none less than 4 oz.—C. T., *Broxbourne*.

Rust on Grapes.—I believe one of the chief causes of this is keeping the house too hot just after the berries are set, and not giving air early enough in the morning to take the moisture arising from the house away before the sun gets on the glass. I have found Grapes very bad with the rust before they have been touched with the scissors or hair of the head or the syringe, but since I have been more careful in giving air I have not been troubled with any rust on Grapes.—G. T.

Plum Reine Claude de Bavay.—This is a good Plum. Any one who thinks of planting Plums against a wall will do well to try this sort. It is a first-rate dessert Plum of exquisite flavour, ripe in the beginning of October, an excellent bearer, and not likely to crack.—T. WINFIELD.

Gooseberry Caterpillars.—Looking over an old book of practical receipts, I find the following for destroying caterpillars on Gooseberry trees: Get a quantity of Elder leaves and boil them in as much water as will cover them until the liquor is quite black, then clear and cool it, and to every gallon of this liquor add one gallon of Tobacco water; when the trees are quite dry, lay it on with a fine rose waterpot, and in ten minutes the caterpillars will fall off. Another way is to syringe the trees with a decoction of Black Hellebore. The caterpillars will eat poisoned leaves, and thereby be destroyed.—H. F.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

October 25.—Potting Lily of the Valley and Hoteia (Spiræa) japonica; planting Ivy about Fernery; Hyacinths and Tulips amongst annuals; and making up failures in Lettuce beds; moving Pelargoniums from frames into houses; putting glass protectors over intermediate Stocks; placing Roman Hyacinths and Roman Narcissi in heat weekly; putting all cuttings from frames into Vineries; getting Mignonette into pits as fast as possible in order to get frames at liberty for Lettuce; sending in Damsons; also Keswick Codlin Apples for jelly; manuring and digging about standard Roses; filling bins with soil in potting shed; turning some long manure, and watering it to sweeten it so as to be ready for hotbeds for Seakale and Rhubarb; digging vacant grounds; putting protection round Calceolaria pit; hoeing among Coleworts.

Oct. 26.—Taking up Gladioli; putting a few of the earliest Cinerarias into a warm greenhouse; pruning and nailing Morello Cherries; cleaning inside of tree guards in pleasure ground; getting all Pea stakes pulled up and put away.

Oct. 27.—Filling up blanks in Cabbage plantations; taking up and replanting some young Cherries in order to check over-luxuriance and induce them to fruit; getting up Dahlias, the tops of which are all killed; rearranging conservatory; moving an Araucaria imbricata; finishing nailing of trees on north walls; taking up Endive and putting it in orchard house; stacking Carrots and Beetroot; giving winter Cucumbers 1 in. of top-dressing; examining all young Pelargoniums in pits, and clearing them of dead leaves and flower-stalks.

Oct. 28.—Planting frames with Violets; also planting Cauliflowers under hand-glasses; staking all Mignonette; putting Gladioli into Vinery or other dry place; pruning and nailing Cotoneasters; hoeing and earthing up Cabbage.

Oct. 29.—Potting Schizostylis coccinea; shifting herbaceous Calceolarias into 6-in. pots; turfing round Roses after having manured them; taking up stock plants of Balm and Blue Salvia; cleaning and pruning Peach trees in early house and otherwise ready for starting; hoeing between autumn Onions and Spinach; rough-raking flower borders.

Oct. 30.—Saving some seed from the best varieties of Balsam and Celosia; sowing Cucumbers for February; potting some Roses in two parts good loam and one part manure; taking up Hollyhocks; putting Achimenes under the pipes in Vinery: Snow's winter White Broccoli ready for cutting; pulling up all bedding plants; cutting dead wood out of Yew trees. Plants in flower—scented-leaved, scarlet, and pink Pelargoniums, Mignonette, Stocks, Heliotropes, Scutellarias, Amarantus, Narcissus, Chrysanthemums, Schizostylis, scented Verbenas, Justicias, Pentas, Primulas, Coleuses, Fuchsias, and Plumbago.

Glasshouses.

The amount of bloom at present will unavoidably be smaller than at any other time during the season. This is always the case until Chrysanthemums come in; but where a sufficient number of Camellias exist to admit of their growth being so regulated as to have a portion opening their flowers about this time, not only will they be found most useful for cutting, but when in a healthy thriving condition, furnished with plenty of foliage, the combination of leaf and bloom which they possess makes them second to no plants in cultivation. The autumn-flowering Veronicas, too, that were lifted and potted some weeks back, will be an acceptable feature now for many weeks. Amongst hard-wooded plants of the easiest possible growth that flower at this season may be named the Croweas, which, although never making such a display at any one time as some plants will, still keep on producing their pretty pink, star-like flowers to the end of the year. These, with Tetratheca verticillata, the red-flowered Leschenaultias, Cassia corymbosa, and some of the Correas, will help to relieve the sombre appearance of the green foliage, which at this time predominates. It is now also that plants grown both as standards and in bush fashion of Habrothamnus elegans and Heliotrope will be found most useful; the little extra warmth kept up in greenhouses will assist the free development of their flowers. These, in company with other quick-growing subjects, though not requiring the assistance of manure water nearly so much as during the principal growing season, will nevertheless be benefited by a weak application once a fortnight. The autumn-blooming Salvias will likewise be available, and will bear standing close amongst larger-growing plants without injury. Any old examples of Primulas that have been kept on from last year will be useful. Where good healthy examples of Oranges exist there is no period of the year when the appearance of their fruit in its different stages is more acceptable than during this scarce time for flowers. Solanums, also, where sufficiently early to even have a portion of their berries assuming the ripened colour, will be of service. The many fine-leaved plants it is necessary to introduce at this season to give conservatories a furnished look should be kept scrupulously clean; the washing and sponging consequent upon this have the double advantage of keeping the leaves in a sightly condition and freeing them from insects, which, where even the highest keeping is maintained, entail more incessant labour than anything else connected with plant cultivation.

Cyclamens.—Pay every attention to these, both the older plants as well as those raised from seed, which have not yet flowered. Where there is not the means at command of growing them in a pit or small house, either wholly by themselves, or where the temperature can be regulated so as to make their requirements the first consideration, if a few could be moved to a position where they can be kept at about 45° in the night, with a day temperature proportionately higher than that of an ordinary greenhouse, they will come earlier into bloom.

Chrysanthemums.—There is often a difficulty with Chrysanthemums where sufficient and suitable accommodation does not happen to exist, especially in the north of the kingdom, where, without some protection, it is not safe to trust them out-of-doors even so late as this; for although hardy, still blooming as late as they do, if their advancing buds are subjected to many degrees of frost, they will be severely injured. On the other hand, they do better with more air than at this season is given to an ordinary greenhouse, for if kept at all close it has the effect of drawing out the flower shoots weakly, and if any mildew is present upon them the absence of a free admission of air day and night tends to cause its spreading, and if put in houses, already in many cases too full of other things, the Chrysanthemums not only get injured themselves, but do harm to other plants as well. Where there happens to be a Vinery in which the Vines are denuded of their leaves, it will be just the place for them for a few weeks until their flowers are about to open, leaving plenty of air on night and day unless there is an appearance of sharp frost. A place of this kind not being available, spare hotbed lights put over a temporary framework up to a south wall, with a loose piece of canvas or mats that can be put up in the nights to protect the ends and front, will answer all the purposes required. Glazed lights being wanting, an ordinary blind, such as that used for shading plant houses in summer, working on a roller so as to let down in the nights and expose them in the day in fine weather, is the next best thing to resort to. Continue to thin out the buds as they get large enough to lay hold of. Much thinning of the flowers for ordinary use is looked upon by many as unnecessary, but this view is far from being correct, as in the case of plants only wanted for decorative purposes if the flowers are reduced to, say, one-fifth of the number formed, these will be very much better than the greater quantity which would be less fully developed, and individually not possess near the substance to enable them to last long which the thinned examples have. The plants will now be benefited by manure water, but for the benefit of young growers it may be observed that although Chrysanthemums are exceptionally gross-feeding plants and enjoy much more moisture in the soil than most plants will bear, still it will not do to keep them too wet, or the roots will be damaged. Whatever stakes and ties are necessary should be given them, for such giving the preference to dry Willows or Hazels rather than painted sticks or the ugly deal often used without paint. Keep a look-out for mildew and dust any affected leaves that are detected, or it very soon will spread with a rapidity that will render the plants bare and unsightly at the time of blooming, with a proportionate weakening influence on the flowers. Should worms have got into the pots let the soil get a little dry, and then give a good soaking of clear lime water, which will dislodge them.

Flower Garden.

Dahlias.—These are flowering in the greatest profusion. We could ill spare any of them, either double or single, but the latter are most useful for decorative purposes when cut from the plant. Paragon is merely a variety of D. variabilis; but be that as it may it reminds us of the beautiful single flowers about which some of the old florists yet alive can speak. The colour, size, and shape of the ray florets are beautiful in the extreme, and if flowers of similar merit could be obtained now, they would be as eagerly purchased as Paragon has been. Dahlias have not suffered in the least from frost as yet, and it is still necessary to tie out the stems, and to see that the ground is kept neat and clean underneath them.

Gladioli.—These, like Dahlias, still continue to produce flowers, but the cold nights are rather more trying to them than to the Dahlias. While the weather is dry the bulbs may be left in the ground, but it is well to see they are taken up should a change occur. The ground intended for planting next year should be prepared at once. Use rotten manure liberally and trench it at least 6 in. below the surface. Trench the ground two "spits" deep, shovelling the loose earth out each time as well. Give two layers of manure—one in the bottom of the trench, the other when a spit and shovelling of earth have been laid over it.

Phloxes and Larkspurs.—Do not cut the stems of these over while the leaves are still green, but as soon as they decay they may be cut over close to the ground. See that the ground is kept clear of weeds, and that the hoe is worked amongst the plants when the ground becomes hard on the surface.

Tulips.—Ground for these must now be prepared, as planting time is at hand; the surface of the beds cannot be turned over too often when they are dry. Look over the bulbs and see that they are in good condition. Some sharp sand and good rotten turfy loam should be in readiness.

Fruit.

Vines.—The fine weather that has lately prevailed has wonderfully assisted the ripening of Grapes, seeing that fire-heat could be applied with free ventilation. Such treatment should still be continued till the fullest maturity is ensured, and then there will be no fear that the Grapes will not keep, provided, of course, they belong to the late-keeping class, such as Lady Downes, Alicante, Muscat of Alexandria, Mrs. Pince, Gros Colmar, &c. As soon as fully ripe the only essential condition to good preservation will be to keep the atmosphere dry, and always a few degrees higher than the outside temperature, which will be certain to hinder the settlement of moisture on the berries. They would keep well in any dry room from which frost and damp can be excluded, and in cutting them all the wood in front of the bunch should be left on, as this serves, as it were, as a safety-valve to prevent too much water being taken up by the berries. There is also another reason why such Grapes should now be cut, and that is the well-being of the plants that have, in many cases, to be wintered in Vineries, and which, till the Grapes are used, have to be kept too dry. Plants and ripe Grapes cannot by any possibility be made to agree satisfactorily together. Vines that have shed their foliage should be at once pruned; this done, the houses should be cleaned, and if necessary repaired and painted. The borders should then be top-dressed and mulched.

Vegetables.

Every moment that can be devoted to stirring the ground amongst growing crops will materially assist to consolidate a growth that will the more effectually carry them safely through the winter. Lettuces, Onions, Carrots, Turnips, and Spinach will all be much benefited by the bestowal of such labour. The weather is also most suitable for finally earthing up the earliest Celery, tying up a quantity of Endive for blanching, and moving and heeling in the same, either in frames or in some sheltered nook, where temporary protection can be easily applied. Root-storing can also, while the weather is dry, be more expeditiously done than when it is unfavourable. Salsafy, Scorzonera, and Beet ought now to be stored in dry sand in a cool shed, or else in clamps the same as Potatoes. Beetroot is sweetest if wintered where it is grown, but protection must be afforded it, which is sometimes inconvenient. Carrots we prefer to house and keep as dry as possible. Parsnips should always be left in the ground till required for use, as the severest frost does not harm them in the least, and the difference as regards their flavour is much in favour of wintering them in that way. Select a few of the most mature crowns of Seakale for a first batch, and other roots may be dug up and again heeled in to induce partial rest before forcing. Asparagus plots may now have a final clearance; cut the stems off to the ground line, then weed, and afterwards stir the surface soil with forks to a depth of 2 in. or 3 in., and the first hard frosty morning give a good dressing of the best manure available; of course those roots that are intended for the present season's forcing need not have manure applied to them. Cabbage, Coleworts, Cauliflowers, Lettuces, and Endive may all still be pricked out, selecting only the most sheltered spots in the hope of wintering them successfully. For the sake of neatness clear away all refuse vegetable matter as soon as the crop is exhausted, and let the ground be dug, ridged, or trenched as soon as it conveniently can be. Unfortunately, there is a disposition amongst us to let the kitchen garden take its chance, a feeling of some such sort as what matters it about neatness so long as the crops are good and supplies forthcoming.

CALCEOLARIAS FOR THE FLOWER GARDEN.

In the summer decoration of flower gardens, Calceolarias, when in good condition, are as yet unrivalled amongst yellow-flowering plants, and as the manner in which they are wintered has an important bearing on the following season's display, a few remarks on the method by which good plants may be secured may not be inappropriate at this, their best season of propagation. I am no advocate for fixed dates for any special operation, for seasons and localities necessarily interfere with such, and cultivators should in all

cases be guided by their own experience, but here October is quite early enough for getting in the principal batch of this useful plant, and our mode of proceeding is as follows :—

An ordinary garden frame is set on a solid bed of coal ashes, in a position sheltered from the north and east, but fully open to the south ; in this is put about 4 in. of loamy soil, sifted moderately fine, and pressed down firm and level, finishing off with ½ in. of coarse sand ; then it is well watered to settle the soil firmly, and healthy-growing shoots for cuttings that have not produced flower are inserted as speedily as possible in rows 3 in. apart each way ; the lights are then shut close, and shaded during bright sunshine, but the lights are removed entirely at night to prevent flagging, and as soon as they will bear exposure without suffering in any way the lights are removed altogether, except during heavy rain or frosty nights. We never put the lights on until the thermometer gets close down to the freezing point, but as soon as there is danger of severe frost the frames should be well protected on both the sides and top with Fern, mats, or litter, removing them as soon as the thermometer rises again, as the less they are coddled the better for the health and vigour of the plants, but in very severe or protracted frosts they will receive no injury if covered up for a week or ten days in midwinter, when they should be at rest, and when growth is positively injurious to their future progress ; but as the days begin to lengthen and solar heat increases the growth will soon become rapid, and they must on no account be allowed to suffer from drought.

In February they will require stopping by pinching out the points, leaving two pairs of

Cutting of Shrubby Calceolaria.

leaves, from the base of which four strong shoots will soon extend, which must likewise be stopped as soon as they are of sufficient length. By the end of March they will be dwarf, sturdy bushes, requiring more space for top growth, and the soil will be a perfect mat of roots. If the beds intended for their reception have been duly prepared by deep cultivation and are unoccupied by spring flowers, they should be planted out at once, when they will become thoroughly established before dry, hot weather sets in. Temporary protection must, of course, be provided, evergreen branches being the best material for defending them from the wind, which is more to be guarded against than frost ; for, although a few degrees will kill plants that have been drawn up in warm structures, they will not affect those that have been treated as above described. The beds should have a good deep mulching of rotten manure, leaf-mould, or Cocoa fibre in May, in order to retain the moisture in the soil. With us, in the beds the Calceolarias are the first to be effective and the last to be cleared off. Where spring gardening prevents such early planting as above mentioned, the only remedy is to transplant into temporary pits prepared in the same way as for cuttings. The benefit of confining the roots to a moderate depth of soil by means of a coal-ash foundation will be fully apparent at the time of removal, for if the soil be moderately adhesive and full of roots, the whole of it will remove in square blocks if cut down between the rows, and the plants will scarcely experience any check, but start into vigorous growth immediately. When it becomes necessary to increase Calceolarias in spring, a close box or hand-glass may be put on a cold bottom in the greenhouse. The plants from which the cuttings are to be taken should have 55° of heat to draw out the cuttings, which are best cut and put in in the same way as Verbenas ; give air every morning and a slight sprinkling overhead with water. As soon as they are rooted, gradually harden them off.

G. R. M.

GLASSHOUSES & FRAMES.

HINTS ON TREE FERNS.

The cultivation and description of Tree Ferns are so simple, that it is almost useless to allude to them, but as questions are sometimes asked under this head, the following may perhaps be useful to some readers of Gardening Illustrated :—

For compost, use good fibrous peat of rather a spongy nature intermixed with Sphagnum Moss, fresh or decayed, and place a good layer of the latter over the crocks in place of rough peat, which is sometimes used ; keep the trunks constantly syringed winter and summer, but more especially when making their young fronds ; at the same time keep them well shaded from the sun. If pots or tubs are used, let them be as large as convenient, as Tree Ferns are strong rooters, but where they can be planted out and treated as above, they will grow almost as luxuriantly as if in their native habitats. A very novel and pleasing effect might be produced by planting the Creeping Fig (Ficus repens) against the trunk, as it is particularly ornamental on the tall growing varieties ; the rough porous surface will allow the roots of the Ficus to attach themselves readily, and it will not only clothe the trunk with a living verdure, but also assist to retain moisture on the stem of the Fern, which is very advantageous. During the hot months the small-leaved Silver Ivy is also useful for the same purpose. Among varieties of Tree Ferns may be mentioned

Dicksonia antarctica.—This is not so rare as many other Tree Ferns, but is probably the most useful from its hardiness of constitution and freedom of growth ; the graceful fronds are of a lively green, from 3 ft. to 7 ft. long, and from 1 ft. to 2 ft. wide, and the crown of the trunk is covered with silky hairs of a glossy auburn.

Cyathea dealbata.—This is one of the finest Tree Ferns, both on account of its upright, handsome trunk, and also for its fine spreading fronds, which are completely covered on their underside with a silvery-white substance which does not wash off ; the stipes are of a glaucous hue, and the trunks are thickly covered with chocolate-coloured hairs, and are generally of equal diameter from the base upwards ; a few have slender stems and with their elegant arching fronds strongly resemble in general outline the elegant Cocos plumosa.

Alsophila australis.—The fronds of the Alsophila australis do not spread so wide as those of Dicksonia antarctica or Cyathea dealbata, but for compactness of growth and symmetry of outline this variety has few equals ; the fronds are of a deep green, and somewhat horizontal in their growth ; the base of the stipes are thorny, and of a dark brown, or in some cases black. The trunks are particularly straight, and of equal thickness throughout, and produce a fine effect in the conservatory.

Alsophila excelsa.—This is one of the most rapid growers of all known Ferns ; it is of the easiest possible culture, and a noble object in any stage of its growth ; the fronds are of a bright green, very large and spreading ; the stipes, which are upright, are densely clothed with light-coloured chaffy scales, 1 in. long at the base, and gradually diminishing in size towards the tip of the fronds. A very effective plant for a cool house.

Cyathea medullaris.—This is truly a giant Tree Fern of noble port. The trunk is densely clothed with black bristles, which interlace the bases of the stipes, and the latter are, when fully developed, as black and smooth as polished ebony. When young they are covered with a glaucous bloom or powder ; and there are, running parallel to each other, two white lines on the upper surface of each of the stipes, which are continued with slight interruptions to the extremity of the rachis. Cyathea medullaris is of rapid growth and of the easiest culture.

Cyathea Smithi.—This is decidedly one of the finest of the New Zealand Tree Ferns. Its trunk is slender when compared with those of other kinds ; the crown of fronds is more upright than horizontal, and are 3 ft. to 5 ft. long, very beautiful and plume-like in appearance. The stipes are clothed with cinnamon-coloured scales, and the fronds are a bright green and of easy culture.

Dicksonia squarrosa.—This is one of the most handsome and choicest of Tree Ferns. The trunks are slender and very upright, and almost black in appearance ; the stipes are thin as compared with others of the same class, and are densely clothed with light brown silky hairs. This plant has a very pleasing effect, beautiful appearance, and rare in collections.

Cambridge. Chas. Wood.

Ferneries in Towns.—How much more satisfactory such a Fernery as the one represented in our engraving (p. 406) would be in town gardens than the usual small greenhouse fitted with wooden stages and shelves, and on which are usually found a few flowerless Geraniums, Fuchsias, or long-legged Myrtles ! When the greenhouse happens to be in a sunny situation, then flowering plants may be grown with fair prospects of success ; but where, as is often the case, the sun never reaches the glass only for, perhaps, an hour in the day, then we would recommend a greenhouse with glass roof and brick or board sides to be turned into a Fernery similar to the one we now illustrate. Instead of the fountain, however, seats might be placed in the middle, and during the summer months such a Fernery would prove a deliciously cool and refreshing retreat. In such a place many of the choisest Ferns would luxuriate, especially if a little warmth could be given during the winter, but if no heat were used we have plenty of beautiful Ferns which would never suffer in the least from cold.

Spiræa palmata.—Exquisitely beautiful as this fine herbaceous plant is in beds and borders, it is even more so forced ; but to have the flowers well coloured they must not be allowed to expand in heat ; the plants should be set in a light cool house, where they can enjoy a moderate amount of air and receive plenty of water. So moisture-loving are they that they do best standing in shallow pans to intercept the drainage that runs through, which they soon re-absorb, and thus keep fresh without the attention they otherwise require to preserve them from flagging. I find that plants grown out in the open and dug up in the autumn are far preferable to any grown in pots, as the latter are never half so strong, and consequently do not bear such fine panicles of flowers. The best way to cultivate for forcing is to plant in very shallow trenches in a half-shady situation, as then they can be easily flooded with water occasionally, which is a great help in warding off red spider, so fatal to the foliage if they are allowed to become dry at the roots. The Spiræa admits of very ready increase by division, made any time before the plants have started much into growth, after which they should not be interfered with, as cutting through them then checks them severely, and is likely to end in their total loss. —S.

Solomon's Seal for Forcing.—For a choice bit of greenery, for the purpose of cutting during winter to associate with flowers, I know of nothing to equal the Solomon's Seal, as not only is it very lovely in the delicacy of its tints, but the stems are arched in the most graceful manner possible, and an additional attraction is the numerous silvery-coloured bells with which they are so profusely hung. This Convallaria is one of the easiest plants to force with which I am acquainted, as it responds readily to heat ; and the wonder is that it has not long since become a market plant, as it is specially adapted for the ornamentation of windows. They are grown largely for pot work by making beds or plantations in open half-shady spots on borders near a west wall ; where by digging plenty of manure into the ground, and cutting or dividing the large fleshy roots before planting, they increase at a great rate, and are ready for taking up again by the autumn. This we do as soon as the tops are fairly dead, when they are potted in rich light soil, and set in cold frames, to be drafted into heat as wanted, putting one or two into heat at a time. Besides being so serviceable for forcing, the Solomon's Seal is a capital plant for the

herbaceous garden, or for planting in the foreground of shrubs, or as patches near the margins of pleasure walks or rides, where it soon spreads and takes care of itself.—S. D.

ANSWERS TO QUERIES.

3254.—**Indian Corn in Pots.**—You must not expect to keep Indian Corn in pots throughout the winter unless in a warm house. You have made the mistake of sowing in September instead of sowing in April. If seeds were sown then, and plants grown singly in 6-in. pots, you might get very pleasing plants for a window or greenhouse, as the foliage is handsome and graceful. Some plants put out in the open ground, if of an early kind, will grow tall and produce both bloom and corn cobs by October, but there is not much ornamental merit about them. Being tender, the plants will not withstand the cold. Sow again early next spring. Of other plants for the window for the winter, it would be best to get some small ornamental Conifers and small Japan Laurels and Euonymus rather than bother with seeds. It would take years to raise such from seed, whilst plants raised from Acorns and Horse Chestnuts would be stunted and worthless.—A. D.

3266.—**Saving and Sowing Flower Seeds.**—Any fairly good garden soil will suit Indian Pinks, Stocks, &c., and the proper time to sow seed of all the plants named is in the spring. Verbena seed will need a little gentle warmth to help it to germinate, but Asters, Stocks, and Indian Pinks will come well if the seed be sown in a greenhouse or frame. To save seed from Asters it is but needful to cut off the flower-heads when the petals have quite decayed, lay them out upon paper during sunshine, and when quite ripe and dry rub them out, and cleanse the seed from all rubbish that can be fanned or blown out. Verbena seed must be treated in the same way. Stocks are pulled or the seed-pods cut when thoroughly ripe, and are hung up in the sun until quite dry, and then put into a canvas bag and threshed out, or if but a small quantity it may be rubbed out. If run through a fine sieve the seed is easily cleaned and fit to put by until sowing time. Indian Pinks ripen seed-pods gradually, that is, one or two at a time, and if these are picked off just as they burst, and are put into a paper bag, the seed when all is gathered may be rubbed out, cleaned, and put into a small bag or packet for the winter. Those who save their own seed should be careful to name all seed when cleaned up, and if they also put on the packets the proper time for sowing, it will serve to remind them when that season has arrived.—A.

View of a Town Fernery. (See page 405.)

3332.—**Red Potatoes for Exhibition.**—Much depends upon what is meant by a red Potato, as if it is meant to include all coloured kinds, then it has a wide application ; but if red ones only, then it is simple enough. Taking it in this latter sense, we put Triumph, an American kind, as the best, because it is the richest coloured, and fairly handsome ; but Red Emperor shows the handsomest tubers, and the colour is very good. Grampian is also a fine and handsome reddish Round, and is always a strong show kind. If red means coloured kinds, then of other coloured varieties we put Vicar of Laleham and Scotch Blue as the best purple Rounds, Radstock Beauty as the best red mottled Round, and Blanchard as the best purple mottled Round. We may add that in Kidneys, International and Woodstock Kidney are the handsomest show whites ; Mr. Bresee, a new American, and Garibaldi the best reds ; American Purple and Purple Ashleaf the best purples ; Heather Bell and Barron's Perfection the best mottled ; and Beauty of Hebron the best pink. Schoolmaster and Porter's Excelsior are the best white Rounds.—A. D.

3253.—**Mildew on Forget-me-nots.**—Mildew such as infests your Forget-me-nots is very prevalent this season on many plants in the open air. It is more obnoxious to the eye than actually destructive to the plants, but none the less it is well got rid of. Under ordinary house culture it may be destroyed by dusting freely with sulphur, but it is difficult to do this in the open air, as the first heavy rain will wash it off. Sometimes the mildew results from drought at the roots ; at other times from excessive moisture. We should advise that the plants in pots be first gently sprinkled with water, and then freely dusted with sulphur, and if the first dressing does not kill the mildew then try a second one. Perhaps the very best thing to do would be to get rid of the affected plants altogether, and get clean ones from another source.—A. D.

3263.—**Transplanting Rhubarb.**—We prefer transplanting Rhubarb after the leaves and stalks are decayed. You will find these disappear in a few weeks, and the plants may be removed then as soon as convenient. In doing so, it is well if a permanent plantation is the object, to cut the larger roots into two or more before replanting, and with a sharp knife to cut out the small crowns, leaving only three or four that are large and full. Such selected roots, if planted in rich manured soil, will soon get established and carry fine stalks. If the roots are lifted to be blanched or forced, it is well to allow them to remain whole, and to cut them up small for re-planting. After being forced, a little long manure should be laid over the newly planted crowns in the open air to protect them from severe frost.—A. D.

3280.—**Culture of Pyrethrums.**—These do not require any special winter treatment, as they are perfectly hardy, not needing the slightest protection during the winter months. They should be at once planted in the open ground, well stirring the soil intended for their reception. If the natural staple is at all light and poor, add to it some well decomposed manure, and in the spring give a good mulching of manure. The double Pyrethrums flower freely and continuously if kept well watered in dry weather, a good soaking of liquid manure being of great service. A light, open situation suits them best, and if so desired they may remain in the same place several years, but every spring the soil around them should be well stirred and a heavy coat of manure given. Where the natural soil is heavy, a little river-sand or leaf-mould mixed with it will do good. Cuttings taken off early in the summer, when the wood is tender, will strike freely in a cold shady frame. It is well to put in a few cuttings every year, so as to command a supply of young free plants to replace any that may show signs of exhaustion. Young plants planted this autumn should not, however, be cut, but should be allowed a season's growth to form themselves into good specimens.—J. C. B.

3262.—**Substitute for Grass.**—There are many plants that make excellent covers for margins and banks. Ivy is a good one, and needs only a little occasional trimming. The creeping Jenny is another that soon forms a dense cover of foliage. Perhaps the best for your purpose, however, would be the green Sedum Lydium, as this needs no trimming, except at the edges, and is always of a dense green carpet. Of creeping plants there is the Herniaria glabra, which becomes very dense, and forms a perfect mat of growth not more than 2 in. thick. It is a charming thing for the making of green carpets anywhere. We like also the Veronica repens, because that too is a dense creeping plant, and has the merit in the spring of being covered with tiny purplish-white cup-shaped flowers. It is then most lovely. All these are perfectly hardy, and any one good for the purpose.

3318.—**Furze Hedges.**—Good or bad Furze hedges are pretty much a question of attention. On light soils, if trimmed in close, there is no difficulty about it. There are several varieties, but for making hedges none are better than the common. The ground should be thoroughly cleaned and kept free from weeds. Plant in March moderate sized (not large) plants. Mulch over the roots, and water if necessary till the plants are established.—E. H.

3319.—**Fruit Trees.**—Plant Apples and Pears. If the clay is near the surface remove some of it, and put in good soil, or else raise the border by placing good soil over it. Plant as soon as the leaves fall. The following are a few good kinds : Apples—Early Julien, Stirling Castle, Manks Codlin, Cellini, Fearn's Pippin, King of Pippins, Court of Wick, Dutch Mignonne, Warner's King, Winter Pearmain. Pears—Williams' Bon Chrétien, Beurré Diel, Marie Louise, Beurré de Capiaumont, Pitmaston, Duchesse d'Angoulême, and Beurré Rance.

3283.—**Cucumber House.**—Build the flue in the centre of the space beneath the Cucumber bed ; the inner wall might be built on arches, the arches to be fitted with shutters to keep in or let out the heat at pleasure. The Cucumber bed may be supported with slates laid on a wood framework over the flue, but not touching it. On the slates should be placed leaves or dung ; on this again the soil. I have seen abundant crops of Cucumbers grown under such conditions. Of course a good deal depends upon the steady management of the fire.—E. H.

3331.—**Trees for Clay Soil in Devon.**—If the clay be well drained many kinds of trees will succeed inside a shelter of hardy trees, such as the Huntingdon Elm and the Abele Poplar, with an outer fringe of Willows. Among evergreens might be named the Yew tree and the Holly, the deciduous Cypress (Taxodium distichum), Cedrus Libani, Cupressus Lawsoniana, Juniperus chinensis, C. virginica (red Cedar), Picea lasiocarpa, P. Pinsapo, P. Nordmanniana, Thujopsis borealis, Evergreen Oak. Of deciduous trees some of the following may be planted : Eagle's-claw Maple, Acer rubrum, A tataricum, Ash (weeping), Beech (Fern-leaved), Birch (weeping), Catalpa, Thorns, Planes (American and Oriental), Oak (scarlet American), Poplar (Carolina), Tulip tree, Weeping Willow, Maiden-hair tree, Magnolia tripetala, and others.

3277.—**Violets not Flowering.**—We fear there is very little hope that your Violets will ever produce bloom ; they have probably become, like some Strawberry plants, quite barren, and should be destroyed. It is just possible that, by taking off and newly rooting the strongest of the runners, the plants would improve and flower, but it is really doubtful. It is now an excellent time to get plants and make a fresh plantation, and if obtained from some nurseryman, you may be assured that they will be of some good blooming strain. You will find the single blue Russian, the kind so largely grown for the London market, can be obtained cheaply, and the other best because the finest single kind is the Victoria Regina, a superb Violet. Of double sorts, Belle de Chatenay is a very fine new double white, but the old Queen of Violets is the purest colour. Blandyanum and the fine King of Violets are the best dark blues, and Neapolitan and Marie Louise the best pale blue

or mauve-coloured doubles. Plants of all of these if strong, put out now, should give a fine lot of bloom in the spring. All are very sweet, and though so simple and unpretentious, quite gems amongst early spring flowers.—A. D.

3330.—**Sea Sand for Plants.**—I give my experience of the use of sea sand for mixing with soil for plants in lieu of silver sand. I have used it constantly for over ten years, and never found it injurious. I tried it first for pricking out very tender Lobelias in. I used half sea sand and half leaf-mould. The plants flourished and made roots with wonderful rapidity. I found the little fresh fibres clinging to the sand, evidently enjoying it. I have used it for striking Myrtles, tender cuttings of Begonias, Fuchsias, and Geraniums with unvaried success. I mix it with soils for any description of plants. Calceolaria cuttings rejoice in it. In mixing for cuttings I pass it through a fine sieve; for rougher use I do not sift it too fine; the small pebbles tend to keep the soil open.—H. B. S.

3279.—**Plants for Hanging Baskets.** Evergreen subjects may consist of the Wandering Jew Saxifrage (Othonna crassifolia), and amongst Ferns there is nothing better than Woodwardia radicans. The variegated Cobæa also forms an excellent basket plant, growing into a dense curtain of beautifully marked foliage. Deciduous plants are to be found in the Moneywort and its golden variety, Siebold's variegated Stonecrop, and Fuchsia pendulaflora. Amongst flowering subjects may be mentioned the Nemophila, which should be sown early in the autumn, and the baskets filled by November. When thus treated, a fine display is obtained early in spring. Maurandia Barclayana, Lophospermum scandens, the Canary Creeper, and the varieties of Tropæolum Lobbi all make excellent subjects for this purpose. A very nice effect is obtained by placing a Fuchsia in the centre, finishing off with Petunias, Maurandias, and Tropæolums; or a hardy Fern of graceful habit, such as the Welsh Polypody, may form the centre, surrounding it with such plants as the creeping Toad Flax, Wandering Jew, Sedum carneum variegatum, and small pieces of the variegated Ivy. Such a basket will remain fresh and green throughout the winter.—B.

3255.—**Treatment of Arum Lilies.**—The cold summer of last year did not allow the Arums to mature their growth, the consequence being that flower-buds did not form. We remarked several patches of Arums last spring which showed scarcely any signs of flowering, simply owing to the fact that the temperature ranged too low during the growing season; for although this plant requires abundance of moisture, both atmospherical and at the root, when growing, it demands a rather high temperature to perfect its growth. The great point is to secure as long a season of growth as possible. The plants should be hardened off by the middle of June, and planted out in free rich soil, taking them up the first week in September. Your plants will probably bloom again next spring, as the past summer has been more favourable for them.—J. C.

3333.—**Propagating Pyracanthas.**—These are best increased by means of layers, bending down a young free shoot into the soil, cutting partly through at a joint and pegging it down. The operatian of layering is best performed at the fall of the leaf, when the young plant will be ready to take off the following autumn. Cuttings of this year's growth may also be inserted in a shady place. In pruning, cut out all small weakly shoots and lay in the strong ones at a fair distance apart. November is the best time to prune.—J. C.

3261.—**To Cultivate Bulbs in China Bowls.**—I find that the following plan succeeds admirably with Hyacinths: Place at the bottom of a large bowl several lumps of charcoal, then a layer of nice green Moss without soil. Place the bulbs on the Moss and cover well with more Moss; water about twice a week with tepid water. The bowl can be placed anywhere. The Moss requires light and any temperature, as you require the Hyacinths forward or late. I have tried this for years with success. I place the bulbs in a circle. Crocus bulbs I have not grown.—Woodlands.

3282.—**Cockscombs** succeed very well in a compost of sandy loam, leaf-mould, and some decayed cow manure, giving plenty of good drainage. Sow the seed in February or March in a temperature of 70° to 80°. When about 1 in. high pot off the seedlings singly into small pots, shifting them into larger pots in good time, never allowing the plants to get pot-bound. Keep the plants as near to the glass as possible. Give occasional waterings of diluted liquid manure, which will be found beneficial to them.—Kirkton.

3316.—**Lilium auratum.**—I bought a 1s. bulb in the City in the beginning of last year, and potted it in ordinary London mould with a good dash of silver sand and some rotten manure, and the result was one stem with six fair-sized flowers on it, strongly scented; and when the stem died in the autumn I cut it down to within 1 in. of the pot, and simply put the pot into a cold frame, with a flower-pot inverted down over the bulb. Early last spring I turned the bulb out of the pot, expecting to see that it had been killed by the frost; but, seeing the pot was full of root, I repotted it into a larger pot (about a 12 in.), filling the additional space round the bulb with some sifted mould mixed with silver sand and a sprinkling of Amies' Chemical Manure, and the result this season rather surprised me, for I had two stems, one with five and the other with four flowers, each measuring about 6 in. across when open. Considering that my plant has been grown entirely in the open air in the heart of the east end of London, I certainly think that there has been a want of attention on the part of "S. N.," and should advise him to try again, as I think it a plant very easily grown.—C. B.

Tree Fern (Dicksonia antarctica). See page 405.

3275.—**Grubs in a Greenhouse.**—We have of late been much troubled with grubs amidst a lot of young Cinerarias, and could not see the enemy in the daylight. The plants were for present convenience planted out in a soil bed, and were not in pots. Examining the plants by candle-light, we found the grubs eating the leaves, and thus caught them. Another examination the following night brought the same results, and thus we soon exterminated the entire batch of the troublesome insects. You should try the same plan. In any case they are more active by night than by day.

3265.—**Flowers for Spring.**—Pansies and Violas of the bedding section and in several colours, blue Forget-me-nots (Myosotis dissitiflora and sylvatica); Silene pendula, pink; double Daisies in several colours, double and single Primroses in many colours, Polyanthuses, purple Aubrietias, yellow Cheiranthus alpinus and yellow Alyssum, white Arabis and Iberis, white and pink creeping Phloxes, Omphalodes verna, Anemones in many colours, Saxifraga granulata, flowers double white; red and yellow Wallflowers, Queen Stocks, Limnanthes Douglasi, Saponaria calabrica, blue Nemophila. These are but a few out of what might be made a very long list of plants suitable for spring bedding and blooming. Of all these, however, are things that cannot now be dealt with from seed; in fact, the majority are increased by division of roots or by cuttings, and can now be had in plenty by purchase from florists who deal in these things. Of plants suitable for spring bedding or borders raised from seed are Silene pendula, Nemophila, Saponaria, Myosotis dissitiflora and sylvatica, Wallflowers, Stocks, &c. Seed of the Forget-me-nots should be sown early in July; Wallflowers and Stocks in May; Silene, Nemophila, and Saponaria in August. Pansies too may be raised from seed sown in July, but such plants cannot be relied upon to produce flowers of the colours indicated, though doubtless the larger portion will come true. Pansies and Violas obtained by propagation are far more valuable for spring decoration, because they give where wanted for massing entire evenness of height and colour.—A. D.

3260.—**Plants for Windows in Winter.**—Maiden-hair Ferns, yellow Cytisus, white Deutzias, Chinese Primroses, Cinerarias, Cyclamens, Camellias, early Azaleas, berried Solanums, Hyacinths, Tulips, and many other things will do well in the temperature of 40° to 50° if the air of the room is kept fresh and sweet; that is of the first importance to the welfare of all window plants. For earliest use some dwarf Pompone Chrysanthemums might be obtained, as they will make windows gay until nearly Christmas. Any plants kept in an open area would be of little service for a window except they were perfectly hardy, such as small shrubs, or Conifers, or border flowers like Primroses, Polyanthuses, Pansies, Iberis, Forget-me-nots, Alyssums, Daisies, &c.—A. D.

3316.—**Lilium auratum not Flowering.**—Excellent instructions on the growing of auratums have appeared more than once in Gardening. Many causes may account for their not blossoming freely. First in importance is to procure strong well-ripened bulbs, for here

lies the chief secret of success. The buds of the coming year are dormant in the bulb itself. Hence the vital importance of good bulbs. Plant as early as possible now in good turfy loam or peat loam and silver sand. Shelter the pots from frost as long as frost continues. Never expose your Lilies to a check from late frosts and cold winds. Shelter them from dripping rains, also from scorching sun. With moderate care you ought to have no great difficulty in getting plenty of blossom.—Lily Grower.

3314.—**Wireworms in Lily Bulbs.**—We are inclined to think that the wireworm is in the loam. If the bulbs are potted, put a spadeful of lime in a small tub of water, and then water them with the clear liquid. Repeat the operation twice, and the wireworm will in all probability die. When potting, take some white or river sand and mix with it some strong soot. Let this surround the bulb, and the wireworm will not approach it. We would try some in peat and leaf-mould, and see if there was any difference.—J. C.

2896.—**Best Time to Buy Hay & Grain.**—An experienced agriculturist states that no particular time can be given when the price of these articles is likely to be at the lowest. Those who wish to buy to advantage can only do so by watching the markets and purchasing when there is a drop. No one can tell, for instance, at present whether the price of hay will rise or fall this winter.

3282.—**Culture of Cockscombs.**—Cockscombs require the accommodation of a warm house or frame at the commencement of the year. They delight in strong heat, accompanied by a corresponding amount of atmospherical moisture. In years gone by, when the Cockscomb was held in such high esteem, it was generally grown along with early Cucumbers, both plants requiring the same conditions of growth. Growers then made a practice of sowing early in January, in free sandy soil, potting the young plants off when large enough into small pots and growing them along near the glass in the genial atmosphere of the Cucumber frame. It is necessary to sow thus early, as if sowing be deferred until a later period the plants, instead of forming combs, are very liable to run to leaf. The influence of the season causes them to make too strong a growth, whereas by bringing them along slowly at an early period the comb has time to form, and when the days get longer and light more intense the energies of the plant are concentrated upon the formation of the comb. The soil should be rich and free, consisting of loam, leaf-mould, and decomposed manure in equal parts. Although a hotbed is the best place, yet the Cockscomb may be grown in a light well-heated house.—J. C., *Byfleet.*

3321.—**Lily of the Valley.**—If it is Couch Grass that you have to contend with you had better take up the Lilies, thoroughly clean the ground, and plant afresh. Scarcely anything will grow where Couch has filled the soil with its underground stems. Take up the Lilies at once and lay them in carefully, then have the soil well and deeply stirred, extracting all the Couch. The ground should be gone over twice in order to make sure that none is left. Add a little manure to the soil and plant afresh.—C.

3322.—**Culture of Pyrus japonica.**—In order to induce this tree to make free growth, the soil around it should be stirred early in the year, and a good mulch of dung spread over the roots. When the weather is hot and dry, a good watering with liquid manure may be given. This treatment will promote the formation of strong wood, which, if fully exposed to the light, will give an abundance of bloom. Where it is seen that the wood is at all crowded the small weakly shoots should be thinned out, laying in the strongest branches at regular intervals, so that sun and air may play freely around them.—C. B.

3323.—**Hyacinths in Windows.**—Hyacinths may be potted at once, although the best way would be to pot a portion now, reserving the remainder until the middle of November, thus ensuring a succession of bloom. The Hyacinth likes a free, but rich soil—say loam, manure, and leaf-mould in equal proportions. Any free light garden soil will do, however, and if no thoroughly rotted manure is obtainable, add a little of Clay's Fertiliser or some concentrated manure to it. Pot so that the bulbs are covered with soil; water gently and cover the pots up with ashes or light soil in the open ground, allowing them to remain there until the latter end of November, when some of them may be brought into the dwelling. Covering up the bulbs with 2 in. or 3 in. of soil when first potted keeps them in their place, induces a more vigorous development, and causes the pots to fill with fibres before the bulbs themselves are subjected to the influence of artificial warmth, the effect of which is that from the moment that the flower-spike issues from the foliage it gathers strength from the large number of feeders contained in the soil. If, when the bulbs are taken out of the ashes, growth is appearing above ground, place a small flower-pot over each plant for a few days, gradually inuring to full exposure.—J. C. B.

3401.—**Gnat Bites.**—Ammonia is the best cure for gnat bites. When this is not procurable make a strong solution of soda and apply it to the parts bitten.—R. W.

3312.—**Pines in their Native Habitat.**—If by Pines J. Burford means Pine-apples, perhaps he may like to know that the most fragrant and luscious kind known in South America is found at Pernambuco, growing almost wild in sandy soil, and even sand, under the influence of a scorchingly hot sun. This variety is called Abacaxis.—Kensington.

3315. **Climbers for Covering Porch.**—We think that Ayrshire Roses would be likely to bloom fairly well in the situation mentioned. There is the golden variegated Honeysuckle (Pyrus japonica) and Cotoneaster microphylla, all of which would grow freely enough, and the Pyrus would give a certain amount of bloom.—J. C.

3257.—**Pruning Hardy Passion-flower.**—Do not touch the Passion-flower until next March, and then shorten back the shoots to three-fourths of their length. We should advise you to bring the shoots together before winter arrives, and tie a mat over them in severe weather, for this plant is liable to be killed off in hard winters.—B.

3311.—**Soil for Gum Flax.**—Do you not mean the Blue Gum (Eucalyptus globulus)? Keep the plants as they are in a cool greenhouse until March, and then pot them off. The Silver Leaf we do not know, but the young plants of this you had best treat in the same manner. The name we suppose to be a local one.—C.

3191.—**Pinus austriacus** is considered a good tree for seaside planting.—J. H.

3263.—**Rhubarb** can be transplanted any time in the autumn; the present would be a good time.—Kirkton.

3326.—**Cinerarias Failing.**—We can only surmise that you have given too much water at the root, thereby causing the fibres to perish. Perhaps the soil employed is too heavy. The Cineraria likes a free, fairly rich mould, a compost consisting of equal parts loam, leaf-mould, and well-decomposed manure best suiting it. After potting, keep the plants in a cool situation, watering for a time with great care.

3327.—**Roses for Arches.**—Gloire de Dijon is a very good Rose for the purpose, with which may be associated Aimée Vibert, Charles Lawson, and Cheshunt Hybrid.—C.

3328.—**Climbers for North Aspect.**—Nothing would give more satisfaction in such a situation than green and variegated Ivies, such as the large clouded white, the small-leaved variegated, and the common Irish. The evergreen Roses would also be likely to do fairly well, and you might try Pyrus japonica and Cotoneaster microphylla.—J. C. B.

3325.—**Name of Rose.**—If "H. J. P." will correspond with me, I think I can easily obtain the name of the Rose growing on the wall of La Villa Doria through a relative of mine living at Genoa. My address is—Leonard Hannan, *Prospect Hill, Howard's Field, New Catton, Norwich.*

3290.—**Gentians not Flowering.**—The Gentiana acaulis loves a slope, such as it finds on its native mountain sides; if the soil is too rich it will not flower. It should have turf mould, with sand and some stones stuck between the plants; a well-drained bank, where it will not be parched up. A cheerful and partially sunny aspect will suit it best.—S. F. M. L.

3283.—**Flue in Cucumber House.**—Let the flue be made in the centre of the border, then fill up between it and the front wall with brickbats to about 6 in. above the flue; then fill up with a mixture of good turf, sandy loam, and well-rotted manure.—T. S. W. S.

3252.—**Spring and Autumn Flowering Shrub.** The old pink China Rose not only flowers in spring and autumn, but all the summer. The Daphne Mezereum (Mezereon) flowers beautifully in early spring, and is very gay with scarlet fruit in autumn. The Cratægus pyracantha flowers in spring, and is covered with its beautiful fruit in autumn. Standard plants are very effective. Others might be mentioned if one could stop to think.—E. H.

3268.—**Outdoor Vines.**—Plant the following: Black Cluster, Miller's Burgundy, Early Summer, Frontignan, and Early White Malvasia. Any one having a good wall with a south aspect to spare will be doing public service by collecting into one place all the earliest hardiest Grapes, and thoroughly testing them.—E. H.

3281.—**Plants for Shady Wall and Roof of Conservatory.**—Plant Camellias and Myrtles for back wall. A Lapageria would doubtless grow, but I am doubtful about its flowering well till it reaches the roof.—E. H.

3264.—**Unfruitful Fruit Trees.**—A heavy dressing of clay will be the best thing to apply. Lay it on as soon as the leaves fall. Leave it exposed on the surface a couple of months, then fork it lightly in. It will give substance and body to the light brashy soil.—E. H.

3259.—**Wintering Roses in the West Riding of Yorkshire.**—Have them all on their own roots. The Teas could then be carefully lifted and laid in some dry spot thickly where protection can easily be applied. The H.P. and others can be sheltered with branches or dry Fern after the winter sets in. In this way scarcely a plant will be lost.—E. H.

3258.—**Slimy Growth on Lawns.**—It is an Algæ of some kind, perhaps the Witch's Butter (Nostoc commune) or some of that family. I have destroyed it on gravel paths by using salt. A mixture of lime and soot will be useful on Grass lawns. To have it is troublesome; apply it in spring.—E. H.

3278.—**Saving Aster Seed.**—In dealing solely with Asters it is well to mention that all kinds do not seed freely. The fine double Victorias, the large Pæony-flowered, and other flat-petalled kinds are not free to seed, and in this country if the autumn is damp very liable to rot in the stem. On the other hand, inferior kinds and all the quilled Asters seed freely, and the latter reproduce well the finest strains. Directions are given in a previous answer.—A. D.

3259.—**Wintering Roses in the West Riding of Yorkshire.**—During ordinary winters the standard and dwarf plants of the Hybrid Perpetual class will not be injured if a munificent mulching of manure be given at the beginning of December. This will protect the roots from the ravages of frost, and the trees will be quite safe. The Teas and Noisettes should be taken up towards the end of October, laid in and protected by a cold frame, and replanted in April. If the weather is very severe, Fern leaves, branches of Laurel, &c., placed amongst the growth of Roses out-of-doors will give some protection.—William Walters, *Burton-on-Trent.*

3356.—**Catching Slugs.**—Procure from a brewery some lees, which will be given gratis. Place them on a tile or piece of slate near the part affected by slugs; they will collect in large numbers during the night. Overturn the tile in the morning, kill the slugs, and prepare afresh for the next night.—G. G. R.

3415.—**Wintering Plants.**—*Margaret.*—The Delphiniums are hardy, so are the Columbines, and probably the Tropæolums, but we cannot say unless we know what kinds they consist of. As you say the above plants are in pots, plant them all out into deep sandy soil; they will do no good in pots. Send us a bit of the Tropæolum and we will tell you if it is hardy.

3416.—**Apple Trees Flowering.**—*Ferndale.*—This frequently occurs at this time of the year when a sunny summer follows a dull one. The trees will suffer no injury.

3417.—**Planting a Garden.**—I shall be thankful for advice on the planting of two long beds, running each side of a wide gravel walk opposite drawing-room window. The beds are 5½ ft. by 60 ft. on turf, and run east and west; soil heavy clay. I wish for a bright floriferous mixture of bedding out, herbaceous, and bulbous plants, and think that it should be partly formed to suit the broad straight walk.—F. N., *Somersetshire.* [You cannot do better than select from the list given in Gardening, Oct. 9. The colours and height are given, and you can make a selection according to your taste. We shall shortly publish a list of hardy bulbs, and likewise a list of plants which require annual or biennial division.]

3418.—**Thinning Camellia Buds.**—Is it advisable to thin out Camellia buds now? In many instances three or four buds crowd each other.—Ch. Andrews. [Yes; do not leave more than two together.]

3419.—**Planting Ivy and Virginian Creeper.**—When is the best time to plant Virginian Creeper? Does it want much manure? and would it succeed well in a very windy situation along with Ivy on the front of a house facing S.S.E? Also what is the best kind of Virginian Creeper to plant? and is it a self-clinging plant?—Hallamshire. [Plant now or in spring in well-manured, deep soil. If you want a close-growing plant, get Veitch's Virginian Creeper (Ampelopsis Veitchi), but if you want a more rampant grower get A. hederacea. It will thrive in nearly any situation. It will not support itself in a windy situation, but Veitch's kind will cling to the wall like Ivy.]

3420.—**Brown Spots on Rose Leaves.**—*T. W. W.*—You must expect Rose leaves to be getting brown at this time of the year.

3421.—**Lophospermum scandens.**—*T. W. W.*—It will be all right in any ordinary greenhouse. If it is planted outside cover its roots with a few inches of ashes and a little dry Fern or similar covering.

3422.—**Planting Evergreens.**—When is the time to plant Hollies and other evergreens in a windy and bleak situation? Is manure needful or beneficial?—Hallamshire. [Now is the time to plant. Trench the ground 2 ft. deep at least, and give a good dressing of well-rotted farmyard manure.]

3423.—**Devil's Apple.**—Newspaper reports of a recent inquest held by Mr. Carttar, at Deptford, stated that Dr. Speed said he was unable to account for death until he examined the intestines, in which he found some black particles and a seed of what was known as Stramonium or Devil's Apple, a wild berry and a deadly poison. The verdict was "Accidentally poisoned by eating wild berries." Can you inform me what plant is referred to?—W. Macmillan. [Mandragora officinalis, commonly called Mandrake, is the Devil's Apple. Stramonium is the Thorn Apple (Datura stramonium), a common plant in hedgerows, the fruit of which is deadly poison.]

3424.—**Evergreens Eaten by Insects.**—*S. A. C.*—It is a green caterpillar that has eaten the leaves. Hand-picking is your only remedy.

3425.—**Wintering Feverfew.**—*R. G.*—The Feverfew is perfectly hardy, but is best raised from seed every year.

3426.—**Propagating Virginia Creeper.**—I have a very pretty Virginia Creeper which clings to the wall most tenaciously by little rootlets. Being anxious to give some of it to a friend, I should be glad to know if this would be the proper time, and how ought I to set about it?—Pansy. [You may take off some of the shoots a few inches long having little rootlets, and pot them round the edge of a pot in sandy soil, and place them in a frame or under a handlight, but they would strike best in spring just as growth commences.]

3427.—**Manuring a Garden.**—Part of my garden is composed of soil inclined to be heavy, and the other part a rich brown, but shallow loam. It has this season grown a moderate crop of Potatoes, &c. I have it now partly in Celery and partly in Savoys, and have dressed it well between the rows with lime. I want to grow Beans, Peas, Celery, and Potatoes next spring. Shall I

have to use more manure when planting and sowing or not? I gave a liberal supply last spring.—HALLAMSHIRE. [Yes; well manure it and dig it up now, and let it have the benefit of the winter. Put Broad Beans, Cabbages, Broccoli, &c., in the stiff soil, and Peas, French Beans, Celery, &c., in the brown loam.]

3428.—**Lilacs not Flowering.**—I have two Lilac trees which do not bloom, and the foliage is extremely poor. They are planted in a corner against a wall. Can I remove them now? and what is the best treatment to improve the foliage and induce them to bloom? I may mention that round about the roots are a great number of twigs; should these be removed? [Move them now and plant in well manured soil in a sunny situation. Cut off all the suckers and thin out weak shoots from the heads.]

3429.—**Roses from Cuttings.**—*C. C.*—Much information has been given on this subject both in the first and present volumes of GARDENING.

3430.—**Camellias Blooming Early.**—What is the reason of my Camellia flowering so early? It was potted after making its new growth, and in June it was plunged in a bed of coal ashes under a north wall, where it remained till the beginning of September. It was then bursting its first bud. I removed it to a coal pit to shelter it from the heavy rains, and it has been in constant bloom since, and will last, I think, up till the end of this year.—J. H. [It made early growth which ripened early in consequence of being placed out-of-doors so soon after growth was completed. There is, of course, nothing remarkable in Camellias blooming in October. Indeed, they are plentiful in the market early in September.]

3431.—**Vegetable Marrows.**—I have some Marrows that (until the rains came) were doing well, but they have little green spots come along their upper surface. They are nearly full size. I should be glad for advice in the matter.—E. A. [Cold and damp are no doubt the cause.]

3432.—**Insects on Vine Leaves.**—*A. J. A.*—Red spider caused by a dry, hot atmosphere and insufficient ventilation. When the leaves come off the Vines, prune them and well scrub the rods with soap and water, whitewash the house, and next year ventilate more freely, and keep the paths and borders moist during hot weather.]

3433.—**Tenant's Right to Trees, &c.**—Two years since I took a house, belonging to which there was a piece of ground, or garden not cultivated. I planted same with shrubs and fruit bushes. I have now given notice to leave next March; cannot I remove the shrubs and fruit bushes?—A CONSTANT READER. [Not legally. You may make some arrangement with the landlord or incoming tenant.]

3434.—**Hyacinths in Glass.**—*Languey.*—See GARDENING, October 16. Hyacinths in pots may be watered after being potted, but they must be placed outside to dry for a few hours before being buried in ashes or put in a closet or cupboard.

3435.—**Grafting Plum Trees.**—How am I to proceed with some Plum trees which were raised five years ago from the stones? They are now about 6 ft. high, and the stem 3 in. in circumference; they have never blossomed. Is it necessary that they should be grafted.—A. M. G. [They may be grafted with some free fruiting Plums, such as the Victoria or Early Rivers. Your best plan would be to get the services of a good gardener for a few hours, who would doubtless give you a few grafts and do the work for you. If you graft them yourself you will probably fail unless you have some experience in the matter.]

3436.—**Benzoline and Plants.**—I have a greenhouse, in which during the night I burn a small benzoline lamp. The lamp does not smoke, but the greenhouse smells very strongly of benzoline. Is this injurious to plants such as Geraniums, Fuchsias, bulbs and also Maiden-hair Ferns? If so, how can I remedy it?—POSE. [The fumes of mineral oil are very injurious to plants. Your only remedy is to get one of the stoves which are specially constructed to be heated by paraffin oil or benzoline, and carry off the fumes by means of a small chimney. Such stoves, especially those that are made of terra-cotta, are very efficient and lasting.]

3437.—**Apricot Suckers.**—*A. S.*—If the trees you speak of are merely suckers from an old tree they will never flower nor bear fruit, as they are not Apricots at all, but suckers from the stock on which the trees were grafted. You may try grafting or budding them with the Moorpark Apricot.

3438.—**Warts on Apple Trees.**—*A. S.*—The white matter which causes the warts on the Apple trees is, no doubt, American blight. Well paint the parts with paraffin oil.

3439.—**Stapelia.**—*A. S.*—This belongs to a genus of Asclepiadaceæ, natives of the Cape of Good Hope.

3440.—**Manuring a Garden.**—*F. G. R.*—During the winter months is the best time for this operation unless artificial manure is used. That must be used when the crops are put in.

3441.—**Wintering Verbenas.**—*Practical Gardener.*—These may be wintered in a cold frame if a good covering be applied during frosty weather. Plenty of air must be given during fine weather, or mildew will soon destroy the plants.

3442.—**Wintering Gloxinia Bulbs.**—*Practical Gardener.*—A temperature of 55° to 60° will not be too high for these. Keep them dry and they will take no harm.

3443.—**Heavy Pear.**—I have just weighed a Duchesse d'Angoulême Pear from a wall in my garden here at Slough, and it turns the scale at 1 lb. 2 oz; another from the same tree weighs 11 oz. I have before had one of ¾ lb., but cannot hear of an English Duchess weighing 18 oz.—R. H. B. [We have seen fruit of the Pitmaston Duchess, which is a similar kind to the one named, weigh 2 lb.]

3444.—**Violets.**—I have just planted in a frame for winter blooming Violet plants taken from the open border. They were put in the border last spring when young plants, and they have grown very large and strong, and have thrown outside runners. Ought I to take off these runners now, my object being to get as much bloom as possible this winter?—HEATHER. [Yes; take off the runners and plant them in a frame, or out-of-doors close together.]

3445.—**Herbs in Winter.**—Will roots of Hyssop, Rue, Horehound, Wormwood, Balm, Sage, and Lavender stand the winter? or will they have to be taken up?—J. C. [They are hardy.]

3446.—**Winter Plants.**—Should Fuchsias, Geraniums, Petunias, and Ice plants, which were sown in March, be still kept growing on or not?—J. C. [No; keep them clean and healthy, and in a temperature just sufficient to keep them in good health.]

3447.—**Red Spider in Vinery.**—Please inform me the cause of red spider in a small greenhouse among the Grapes and the cure.—E. B. [A hot, dry temperature; insufficient air. Well syringe or sponge the leaves with soap and water, and keep a moister atmosphere next year. The spider will not prosper much now.]

3448.—**Worms in Garden.**—*B. T., Lancashire.*—Apply a good dressing of salt, soot, and lime, and well work it into the soil, ultimately throwing it into ridge to remain through the winter.

3449.—**Woodlice in Dairy.**—My dairy is infested with woodlice; can you inform me how to get rid of them?—A. A. [Fill some small flower-pots lightly with dry hay, and place them bottom upwards about the dairy, just tilting the pots sufficient to allow the insects to get underneath. Examine the pots every morning, and turn their contents into a bucket of hot water.]

3450.—**Moss on Lawns.**—Within the last few weeks my lawn has become covered with Moss; how can I get rid of it?—MOSS. [Rake it up with an iron-toothed rake, well sweep the lawn with a stiff birch broom, then sow it with wood ashes and soot. In March sow some lawn Grass seed.]

3451.—**Keeping Caladium Bulbs.**—*G. V.*—These are best left in the pots if room can be spared for them. Place them in a warm, dry corner, and sprinkle them with the syringe occasionally. Dry them off now gradually, not suddenly.]

3452.—**Manuring Fruit Trees.**—Will you give me information as to the manuring wall fruit trees? when and how often manure should be applied, especially in the case of Pear trees and Plum trees?—BETA. [Apply a coating of manure early in summer when the trees have gone out of bloom. Let it lie on the surface till autumn, when the leaves have dropped, and then carefully prick it into the soil with a fork. If the trees are vigorous, however, and make much growth at the expense of fruit, manuring would be injurious rather than beneficial.]

3453.—**Striking Geranium Cuttings.**—Will Geranium cuttings root now? and if so, what is the best treatment for them?—ERIN. [It is too late now, but you may try a few in pots of sandy soil in a warm frame, greenhouse, or window.]

3454.—**Planting Wistarias.**—*West Town.*—Plant now or in March.

3455.—**Crimson-leaved Bedding Plant.**—Can you tell me the name of that small crimson-leaved plant something like a Coleus, which is so much used for carpet bedding in the parks of London and Paris?—ARTHUR. [If very small leaves it is Alternanthera, probably, but Iresines bear some comparison to Coleuses.]

3456.—**Lime Water in Soil.**—If lime water be freely used upon a flower border for the purpose of killing worms and insects, is it injurious to plants or cuttings? and does it injuriously affect or improve the fertility of the soil?—T. H. [If applied without wetting the plants the lime water will destroy the worms and slightly improve the soil if not given in too large quantities.]

3457. **Sedum Sieboldi.**—I have a plant of Siebold's Stonecrop (Sedum Sieboldi); it has shown flower-buds, but they have never advanced. What am I to do to make it flower? It is in a basket hanging from roof; not often watered.—ERIN. [Probably it wants more air and sun.]

French Beans Ill-shaped.—*W., Dulwich.*—Imperfect fertilisation of the flowers probably.

Laying out a Garden.—*Ignoramus.*—No one can tell you how to lay out a garden without seeing it or a plan of it.

Greenhouse Pests.—*A Subscriber.*—We will attend to your queries in due time.

Inquiry.—Duke of Argyle's Tea Tree (Lycium barbarum).

A New Hand.—We cannot help you unless you send us your name and address.

Climbing Carnations.—*Nemo.*—You mean what are known as Tree Carnations. You can get a collection from any good plant nursery.

Pots for Hanging against a Wall.—*J. Knight.*—You can no doubt get them at any pottery.

Garden Annual and Directory.—*G. W. W.* 37, Southampton Street, Covent Garden.

Arum Lilies.—*Amateur.*—The treatment of these has been given several times in GARDENING recently.

Lamium striatum.—*Kathleen.*—At any of the large hardy plant nurseries, such as Ware's, Parker's, Backhouse's, &c.

Carnations and Picotees.—*Author.*—See our advertising columns; we cannot recommend tradesmen.

O. G. K. Y., Manington.—Send us your address and stamped envelope and we will advise you.

Rusticus.—Apply to Messrs. Jackman & Sons, The Nurseries, Woking.

Hamburgh.—At any of the fruit tree nurseries.

Scarborough Lily.—*W. H.*—See GARDENING, Oct. 2, of this year.

Names of Plants.—*B. H. W., Twickenham.*—1, Blenheim Orange; 2, New Hawthornden; 3, Cox's Orange Pippin; 4, Golden Harvey.——*Henry Meers.*—Send us flowers and leaves.——*C. Fuller.*—1, uncertain; 2, Golden Pippin; 3, fine crowned Pippin.——*W. K. L.*—We cannot name Violas or Pansies.——*Fiz.*—We cannot name Roses, and especially from decayed blossoms.——*F. N.*—Viola pedata.——*East Sheen.*—King of the Pippins.——*E. M.*—We cannot name the plant from a mere leaf; send us a good shoot and we may be able to tell you its name.——*J., Oldham.*—Datura stramonium, a weed in hedges, and deadly poison; it is not worth culture.——*A. J. B.*—Fuchsia fulgens.——*G. M. Hinton.* We cannot name nor advise on the culture of a plant from seeing a paltry little leaf; send us a good shoot.——*Shepherd's Bush.*—Holly Fern (Aspidium Lonchitis), a common kind.——*L. J.*—1, Adiantum Luddemannianum; 2, Polypodium pleisorum; 3, Adiantum assimile; 4, Polypodium glaucophyllum; 8, Adiantum hispidulum; 9, A. Henslovianum.—*Ignoramus.*—Agrostemma coronaria.——*Bath.*—Felicia capensis.——*R. A. G.*—Asplenium Fabianum.——*F. B. J.*—1, Salvia of some sort; 2, Santolina incana; 3, Sedum spectabilis; 4, S. oppositifolium; 5, Saxifrage (species).——*A. P., Stretford.*—A worthless Solanum.—*Ashtead.*—Plumbago Larpentæ.——*R. H. O. S.*—1, Sedum oppositifolium; 2, S. populifolium; 3, S. anacampseros; 4, S. telephium (variety); 5, S. Sieboldi.——*T. L. W.*—Erica Massonii.—*A. R. C.*—1, Mentha gibraltarica; 2, Sedum acre; 3, Coprosma Baueriana variegatus; 4, Euonymus japonicus maculatus; 5, E. radicans variegata.——*Jas. Tyler.*—Seed vessels of the common Honesty (Lunaria biennis).——*R. J. Thompson.*—Nephrolepis exaltata.

QUERIES.

3458.—**Quick-growing Trees and Shrubs.**—I shall be much obliged for advice as to what trees and shrubs of quick growth I can plant at the bottom of my front lawn, to screen from the road and form a thick hedge to shut out some unsightly cottages opposite; also the names of ornamental trees and shrubs suitable for the lawn of rapid growth. Aspect N.E. Country place.—HELENA.

3459.—**Pyracantha not Flowering.**—Can any one suggest what should be done with a Pyracantha that has not blossomed since the frost of 1878? The foliage is scanty, and it is not thriving. It grows against a wall.—SUNFLOWER.

3460.—**Climbers for Porch and House.**—The back of my house faces slightly west of north; fully exposed to that aspect; the subsoil is clay, well drained, and we have at times cold night mists from a valley. What climbing plants would best succeed against the house wall, and also for covering a wood trellis-work porch? From the front of the porch a narrow border, about 2 ft. wide, runs with a curve past the windows round the end wall of the house to the side entrance. What flowers will grow in this border, both at the back and west side? The boundary fence and some trees are 15 ft. from end wall. The eaves of the house project considerably.—P. Q. R.

3461.—**Shrubs for Screens.**—I have next to my garden a vacant plot of land which slopes to a public road, so that passers by can see the whole plot over the boundary fence. Sixty feet from the road are two fine Oak trees. Ten feet in front and south of these I want to plant a row or belt of shrubs to grow 8 ft. or 10 ft. to shut out the rest of the land from observation. Around the trunk of, and 10 ft. or 12 ft. from the larger Oak, I want a complete circle of shrub, excepting the inlet to what is desired to be a shady nook with rustic seat. What shrubs will be best for my purpose? I shall have to make up the soil for the plants in front of the trees, as the loam has been removed, leaving only a cold clay. There is good drainage.—EVERGREEN.

3462.—**Dendrobiums not Flowering.**—I have three fine plants of Dendrobium nobile which flowered very badly last season. I shall be glad if any one will inform me how to treat them, and when is the best time to repot? I have a Vinery and stove heat at command.—G. V.

3463.—**Culture of Oleanders.**—Will any reader inform me what is the best soil, and give me other directions for cultivating Oleanders?—IGNORATIO.

3464.—**Violets by Post.**—Can any one tell me where tin boxes can be got for this purpose?—JANE H.

3465.—**Evergreens for Chalky Soil.**—Can any reader tell me what evergreen trees will flourish on a chalky soil? They are wanted to form a screen.—CANON.

3466.—**Improving Lawn.**—My front lawn is in a dreadful weedy state, and I am most anxious to have it look like a lawn. When is the best time to hand-pick the Daisies? and can I destroy the Dandelions? The Grass is very coarse and rank, though it has had frequent rolling and cutting with machine. Would manuring do it any good? When should it be done? and how long would it require to be on the Grass?—A. M. K.

3467.—**Trellises for Screens.**—I am about to form a new border for hardy flowers next to a walk which divides the kitchen from flower garden. At the back of the border I think of erecting a line of trellis-work about 5 ft. or 6 ft. high, on which to grow Honeysuckle, Roses, Clematis, &c. The trellis would face south, and behind it and so near it, that their branches would almost touch the trellis, would be a row of pyramid Apple and Pear trees. Would the trellis and creepers so shade as to injuriously affect the fruit trees, &c.? If so, can any one suggest what I could better use at the back of the flower border as a divisional line? I cannot well move the fruit trees.—P. Q. R.

3468.—**Law Respecting Greenhouses.**—What are we (the readers of GARDENING ILLUSTRATED) to understand by "The Law Respecting Greenhouses," page 359, September 25? Here are two opinions—one magistrate says they are exempt, and mulcts the man out of 30s. for being in the right. The other says such buildings are not exempt, and he has had to put in brickwork up to the sashes. Taking the two opinions, it would seem as if they (the officers or magistrates) would debar an honest, hard-working, industrious man from anything in the way of amusement. The question naturally arises, Will such buildings become rateable to the poor, highways, sanitary, &c.? It would be well if the law on the subject could be clearly stated.—R. K. A.

3469.—**Wintering Ranunculuses.**—I am told there is great difficulty in preserving Ranunculus bulbs through the winter. Will any one tell me the best way to save them?—W. S.

3470.—**Worms in Cinerarias.**—I lately received some Cineraria plants, but not being able to pot them for two days they drooped, and looking at the plants a day or two after potting day, I found some small white worms and a lot of other insects under the pots. Can any one give me information as to how to proceed?—AMATEUR.

3471.—**Dandelions on Lawns.**—I should be glad to know what is the best way to eradicate Dandelions from lawns. The roots penetrate so deeply, that they cannot be effectually removed with a spud. Will constantly cutting the crowns cause the roots to rot away? Does Watson's lawn sand really kill the roots?—E. E. W.

3472.—**Portable Flower Boxes.**—Can any reader inform me where can be procured the Albert Vase Flower Box recommended in Beeton's "Young Englishwoman" ten or twelve years ago? The vases could be used separately for flower-pots, or fitted together for window boxes. —E. S.

3473.—**Blue Hydrangea.**—Is it true that Hydrangea cyonoclada is a constant blue? it is so advertised. Perhaps some of your readers would let me know before I purchase, as I am rather sceptical about it—S. L. Bourchier.

3474.—**Insects in Pansies.**—About the commencement of the year I bought some rooted cuttings of Pansies. For some time they got on very well, but after a while they seemed to be dying off. On taking away a little of the earth around the stalks, I found very small white insects, very like the mites we see in cheese, which were gradually eating the stalks of the plants What are they? and can the evil be remedied?—Creditonia.

3475.—**Rose on West Wall.**—Would a Niphetos Rose do well on a west wall? if not, what one would?—Creditonia.

3476.—**Buds Dropping off Camellias.**—Can any reader give any information of the cause of flower-buds dropping from two large Camellias? They have never been allowed to get dry. Two others by the side of them getting similar treatment are doing well and retaining their buds; the plants are about 8. ft. high and covered with buds, but getting a little black on top of bud and dropping off.—R. Templeton.

3477.—**Xanthoceras sorbifolium.**—I have a small plant of this which I ordered from a nursery last spring. I expected to get a fair sized shrub, but received a small plant in a pot. I planted it in a shrubbery border, and though its leaves are green and fresh it has made no growth. It is about 6 in. high and is in a sheltered place, but my subsoil is heavy clay, and position cold in winter. Would it be best to pot up my young shrub for winter, or let it remain in the border?.—Evergreen.

3478.—**Stones for Rock Plants.**—I have one side of a long low bank made up with large stones, and planted with rockery plants—Sedums, Sempervivums, mossy Saxifrages, dwarf Phloxes, &c. Many of the stones (refuse from mines) contain minerals, iron and lead ore, mundic, &c. Will these stones be too cold in winter for the plants, or otherwise injurious? The plants root into a good depth of good loam.—P. Q. R.

3479.—**Winter Cucumbers.**—I have a greenhouse 10 ft. by 8 ft., heated by hot-water pipes. I am desirous of growing Cucumbers this winter along with my Geraniums, Coleus, &c. Could any friend give me any information concerning it?—H. H. Statham.

3480.—**Climbers for a Greenhouse.**—I want two climbers for a lean-to greenhouse, about 14 ft. by 12 ft., temperature in winter about 55° to 60°, one to flower the last three or four months of the year, and one to flower the first three or four months of the year. The flowers must be white, freely produced, scented if possible, and good for cutting, not over difficult to cultivate, and if they do not require peat to grow in so much the better; lastly, they must be clean. If any practical reader would answer this, I shall be much obliged.—S. L. B.

3481.—**Neapolitan Violets.**—Will some one kindly tell me the proper treatment for the Neapolitan Violet grown in pots? and what soil should be used?—M. A. Y.

3482.—**Plants for Conservatory.**—I propose building a half-span greenhouse or conservatory about 15 ft. by 20 ft. area, south aspect, to be heated by a tubular boiler. I am unable to scheme out the best arrangement having regard to the greatest usefulness. Some plants I find must be kept just clear of frost, others at temperatures ranging from 40° to 70°; some a cool, dry atmosphere, others a hot and moist one. No doubt a great many of your readers, besides myself, would be glad to have a general description of a house adapted to the greatest variety of purpose and the methods of working it; also the most useful temperature to provide for; what length of 4-in. pipe per cubic foot of space, and what plants it would be adapted for? also if I partitioned off a portion of the house, what increased advantages would this procure me? I should also like to know whether two lengths of 4-in. pipe passing through a pit or bed would produce that bottom heat which is so often referred to.—Mole.

3483.—**Bare Places on Bowling Green.**—What can I do with a bowling green on which some places are very bare? Can anything be applied now to make the Grass grow? What is the best manure to apply in spring in a liquid state?—A. G.

3484.—**Treatment of Old Fig Tree.**—I shall be obliged if any practical gardener would inform me how to prune and treat a Fig tree which has grown luxuriantly for twenty years on a wall facing south, but does not bear fruit. Signs of fruit have appeared in spring, but the Figs have always dropped off when quite small. —E. P.

3485.—**Climbers for House.**—Will any reader kindly inform me what are the best evergreen creepers to place on the south-east side of a red brick house?—G. J. H. P.

3486.—**Plants for Pillars.**—I have a pillar in my greenhouse 6 in. round and 14 ft. high. I want to cover it with a rapidly growing effective climber; what would be the best? and should it be grown in a pot? or should a tile or two be removed to plant it out? There is a border in the house 16 in. in width and about 12 in. in depth; what can I put in it now? The house is well heated with hot water.—Constant Reader.

3487.—**Fruit Trees for London.**—Will someone kindly inform me which are the best six varieties of dessert Apples, six varieties of kitchen Apples, six varieties of dessert Pears, and six varieties of Plums suitable for cultivation near London?—An Enquirer.

3488.—**Fruit Trees for Monmouthshire.**—Will any reader tell me what Apples, Pears, and Cherry trees are likely to do well in the neighbourhood of Trelleck, Monmouthshire, which is about 600 ft. above sea level? Will Vines, Raspberries, and Strawberries succeed there? —Devaudon.

3489.—**Keeping Plants from Drying up.**—I have a greenhouse heated by a brick flue. In winter when I have much fire the plants become dried up. I am told to make a trough on top of the brickwork near the fire, but I think the steam from the water would injure soft-wooded plants. Will some reader suggest some means of remedying the evil.—W. P.

POULTRY.

Feeding Poultry.—In feeding fowls make it a rule to give them their meals as nearly as possible at the same hour each day. It is a bad habit to give them food at irregular times; they get into the way of expecting it whenever they see you, and besides being disagreeable it is not good for the birds. Usually, full-grown fowls in confinement are over-fed, especially as regards grain. Two good meals a day with the addition of the house scraps are sufficient for laying hens, for a fat hen never lays well. With chickens it is different; from the second to the fifth month they require very high feeding; a check in their growth can hardly ever be made up afterwards. The first meal in the day should be of soft food. Coarse oatmeal, or, better still, Oats ground with the husk should be worked into a paste with butter-milk or boiling water and makes very good food. Once or twice a week part pollard or boiled Potatoes may be used with the oatmeal. The greater variety of food, provided it is suitable, the better for fowls that are shut up. Spratt's Poultry Meal used in the same way is safe and wholesome, and the fowls are very fond of it. In mixing any kind of meal be careful not to make it too wet; it should be a light crumbly mass, and if it is sticky and adheres to the fingers when kneading it, you may be sure it is too moist. Fowls are such bad gardeners, that it is often difficult to let them have any liberty, but where it is possible to turn them loose upon a small grass plot it is very beneficial to do this in the morning before their first meal. If only for ten minutes it gives them an appetite, and makes a great difference to their health and laying. See that the vessel in which the soft food is given to them is scrupulously clean and scalded once every day. Let them have as much as they will eat greedily; as soon as they begin to pick and leave it take it away at once. Between this and their second meal, which should be given some time in the afternoon, let them have as much green stuff as they will eat —Cabbage, Lettuce, Beet leaves, and Grass cuttings. If fowls cannot have a Grass run they must be supplied with cut Grass as often as possible; the flavour of the eggs and deep colour of the yolk greatly depend on this, and the plumage of the birds cannot be kept bright and glossy without it. All the scraps from the kitchen should be collected for the fowls' use. In a large family this amounts to a great deal, and instead of being thrown in the dust bin and creating bad smells or put on the kitchen fire, and poisoning the house with an equally disagreeable, though not so unwholesome, smell, if given to the fowls it will make a great difference in the cost of their keep. Potato parings, Pea shells, ends of Beet, Carrot, and Turnip should be boiled and thoroughly drained before giving to them, and the pail in which the scraps are collected must be kept perfectly clean, and the contents emptied into the fowls' run once a day. Whatever is left uneaten next morning should be swept up, together with Cabbage stalks, and buried in some corner of the garden kept for the purpose. The corn used for fowls should be good sound Barley. It is a great mistake to give inferior or damaged grain; in the long run the best will be found to be the cheapest. Some people use Rice, and a great deal is sold in the shops under the name of "chicks' rice." It never pays to use it; there is hardly any nourishment or egg-producing property in it, and for young chicks is positively harmful. It may be used occasionally as a change of food if the fowls have been over stimulated with using some of the highly spiced patent meals, and it is beneficial in cases of diarrhœa, but to give it constantly in place of Barley is a mistake. Dari is excellent grain for fowls, but it is difficult to obtain in England. M. A. C.

Feeding Poultry.—"B. J. C." should not feed hens on Maize; it is too fattening. A little Spratt's Poultry Meal soaked over night in hot water and mixed with a little good sharps (with Barley meal and sharps now and again for a change) for the morning meal, and some good English Barley (whole) given for the afternoon meal (as much as the hens can eat), will be the best plan to keep laying hens. A change every three or four days in the food is very good, and warm breakfasts are beneficial.—Poultry Maid.

Vermin in Geese.—I am making a collection of parasites, and should like to have some of the vermin mentioned by "Lupus" under this heading.—L. G.

Poland Fowls.—In answer to "Cymro," Mr Hewish, of Nursery Lane (or Road), Brixton, Surrey, supplied me with a pen of Gold Polands last year, and they fully bore out the name they have of being everlasting layers, the average of three pullets being 205 eggs. —Gold Poland.

BEES.

Keeping Bees through the Winter.—In answer to "A Weaver," 22 lb. are quite sufficient for a strong stock, but as the stocks mentioned are old, I should give them about 5 lb. of syrup. As the combs in old hives contain an abundance of pollen which weighs very heavy, I should give them the syrup at once, in order that they may seal it over before the cold frosty weather, which is of great importance. I make my syrup for autumn feeding as follows: Put a quart of water in a saucepan; when it boils add 5 lb. of best loaf sugar, stir it until it boils again, then add a table-spoonful of common vinegar to prevent it crystalising; after which boil it ten minutes, stirring continually to prevent burning; do not put the vinegar in until it boils. A good way to feed bees in round-topped skeps which have no feed hole is to procure a tin canister, such as a ¼ lb. coffee or mustard tin make a small hole in the bottom, and insert a goose quill, which must fit tight and project about 3 in. from the bottom of the tin; make a small hole at the pointed end of the quill with a pin, so that the syrup runs down the quill and drops gently from this hole; then make a hole with a gimlet in the top of the hive, and insert the quill. The tin can be filled without removal, and the lid keeps strange bees from taking the syrup. Straw hives should always have a rain-proof cover; the bees are much more comfortable, and turn out stronger in the spring, and swarm earlier. At the end of February commence feeding again, using 3½ lb. of sugar instead of 5 lb.; feed gently and regularly, and at night the queen will then commence laying. It is the incoming of honey that controls breeding, not the contents of the hive, as bees are very cautious insects, and do not raise large families until they have the means to keep them. Therefore by giving food as directed you antedate the natural supply and breeding goes on apace.—A Berkshire Bee-keeper.

Supering Bees.—"J. B. W." should have supered his bees in the month of May or beginning of June to have prevented their swarming. Why bees work in supers is because they have not sufficient room in the hive; the cause why they did not work in them was because they did not need more room for their store. The diameter of supers will not prevent their taking to them. A small super for a weak stock, and a large one for a strong stock should be used. They do not require any ventilating hole at the top, or any beeswax as a guide. Glass supers require to be covered to exclude the light; a flannel cap fitted to them is the best covering.—Apiary.

Commencing Bee Keeping.—I fear you may give up your few rescued bees as lost; it will cost you much trouble and expense to keep them through the winter. Your best plan would be to get a bar frame hive, and in the spring tie into the bars with tape your clean comb and honey; then buy a swarm, shake them down into your hive, untie the tapes in ten days' time, put supers on in July, and by next autumn you will have reaped a good harvest of honey, and have a strong stock to winter. Cut out the dead brood; keep only the honey and empty comb.

—— "A Weaver's" two stocks should be quite heavy enough to go through the winter; he must be careful to keep them dry and free from insects. If he feed them freely in the spring when the Crocus is in flower, and give them some pea-flower in saucers (protected from rain) outside the hives, he will get strong and early swarms. He should feed them with syrup made from 1 lb. of preserving sugar to one pint of water and just boiled; put into pickle jars, the tops having muslin tied over them, and inverted over holes he has cut in the tops of the hives, all being carefully covered. Don't feed too fast (*i.e.*. keep the holes small), only enough to stimulate them and encourage the queens to breed.—One Taught by Experience.

HOME PETS.

Parrot with Sore Throat.—About a fortnight ago I purchased at an auction sale of birds a grey parrot; ever since it came into my possession it has been moping, and appears to be afflicted with a sore throat. I shall be very glad if some reader could supply me with a cure. The bird is in fine plumage, and is fed on Indian Corn with a little Hemp, which it prefers. I had a parrot for fifteen years which died last winter; since then I have bought two others, both of which have succumbed to this same throat disease.—Rob Roy.

Rabbits for Show.—Where can I obtain silver grey and Dutch rabbits? also what is the best method of getting rabbits up for show? What is the best kind of a "cote?"—W. G. Hackett.

TEA ROSE DEVONIENSIS.

TEA ROSES FOR INDOOR CULTURE.

Roses out-of-doors in June and July are unsurpassed in loveliness, but some of the best Teas and other varieties produced in spring under glass are equally beautiful and doubly valuable. All Tea Roses succeed well under glass, but some bloom much freer than others. The best Rose for clothing a pillar, wall, or any other extensive bare place under glass is Gloire de Dijon; the blooms of this variety, although very pretty, are not so attractive, perhaps, as those of some others, but the length of time during which the plant remains in flower, and the succession of bloom which it gives in twelve months, is perfectly astonishing. As is now pretty well known, the blooms are very globular in shape, and a delicate fawn colour, shaded with salmon. This variety grows and blooms in any half-shaded position equally as well as any other variety will do in the best of situations. Maréchal Niel is another magnificent Rose under glass in spring, and if it only produced its flowers for an equal length of time in succession, as Gloire de Dijon, it would probably be more valuable than any other Rose in cultivation. When in bloom it is superb, but it does not remain in flower very long. This is the only thing that can be said against this Rose, and that is not sufficient to deter any one from cultivating it; for if it only bloomed one week in the fifty-two, that would amply repay all the trouble that could be bestowed on it. The flowers, which are deep yellow, are very full in the centre, large when fully opened, exquisite in the bud state, and deliciously fragrant. Céline Forestier, a Rose strongly recommended by many, is in some places useless under glass. It grows freely enough, but yields no flowers. Madame Falcot is a splendid Rose in the bud state. Like most other Tea Roses, it is very poor when fully open; but, leaving this objection out of the question, it is worth growing in quantity on account of the great value of its buds. They are deep orange, or bronzy-orange, in colour, and they are produced freely both on small and large plants. Niphetos is a favourite Tea Rose for culture under glass, as it blooms so freely, and produces its fine large white buds and blossoms in such long succession. We would include it in the best half-dozen Roses which could be named for cultivating under glass. Devoniensis—which is illustrated in Messrs. Cranston & Co.'s catalogue (together with two new Hybrid Perpetual Roses, named Mary Pochin and Mrs. Jowitt, which are highly spoken of)—stands high in the list when the quality of the bloom only is taken into consideration. It does not not bloom under glass so freely as some kinds. Cheshunt Hybrid is good, although not the best; but it is worth growing on account of its bright cherry-carmine colour. Belle Lyonnaise is another fine climbing Rose, with beautiful canary-coloured flowers, deeply tinted with salmon. We find it better than Cheshunt Hybrid, inasmuch as it blooms freer and larger. Marie Van Houtte is also a magnificent Rose for indoor culture, and one which should be included in all good collections. Bouquet d'Or, Lamarque, and Solfaterre belong to the same Noisette section as Céline Forestier, but they are all much superior to the latter, and are well worthy of cultivation.

Roses under glass do best under much the same kind of treatment with regard to soil, &c., as that under which they succeed so well out-of-doors. Good loam, plenty of manure, and abundance of water at the root constitute their chief requirements. As to planting, that may be done at any time, provided the plants are in pots; otherwise spring is the best time to plant. A good bed or station should be made for them. The extent of rooting space is not of so much importance as having what is done done well. A good plant may be grown in a hole not more than 2 ft. square. Plenty of drainage should be placed at the bottom, and above that the soil should be rammed down firmly. In planting, the roots should be kept near the surface, and they should not be broken or much disturbed. Until growth has freely commenced water must be sparingly applied, but after that never stint the supply, a rule which should be closely adhered to, not only when the plants are in full growth, but also when they are at rest or growing little or none. This is one of the chief secrets of successful Rose culture under glass. Directions as to training must be left to those who have charge of the plants, as they know best what is wanted to be covered; but this much may be said—that the shoots should never be trained on the top of one another, and the greater the distance between them, reasonably speaking, the better they will succeed. The pruning of all Tea Roses should merely consist in thinning out the weakest of the shoots, and cutting in to keep the plant within bounds. Green fly is about the only insect to which Roses under glass are subject. It is particularly fond of attacking the points of the young shoots and bloom-buds, and should be cleared off them by close syringing before the blooms open; afterwards syringe them off as they appear, for the plants while in bloom cannot be syringed without injuring the flowers.

The following extract from "The London Market Gardens" may prove useful to those who wish to grow Roses under glass: During winter and early spring the blooms of Tea Roses always find a ready sale at good prices in the market, and although large quantities are imported from France, English growers, by aid of cheap glass, &c., and improved kinds, are beginning to compete on favourable terms with the foreigner. Whilst it is true that Continental growers have the advantage of a warmer climate, which enables them to produce Roses early at little expense, yet they have the disadvantage of losing a day or two in transit, which, even in cool weather, takes some of the freshness off the blooms. The Covent Garden florists, moreover, want flowers at given dates, and these they can only procure at short notice from English growers who are within an hour's ride of the market. One of the largest growers of Tea Roses near London is Mr. Ladds, of Bexley Heath, who has several span-roofed houses, 300 ft. long and from 35 ft. to 40 ft. wide, filled with them during winter and spring. The plants are grown in good, sound, sandy loam in pots varying in size from 8 in. to 10 in. in diameter, the plants being trained in the form of pyramids by tying the main shoots to an upright sta inserted in the centre of each pot; in th way the plants have a neat uniform appe ance, and do not take up so much space if trained in any other form. Potting usually performed in spring after the plan have ceased blooming, but very often th remain in the same pots for several yea unless their drainage becomes defective. the houses are not required for other pu poses during the summer, the Roses a allowed to remain in them, otherwise th are removed and arranged closely togeth in beds in the open air, kept well suppli with water at the roots; and in this w they succeed almost as well as when l under glass. One house of Tea Roses however, always retained for furnishing supply of bloom during the summer a autumn. The principal varieties grown a Niphetos (pure white) and Isabella Spru (golden-yellow); these kinds are profu bloomers; the flower-buds are large a perfect in shape; and as fully-expande blooms are never needed in the market, onl kinds that will produce a large quantity well-shaped buds are cultivated. From th middle of September till the end of Ma the quantity of Rosebuds sent to mark from this place averages from 70 dozen t 200 dozen every market morning. Thes are readily purchased by the bouqu makers, who pay from 3s. to 9s. per doze for them according to the season and th supply in the market. Every afternoo preceding the market days a man goes ov all the plants and cuts every bloom that fit, placing them as he does so on a larg shallow tray carried by a boy on his hea When all are gathered each bud has piece of soft matting tied round it middle to prevent the petals from ex panding and becoming injured. They a then carefully packed in boxes read to be sent to market early the next morn ing. Some florists near London grow Te Roses into enormous specimens in tubs o large pots, and others plant them out an train them over the roofs of houses; littl pruning in any case is done to Tea Rose Some growers have houses planted with them in which they are allowed to grow nearly wild, and the crops of flowers whic they produce is marvellous. The greates enemies Rose growers have to contend wit are mildew and green fly; the former is only kept in check by precautionary mea sures, such as dusting the hot-water pipe with sulphur when the plants are starte into growth, and the latter by frequent fumigation, a healthy airy atmosphere, fre growth in the plants, and frequent syring ings overhead. In most nurseries Te Roses are grown in some way or other, th plants themselves being often trained unde the roofs of the houses in such a manne as to obstruct as little light as possible fro the other kinds of plants which are grow beneath them. In other cases the plant are grown in large pots and trained up a series of trellises about 6 ft. or 8 ft. in height and from 3 ft. to 4 ft. apart. A pathway along one side of the houses admits of the blooms being easily gathered or the plants attended to. By this means the whole of the space is utilised most profitably, and the plants receive abundance of light and sunshine on all side. Examples of Maréchal Niel and Gloire de Dijon are the kinds

usually found planted out in large houses, the branches being trained, as before stated, in lines along the roof. I have seen plants thus circumstanced that had been planted only two years which have made over 35 ft. of growth each, some of the shoots being as thick as a good-sized walking-stick and bearing hundreds of blooms. Such kinds as Mrs. Bosanquet, Devoniensis, Madame Falcot, and Lamarque are highly esteemed by some growers; they are all excellent kinds in the bud state, but for general purposes there are no Tea Roses at present grown for market which equal Niphetos and Isabella Sprunt. Mr. Ladds, to whom reference has already been made, used formerly to grow large quantities of Maréchal Niel, but he now scarcely grows it at all.

TOWN GARDENING.

There are three great divisions into which town gardening may be divided:

1st, out-door gardening, *i.e.*, beds or borders in the open air; 2nd, window gardening, or the culture of plants in boxes or pots on window-sills, in which so many are interested; and 3rd, gardening under glass, in greenhouses, frames, &c. For greater convenience and simplicity we will treat of these separately and in the order given. The treatment of plants under glass is placed last, not because it is least in importance, but because comparatively few amateur gardeners have the assistance of glass. But we would strongly recommend every one who wishes to grow fine plants and flowers, that is, if they have any place or room at all for anything of the kind, to erect a greenhouse of some sort, or even a frame or two will be found a great help. Anything in this way is a wonderful advantage, as the glass keeps off such an enormous proportion of the soot, dust, etc., which would otherwise be deposited on the leaves of the plants, and greatly hinder their healthy growth by choking the pores. There are other obvious reasons why glass should be used in towns wherever possible, even if artificial heat cannot be applied. There will necessarily be some amount of repetition in treating of these three branches separately, but we will try to make each as clear as possible, and perfect in itself.

Out-door Gardening.

A great deal depends upon the situation. The best aspect for a garden is, of course, south, or south-east or south-west; but if the plot of ground faces the north, or from being overshadowed by high buildings only gets a little sun in the morning or evening, it is of not much use to attempt the ordinary run of bedding plants, as these, at least when planted out, require to be exposed to the full blaze of the sun, or nearly so. In such a position only such things as Ivy, Virginia Creeper, which will do well in almost any soil or situation, Creeping Jenny, Golden Feather, Ferns, &c., should be attempted. Most gardens of any size have, however, beds or borders facing in different directions, and the way to succeed is, not to put all kinds of things in at haphazard, as is the common practice, but to consider what aspect or circumstances will best suit each individual class of plants, and proceed accordingly. This part of the subject, however, may more properly be treated of under the heading of

Laying out Gardens.—This is a very wide field for remarks and recommendations. Situations vary, and a plan that would suit one place admirably would be totally unsuitable for another, so that no definite plan can be given. A garden laid out on paper, with little regard to the situation and circumstances seldom pleases. A favourite modern author says, "Set to work to mark out and plan a garden on paper, and whom will your careful dispositions satisfy? What a most unsatisfactory square has even the great Bacon mapped out in his celebrated garden essay; and where he has failed, none, to my mind, has succeeded. Cowper, be it observed, does not lay you out a garden, walks here and alleys there, and beds and lawn and pond all ticketed. He wisely confines himself to the general praise of a garden, and to certain episodes, incidents, and operations connected with the management of it. And in this success may be attained, but not by planning out the whole with stereotyped precision. The reason probably is that no two gardens can be exactly or nearly alike, that is, if they be worthy to be called gardens. A thousand nameless circumstances and special accidents make this curve proper for a walk, or fix that slope as the one spot for your purple Beech, or suggest a Fernery here; there an opening in the shrubbery, and there a circling advance of the Laburnums, Lilacs, and Laurels hemming in the smooth-shaven, shadow-flecked, golden-green lawn. You are struck by some arrangement in your friend's garden; you would repeat it in your own; a short trial shows that it won't do. And for this reason, that your garden has its own individuality, which differs from that of every other as much as does that of its owner from the idiosyncrasy of all his fellow-men." These words, though of course on a much smaller scale, apply to the laying out of town gardens. There is, without doubt, a general sameness about the small square or oblong and flat spaces attached to most urban residences, called by courtesy gardens; and we cannot have ponds, Ferneries, shrubberies, and sloping lawns within so circumscribed a space. But even here there is room and scope for a far greater variety than would at first sight appear, or than is generally attempted. The front of one house is exposed to the full blaze of the sun, and the scorched up little square of ground looks as if nothing could ever grow in it. But get the soil into something like a fit state, by breaking up all the hard lumps, bringing the whole into a nice, fine, sweet, and open condition, and working in plenty of rich manure, especially deep down, for the roots of the plants to feed on while the tops are exposed to the scorching heat, and the surface of the ground is quite dried up—and, if you like, plant a few trees, Plane or Lime; they will shade the windows from the glare of the sun nicely. Then fill a bed or two with scarlet Geraniums and Verbenas (Verbena montana is a capital kind for such hot and dry situations); some London Pride, Corn Flowers, or Marigolds and Nasturtiums, will make the place look quite gay with a little attention, and a good shower from the watering-pot morning and evening. And yet the last occupant has actually made a rockery there, and tried to make Ferns, and Primroses, and Violets grow. No wonder he gave it up in despair. Then very likely he planted a Vine at the back of the house, where it is always shady, and couldn't make out why the Grapes did not ripen. Now put your sun-loving bedding plants in the front, with the Vine or a Virginia Creeper to cover the bare walls, and construct the rockery in the shadiest corner at the back, and plant Ivy to cover the wall there, and your place will be a little oasis in the desert in a short while.

Another place will be just the reverse of this one, and, in short, there are hundreds of different positions, all of which want treating differently, but for all of which something suitable may be found. Tastes differ, and as far as possible let each follow his own, but it far better to carry out an arrangement that does not perhaps quite please you, if it is suitable for the place, and likely to succeed, than stick obstinately to one that can give nothing but vexation and failure. Remember also that, though in the country you can put things almost anywhere, and they will do more or less well, for instance, Ferns in the sun, Geraniums in a shady border, &c., yet here, where there are so many antagonistic influences, the only way to ensure success is to give everything the position best suited to its nature and requirements.

Lawns.—A bit of lawn should always be found room for if possible; it is astonishing what an improvement it is, and how it sets off the flowers. The light, excessively drained soil so often found in town gardens is very suitable for turf, far more so than anything like a clay or heavy loam, and we have ourselves had, in the very heart of London a lawn that would have put to shame those of many country gentlemen. There is no need for rich soil, except just on the surface; on the contrary, the subsoil is better to be light and rubbishy, and many a lawn has been greatly improved by paring off the turf pretty thickly, removing some of the soil, and replacing it by 2 or 3 in. of ashes. Do not lay down Grass sods, unless you have some very good turf ready at hand; it is expensive and unsatisfactory. Dig the ground over, level it, put about 2 in. of fine, light, rich soil (sifted if possible, and the siftings put underneath), and sow a mixture of fine lawn Grass seeds, purchased from a good firm, such as Carter's, Sutton's, or any well-known dealer, in April or September, preferably the former. Roll and cut regularly, but not with a machine the first few times; use a sharp scythe. Soak the lawn with water on the evenings of hot summer days occasionally, and give a dressing of fine soil, guano, and a little fresh Grass seed every spring. In this way a good turf may be had in six or eight weeks from the time of sowing, and you will have a velvety, weedless lawn, a thing of beauty, always before your eyes. A few beds cut out of the turf look nice if filled with bright flowers in summer; and if you can manage it, a fountain, with a basin as large as possible, and a few gold fish, is very pretty and entertaining. A few young trees carefully planted in suitable positions are effective, but remember that no flowering plants will do any good very near to these, and that they greatly exhaust the soil. Of course these things cannot be found room for in many places, but we are only offering suggestions, and you must do the best you can.

As regards arrangement, do not, as we have cautioned before, place a rockery at the foot of a sunny wall, and plant Geraniums and Verbenas in a shady place, but make your rockery in the shadiest, dampest corner you can find, set all Geraniums, Lobelias, Verbenas, Phloxes, Asters, &c., in the open borders or beds, where they will get every ray of sun and all the air, and on your hot border, under the south wall, sow major Convolvulus, Tropæolums, Nasturtiums, &c., to grow up and hide the bare ugliness of the wall until your Jasmines or Vines have grown; and have rows or patches of either sun-loving bedding plants, or if the soil is very dry and poor, and you cannot replace it with better, grow Sunflowers, Marvel of Peru (this is a splendid plant for such situations), London Pride, evening Primroses (Œnothera), Stonecrop, and if the air is not very bad, Sedums, Mesembryanthemums, and Portulacas will do. There may be other beds or borders facing more or less east or west which get a little sun morning or evening, or both; in these almost anything will do, but the most suitable for those where shade predominates are Auriculas, Polyanthuses, Primroses, Pansies, and Violets (where these will grow), Fuchsias, &c. Hollyhocks also like shade, but Dahlias should have full exposure to the sun. For covering sunny walls plant Vines and Fig trees (these do admirably in any town, and their large and handsome leaves are very effective), and for shady ones use Ivy and Virginian Creeper.

Shrubs break the monotony of lawn and flower beds admirably; and by far the best of flowering shrubs is the Ribes, or flowering Currant. This grows freely anywhere, and though our cold springs often cut off its blossoms just when they are opening, still it looks fresh and green all through the summer, and the pretty pink buds always appear, and occasionally get a chance to come to perfection. The next best is the Lilac, though this does not often bloom at all freely.

Stands of Flowers out of doors are not successful as a rule, as, from the dry harsh air or some other cause, plants in pots out-of-doors do not do well, so that the only way to manage anything of this sort is to have ornamental boxes or baskets, elevated on rustic posts to a height of 2 ft. or 3 ft., and filled with rich earth. In this almost any of the plants mentioned as suitable will grow; Geraniums, both zonal and Ivy-leaved, Petunias, Fuchsias, Lobelias, &c., are about the best for this purpose.

Cats to anything just mentioned are fearful enemies, and as they abound in all town gardens, and are especially fond of such elevated positions, regarding them as a kind of vantage ground or castle, in their nocturnal combats; so that unless you can effectually exclude them from the garden you are as likely as not to find your beautiful flower-stand a melancholy wreck some fine morning. These horrible cats are the bane of town and suburban gardens, as is only too

well known ; they destroy anything, and sometimes everything in the most complete and unexpected manner, and are most difficult to banish or exterminate, as one of our comic papers so well illustrated some time ago. After a considerable experience of the feline race, we have come to the conclusion that town cats are of quite a different race to their country cousins, and, indeed, partake largely of the nature of Diabolus, or the Evil One ; we think that anyone who has often heard the fearful howls in which they sometimes indulge about midnight will agree with us. We used to trace out their regular tracks, and, finding they went up and down the stems of three or four small trees to get to the top of a very high fence, we nailed bands of sheet zinc about 18 in. wide round the stems, and set a number of very sharp steel hooks, like very large fishhooks, pointing both upwards and downwards, to stop them. This our precautions succeeded in doing pretty effectually ; only one or two of the most agile could surmount these obstacles, and our garden was left almost in peace. Where there is a level wall round the whole or part of the garden, the best way is to arrange a width of wire netting, about 18 in. wide, stretched on light iron or wooden rods, inclining inwards at an angle of about 45°, along the top of the wall, or even a good width of the same set upright along the top of the wall, but with no firm rod or rail along the top edge on which the cats might get a footing. Cats are very fond of eating and rolling on the Nemophila, for which reason, though it grows vigorously, we have excluded it from our list of suitable plants, as we have found it impossible to keep them away from it, and they completely destroy it.

(To be continued.)

FRUIT.

Apples and Chrysanthemums.—It is interesting to note that in the estimation of even such a fruit-growing people as are those about Maidstone, cut blooms of Chrysanthemums are held in much higher esteem than first-rate Apples. No doubt the prizes of £5 5s. for the best eighteen dishes of Apples, and £10 10s. for the best thirty-six single blooms of Chrysanthemums, to be competed for at the Maidstone show next month, will bring a large competition and first-rate subjects ; but can any thirty-six Chrysanthemum blooms be found that are more valuable than perhaps some 150 fine Apples, the which when staged will make four times as fine a display as the flowers, and can be eaten after the competition ? I know I amongst gardeners am not alone in thus deploring how much at shows of all kinds fruit is put into the background when flowers are about. Fruit is of the first importance to the nation, and certainly should receive a greater meed of encouragement than is now afforded outdoor Grapes.—A. D.

Vines in the Open Air.—From young Vines planted two years since against a south wall I have taken well-ripened bunches of Sweetwater, and even good coloured ones of the Madresfield Court Grape. This year the wood made has been very strong and firm, and now it is well ripened. The foliage is yet stout and green, and even as a leaf plant for covering walls or a house the Vine is valuable. I have several kinds planted out besides those that are of hothouse reputation. As they have ripened wood so well, perhaps with a warm summer next year I may get some good fruit. The position is warm, and the Vines like the soil. There is not a speck of mildew this year.—A. D.

Cranberries. — With very little care several of the hardy kinds of fruit-bearing bushes, both native and others, might be turned to profitable account under ordinary garden cultivation. I recollect that in a rather celebrated garden in the north of England, Oxycoccos macrocarpus, which we now figure, and Oxycoccos erythrocarpus were both grown as useful fruit-bearing bushes, especially the former, which was regarded (I believe rightly) as the true American Cranberry of commerce. The mode of cultivation was very simple. In a certain wild part of the pleasure ground, wet, and sloping south, four or five beds were formed horizontally across the slope. The beds might be about 6 ft. in width, made up of bog earth. These beds were divided from one another by ditches 3 ft. or 4 ft. across. The drainage of the hill-side was concentrated to this point, and the water discharged first into the higher or uppermost ditch. All the ditches were kept full of water to within 6 in. or 12 in. of the surface-level of the peat beds. At this height the water was allowed to overflow into the next ditch below—say at the west end, then at the east end, and so on from one ditch to the other, maintaining thus a slight current throughout from the highest to the lowest. In these peat beds this pretty evergreen trailing plant grew luxuriantly, thickly covering the bed with a mass of growth, and in the season abundance of fruit. The O. erythrocarpus, being of upright growth, was planted along the centres of the beds at distances of 10 ft. or more apart. These also bore fruit, though sparingly.—R. M.

Planting an Orchard.—In preparing the holes prepartory to planting the trees one can only reiterate that which has often before been

American Cranberry (Oxycoccos macrocarpus).

quoted, viz., make but one hole—in other words, mellow the soil so deeply that the size of the hole itself will be a matter of small moment. The depth of the hole is, however, of some importance ; in my opinion it should not be too deep, but merely sufficient to allow the tree to stand at the proper depth. Tap roots will work their way down almost in spite of all obstructions, but the delicate fibres and small roots that provide the nourishment should have light mellow earth in which to ramble. This is a common-sense view of the subject, and it is borne out in practce. Deep holes not unfrequently serve as receptacles for holding water, especially in clayey soils ; and when planters fill in the bottom with stones, no benefit of course is derived therefrom, as the accumulated water has no vent. In soils retentive of moisture trees should be planted even more shallow than they usually are, but in all cases it is a good rule to bear in mind that trees should always be set shallow. Concerning the selection of trees, planters differ. Most prefer small trees, but success is often attained with trees of large size. There is this difference : a person to succeed with large specimens must first thoroughly understand the nature and requirements of his trees and be versed in his work, otherwise he will fail ; but the merest novice with small trees, under ordinary circumstances, will not have many to replace. In respect to the selection of nursery trees, I prefer Apples three, or, at the furthest, four years of age ; Pears, two or three years ; Plums and Cherries, two years ; and Peaches, one year. These should all be strong and healthy, which is shown not only by the size of the previous year's growth but by the peculiar glossy appearance of the bark. A tree that has been unduly stimulated and forced into making a remarkably strong growth is not so valuable as one of small size with healthy, ripened wood ; and the latter, in the majority of instances, will come into fruiting in advance of its more robust competitor. The Grass question, in its application to orchard culture, is one over which there has been much disagreement among practical men ; but I doubt if the most strenuous advocate of seeding down to Grass would recommend the practice as soon as the trees are planted. The proper plan is to cultivate carefully for a few years until the trees have become well established, and then allow a turf to form, depending afterwards upon top-dressings.—S.

Culture of the Raspberry.—A cool, deep soil suits the Raspberry best, and in all such positions it is a very paying crop ; but almost any soil, however unfavourable it may be in its general characteristics, can by trenching and manuring be made capable of producing very good fruit. There are two systems of culture that I think are admirably adapted for the successful development of the Raspberry in small gardens. The first is to plant in rows 15 in. from plant to plant, and from 5 ft. to 6 ft. between the rows, and train the canes diagonally to espaliers 4½ ft. high ; two wires will be ample, one at the top and the other about midway between that and the ground. Drive in some stout Oak stakes 10 ft. or 12 ft. apart (having previously charred the bottoms to preserve them), and strain the wires on them. This is work that can be done by any ordinary labourer, and will not cost so much as placing a stake to every three or four canes when grown in clumps, and the fruit will certainly be finer and better. The other plan is to grow them in rows 15 in. apart and 4 ft. between each row, but not to train them at all, simply thinning out the young wood well in spring to admit as much light and air as possible, so that the canes may be strong and short-jointed. When the fruit is gathered cut out all the old canes that have ceased bearing, and still further reduce the number of young canes, leaving only enough to produce a crop the following year. Success will be in proportion to the way in which these details are carried out, for almost everything hinges upon having sturdy, short-jointed canes. In February cut back the canes to 3 ft. and mulch with manure. As Raspberries are surface-rooting plants, it is not advisable to dig amongst them. On dry, porous soils it will not be necessary to disturb the surface at all if it be mulched, but very retentive land, if not stirred, sometimes becomes sour and unwholesome after much treading, and should be forked up in autumn to aërate and sweeten it. The autumn-bearing Raspberries will succeed in a somewhat drier position than the summer bearing kinds. They are, perhaps, not much grown in small gardens, but they are very useful to mix with late Red Currants in a tart, or for an occasional dish for dessert. Their treatment is different from that of the summer-bearing varieties, inasmuch as they are cut down close to the ground every autumn, the effect of which operation is to induce the canes to throw up a new growth from the roots in spring. This new growth should be well thinned out, leaving only the strongest shoots for fruiting.—H.

Bamboo Flower Stakes.—These form the best of all stakes for garden work, and, being largely imported as a kind of packing and separating material, they are cheap. They require no dressing, or trimming, or rounding, and have a polished surface, better than any paint or varnish could give them. The portion thrust into the ground lasts several years, after which it may be cut off and the stake used in the ground again. They may now be had from most nurserymen and dealers in gardening requisites.

PLANTS IN SHADY GARDENS.

In a garden which gets four hours' sun daily there should be no great difficulty in inducing many beautiful kinds of flowers to thrive. In the first place, however, I should warn those who may have naturally unfavourable situations to deal with, that they must not expect to attain such perfection of culture, or enjoy so much variety, as it is possible to do where the conditions necessary to the well-being of plant life are at the command of the grower. Even professional gardeners of good attainments often find considerable difficulty in this way, and are sometimes obliged to relinquish the culture of favourite plants because soil or situation are not sui able. When the surface soil and the pots get covered with Moss, it is a sign that either the atmosphere is too moist or that too much water is given. Defective drainage is also a prolific source of mischief, as the soil remains in a saturated condition for a considerable period. Any plant which may appear to be suffering should be at once inspected, and should the drainage appear to be choked by dirt, wipe out the pot carefully, give fresh drainage, and replace the plant. It is also a good plan to work off some of the surface soil and top-dress with fresh mould. These little attentions in combination with careful watering will often suffice to bring a plant out of its feeble, unhealthy state, giving it a renewal of life and vigour. And now with respect to watering; banish at once and for all the absurd idea that plants require water at stated intervals. Such notions as this are too prevalent, and are often the cause of good plants going to the bad. Where the sun does not penetrate freely, great care must be taken not to give an overdose of water to any plants growing there, especial care in this respect being needed in the case of such tender subject as cannot be exposed to a free circulation of air. Ferns, for instance, which love the shade, are soon irretrievably injured when watering is conducted with a heavy hand or in a careless, haphazard manner.

Where the sun comes but little, Ferns and Club Mosses may be successfully grown. They delight in shade and moisture, and thrive perfectly where flowering plants generally fail. The great point is to avoid over-potting, and not to over-water. An excellent subject for a north window is the Moneywort, which forms a dense curtain of deep green foliage which, when thickly studded with golden-yellow flowers, presents a most cheerful appearance. This plant likes plenty of moisture, both at the root and on the leaves, and will succeed in any confined situation. Other shade-loving subjects consist of the Wandering Jew Saxifrage, which forms a fine basket plant, London Pride, Myosotis dissitiflora, Nertera depressa (a pretty little alpine bearing in winter a profusion of scarlet berries), Primula denticulata, and P. cortusoides amœna. Then there are the many beautiful varieties of Primrose and Polyanthus, which are well fitted for pot culture, and require but little sun, and flowering bulbs, such as Daffodils of many kinds, Triteleia uniflora, Scilla sibirica, and Hyacinths. We would also try Lilium speciosum and L. auratum, which do not like much sun when growing, and do very well in the confined precincts of a town. Pot them now in peat and loam, and grow them in the open air in the summer. Cuphæa platycentra (the Cigar Plant) is a free-growing, profuse-flowering subject, thriving well in partially shaded situations, and the Paris Daisies are highly recommendable subjects of the most easy culture. Such sun-loving plants as Geraniums and Fuchsias cannot, of course, be expected to flower so freely in confined quarters as when fully exposed to sun and air. Where they get several hours' sun daily they should, however, give some bloom; and we would try a few annuals, such as Nemophila, Bartonia, Clarkia, Collinsia, Godetia, and Leptosiphon, sowing in pots or in the open ground in September and March. The autumn sowing would come into flower early in the year, to be succeeded by those sown in spring. Pansies and Violas should not be omitted, as they do not mind a little shade in the summer.

J. C.

Double and Single Wallflowers.—Double Wallflowers require exactly the same kind of culture as the single-flowered kinds, with the exception that when a really good strain is procured from seed the plants are best propagated by means of cuttings. In favourable seasons early planted Wallflowers afford abundance of bloom throughout the winter and spring months, and they are general favourites with every one. Wallflowers may be profitably grown between fruit trees or in other shady places, where they thrive remarkably well. The seed should be sown in a bed in the open air in February, and when the plants are large enough to handle they should be transplanted 12 in. apart. During summer, if the place they occupy be very much shaded, they often become a little "drawn," but as the leaves fall off the trees in autumn they begin to branch out and grow well, and by December many of them are in bloom. After all the flowers have been cut, the plants, except the double-flowered ones, may be dug up and thrown away, and replaced by young seedlings, which are by that time ready for transplanting. Before planting, however, the ground should be always liberally manured and deeply dug. Young plants in every case produce the most and best bloom. Seeds should be saved from plants possessing the best branching habit, and which bear the darkest-coloured blossoms. When in flower go over the plants and mark those possessing these qualities by placing a stake by the side of each. Allow these to remain undisturbed until the seed is ripe, when they may be pulled up, roots and all, and housed in a dry place until a convenient season arrives for threshing out the seed. Cuttings of the

Double Wallflowers.

double kinds may be put in as soon as they can be got after the plants go out of bloom. Put them in firm sandy soil under a handlight, and when struck plant them out. Cuttings put in in August, September, or October will strike freely without any protection in a shady border, or in pots or boxes filled with sandy soil.

Veitch's Virginian Creeper (Ampelopsis Veitchi).—I have found this to be a very valuable climber, both for covering walls in the shade and in exposed situations, and the rapidity of its growth is surprising. Its leaves, too, are most useful for garnishing fruits and for table decoration during the autumn months. No plant is more easily propagated. We put in some cuttings of it two years ago as one would Ivy. They all rooted, and were planted thickly on old walls and other suitable places. Plants of this Virginian Creeper also make beautiful coverings for old stumps of trees, rustic flower-stands, and for rockwork.—M. T.

A Neat Hardy Shrub.—Among the plants in Covent Garden we notice Euonymus microphyllus, a very compact and attractive little shrub, looking at first sight like a small Box tree or a very close-growing Myrtle. It has, however, the very leathery leaves of its own evergreen relations, so that it will probably prove useful for town and sea-shore gardens. For general cultivation, too, we should say it will prove a valuable plant, from its distinct habit of growth and its bright green polished foliage.

CLEMATISES IN MIXED BEDS.

Although our fine hardy Clematises have increased in numbers and variety and cheapened in price during the past few years, yet they have not been utilised to the extent to which they might be made serviceable. Occasionally one meets with C. Jackmani trained to a wall, or used for pillar purposes, or for covering archways over walks, and sometimes plants of it are employed in beds, but only unfrequently so. In respect to the latter mode of utilising them, they can be made of great service as permanent bedders, using something else in association with them to prolong the flowering season to the greatest extent. There is one advantage about the Clematis, that is, when planted out for permanent service, if the roots be mulched in summer and manured in winter, the plants increase in strength and vigour, and this means, under good management, a greater quantity as well as heightened beauty in the flowers.

The pretty and free-blooming spring flowering varieties have not been so much used in our gardens as they deserve to be. They are characterised by free growth and a greater hardiness of habit than is generally supposed. I can particularly recommend the following varieties: Albert Victor, deep lavender; azurea grandiflora, pale mauve-lilac; Gem, deep lavender; Lady Londesborough, silver-grey; Lord Londesborough, deep mauve; Miss Bateman, pure white; Standishi, deep lilac, free and attractive; and Victor Lemoine, violet tinted with blue. Here, then, are eight varieties that would make charming beds in spring; but, in order to give the beds a furnished appearance, I would also plant them with Tulips, Hyacinths, Ranunculuses, Anemones, and other early-flowering subjects that would precede the Clematis. The profuse growth of the latter spreading over the bulbous plants would do them no harm, as after they have done blooming, the Hyacinths and Tulips would be comparatively worthless. A few bulbs of Gladioli dotted about the beds and some later-blooming Lilies would carry on the flower till late in the summer.

If it be objected that the spring-flowering Clematises are apt to be cut back by frost, a few branches of Spruce, Fur, or any evergreen laid over the beds would ward off the effects of the frost and keeps the flowers from injury. It is not necessary to plant many specimens in a bed. For small beds one or two may be used, according to their size; for larger beds three or four. The longer a plant is established in the soil, the more vigorous growth does it make, and if a number of plants were introduced to a bed in the first instance, some should be taken out as the others increase in size and strength. One caution is necessary here. The spring-flowering Clematises flower from the wood made the previous summer, and the grower should be careful not to cut it back, but simply thin it out, removing only the decaying and weak shoots, and shortening back the immature growths at the points. When the old wood is spread out on the beds after planting with bulbs or any other plants, it should be so distributed as to give the beds a furnished appearance when the shoots break into leaf.

Of the summer-blooming varieties, which may be said to flower from early in July till October, the following are well adapted for bedding purposes: Alexandra, pale reddish-violet; hybrida splendens, velvety purple; Jackmani, deep velvety purple; Lady Bovill, soft greyish-blue; lanuginosa nivea, pure white; magnifica, reddish-purple; Otto Frœbel, greyish-white; rubro-violacea, maroon-purple; Star of India, reddish-plum; tunbridgiensis, deep bluish-mauve; velutina purpurea, blackish-mulberry; and Viticella rubra grandiflora, a very fine Clematis, bright brick-red, very distinct in colour, small-flowered, but very free.

Bedding Violas or Pansies.—As concisely as possible I cheerfuly contribute my quota to the Pansy selection asked for on p. 391. Of blue-flowered varieties I take Blue King as the best early; flowers large, of good form, and of a cheerful blue; a capital kind for spring bedding. Blue Bell, next early and the most constant of all for summer and autumn blooming; flowers small, but most freely borne; a first-rate habit. Last, Blue Beard, a fine summer bloomer; flowers of good size and intense deep blue; habit dwarf, very free, and very

constant. Of purples, the earliest is the old Clivedon Purple, very effective in the spring and early summer. Mulberry—flowers of fine form and good substance, rich colour; habit dwarf and spreading; a very effective kind and hardy. Last, Duke of Perth, a Pansy-like kind; flowers large and showy; habit dwarf, spreading, and a good bedder. Of whites, Vestal, a true Viola; flowers of medium size, very freely borne, capital habit, and a capital summer bedder. Mrs. Pease, very pure white, early, free, and of excellent habit; and White Bedder, an improvement upon the old Clivedon White; flowers not pure, but in the mass very effective. Of yellows, the earliest of all is Yellow Boy, a true Viola, the best of all for spring gardening, wonderfully free, and very effective; Sovereign, semi-Viola, dwarf, free, and rich colour, very telling, and continuous for summer bedding; and last, Clivedon Yellow, a universally grown kind, having a fine habit, and blooming most freely and continuously. To these I would add Lilacina, very dwarf habit, flowers abundantly, in colour lilac-mauve; a very distinct and charming kind.—A. D.

Hollyhocks amongst Rhododendrons.—Of all the herbaceous subjects which we possess for planting immediately in front of evergreen shrubs, so as to have the latter for a background, none surpass Hollyhocks; not only are the colour and form of their flowers seen to the best advantage when backed up by a dense mass of green foliage, but the erect habit which such plants possess contrasts admirably with the spreading growth of Rhododendrons.

Boots for Wet and Mud.—I have stood in mud and water, 2 in. to 3 in. deep, for ten hours a day for a week without feeling any dampness or having any difficulty in getting my boots on or off. If you would be equally successful, before wearing your boots give the bottoms a good coating of tallow and tar and dry it in; then oil the uppers with castor oil—about one tablespoonful will be sufficient. The effect of castor oil is to soften the leather, while it fills the pores and prevents the water from entering.—F.

Destroying Wasps.—Some years ago, whilst living in the country, many complaints were made of the wasps stinging children, &c. Some half-dozen nests in a bank being pointed out to me, I took a small bottle of bromine and poured a few drops into each nest. In a short time I was enabled to dig up all the nests and destroy the grubs. Not a single wasp survived the treatment.—Chemist.

GLASSHOUSES AND FRAMES.

Passiflora quadrangularis.—We have a plant of this Passion-flower planted in an 8-in. pot trained up the roof of our greenhouse. It never fails to give a good supply of bloom from now until near Christmas; let me recommend any one who has a warm greenhouse to try this plant. Passiflora cœrulea is the well-known hardy kind which gives a succession of bloom through autumn till cut down by frost. The meaning of the Passion-flower is as follows: The leaf represents the spear, the five points the five wounds, the tendrils the cords or scourge, the ten petals the ten apostles (Judas having betrayed, and Peter denied Christ), the stamens the hammers, the styles the nails, the inner circle the crown of thorns, the radiance the glory, the white tint purity, the blue tint heaven, the centre pillar is the cross, and lastly blooms three days, and then dies.—J. Winfield, *Llanstephan*.

Veronicas for Cutting. — Veronicas should be grown more extensively than they are, for they yield an abundance of flower-spikes fit for cutting until late in the year when outdoor plants become somewhat scarce, and, being of many shades of blue, they intermix well with flowers possessing brighter colours.—J. G.

True Maiden-hair Fern (Adiantum Capillus-veneris) **for Covering Bare Walls.**—In a plant house in a nursery near London I lately saw this beautiful Fern growing most luxuriantly on the bare wall surrounding a bed in the centre of the house on which plants are set. The wall in question is about 3 ft. high, some 50 ft. or 60 ft. in length, and thickly clothed from top to bottom with the beautiful green fronds of this lovely Fern. Being a surface-rooting plant, it is better adapted for this kind of ornamentation than most other varieties; and when grown in this way, it is, in addition to having a fresh and dressy appearance, most valuable for cutting for bouquets, &c. When the fronds begin to look shabby, they should be cut off here and there, by which means a continuous succession of fresh, green fronds may be obtained.—S.

A good Autumn Flowering Plant.—Schizostylis coccinea is one of the most valuable of plants, either for conservatory decoration or for growing in any warm, sheltered nook for supplying cut flowers during autumn. In order to have strong plants it should be planted out early in the spring in beds specially prepared for that purpose, as it grows much more vigorously treated in this way than it does when confined in pots. The beds should be formed of some rich vegetable material, such as leaf soil and good fresh loam, or any refuse peat that has been cast aside as unfit for potting purposes. If either of the above materials can be spared to form a bed from 6 in. to 10 in. deep, there will be no difficulty in growing such plants of Schizostylis as will produce an abundant supply of its rich scarlet Gladiolus-like blossoms during the greater part of the winter. Where supplies of leaf soil or peat are not to be had, it may be grown tolerably well in any ordinary soil that has been well enriched with rotten dung previous to planting. Its flag-like leaves are rather subject to red spider, but this may always be prevented by keeping the plants well supplied, when necessary, with water, as it is invariably over-dryness, either in the atmosphere or at the roots, that favours the existence of this pest; both may, therefore, be guarded against by sprinkling the plants overhead two or three times a week, or as often as the weather renders such a course necessary or desirable for the health and well-being of the plants. If treated in this way, they will be found to produce flower-spikes early in October, when they may be taken up and placed in pots according to the size and strength of the tufts. They should then be placed in a close, moist frame for a week or so, to give them a chance of becoming established before being placed in the comparatively dry atmosphere of a greenhouse or conservatory.—J. S.

Culture of Lilium auratum.—Those who wish to attain complete success in the culture of this handsome and fragrant Lily must, in the first place, procure sound, well-ripened bulbs. Cheap, imported bulbs cannot be relied on to flower well the first year, the long journey which they have to make before reaching this country having the effect of lowering their vitality to such an extent that even the most careful culture fails sometimes to induce a free growth. The best way is to buy home-grown bulbs, as if dearer they are, in the end, cheaper, and one good bulb is worth several weakly ones. If, however, small bulbs be purchased, let them be potted at once in small pots, say 4½ in., in two-thirds peat and one-third loam, leaving about 1 in. of space for top-dressing in the summer. Water very gently and plunge the pots in a cold frame, or place them in a greenhouse or outhouse. About the latter end of May place them in the open air in a sheltered, shady situation, bringing them as soon as the first flowers fade into the greenhouse. Allow the plants to remain under cover, keeping the soil on the side of dryness until the leaves turn yellow and the stems die. This treatment will mature the bulbs, so that by the beginning of November they may be shifted into the next sized pot and treated as before. In this manner the bulbs will yearly increase in vigour, so that by the time they come into 8-in. pots they will form handsome specimens bearing many beautiful blooms.—J. C. B.

Edgings of Lycopodium.—Nothing is more objectionable in conservatories or plant houses than bare patches of earth, such as occur when the drip from shelves or staging makes it a difficult matter to keep any sort of vegetation in good condition. Under these circumstances I have found the following simple method to be the best for keeping that loveliest of green carpet plants, Lycopodium denticulatum, in good condition for a lengthened period. After laying a good coating of light porous soil over the bed or edgings that it is intended to cover I insert plants of the Lycopod about 1 ft. apart, and cover the space between them with clinkers from the furnaces. The Lycopod quickly covers the entire surface, and this being so well drained, the plant flourishes amazingly without damping off as it does if resting on the soil itself.—J. G.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

November 1.—Planting Crocuses in the flower garden; re-planting Daisies; putting all scented Verbenas under greenhouse stage for stock, also double Wallflowers into 4½-in. pots and placing them in frames; putting first Tulips into heat; placing a few Heliotropes into heat weekly, also all Bouvardias into a warm pit; digging ground for first sowing of Peas; pruning early Vines; raking up leaves for hot-beds, &c.

Nov. 2.—Potting Sweet Briers; putting in Rhubarb for forcing; taking up Dahlia roots, and putting them under greenhouse stage in not too dry a place; tying up tree Mignonette; also creepers on screen walls; and Lettuces in frames; putting lights over Strawberry plants in pots; putting litter round the Calceolaria pit; pruning Pear trees; keeping tree Carnations at about 50°. Plants in flower—Chrysanthemums, Salvia splendens, Erica gracilis autumnalis, Cytisus racemosus, and C. Attleanus, Epacris Eclipse, Tydæa splendens, Begonia parvifolia and incarnata, Tom Thumb Pelargonium, Primulas, Mignonette, Crimson Monthly Rose, Cinerarias, and Lobelia splendens.

Nov. 3.—Planting standard Roses in flower garden; taking up blue Salvias for stock plants; taking out autumn Cucumbers to prepare for re-planting; putting hand-lights over early Lettuce; stacking Carrots and Beetroot in dry sand or dry ashes; clearing out a pit for Asparagus forcing.

Nov. 4.—Potting herbaceous Calceolarias in good rough material, and placing them in well-crocked pots; a quantity of Sedum spectabile; taking up Gladioli; putting in first batch of Seakale for forcing; getting all Cauliflower which is ready put into trenches; washing Gardenias; watering bedding material when absolutely necessary; manuring vacant ground with garden refuse.

Nov. 5.—Potting Lily of the Valley for forcing; also a large quantity of Narcissus; planting Gentiana acaulis and Pansies; plunging the most forward bulbs in tan, and keeping them at from 58° to 60° at night and 63° by day with air; extra covering Lettuces, Endive, Strawberries, Calceolarias, Chrysanthemums, and cold frames on signs of frost; getting all Fuchsias and Daturas under greenhouse stage; putting some hay over seed Potatoes; taking up untied Endive and putting it into a frame; examining Camellias for scale; making a pit ready for forcing Seakale; cutting Ivy off top of wall to prevent its being broken down by heavy wind or snow.

Nov. 6.—Putting all young Heliotropes from pits into span-roofed house to keep them dwarf for Christmas; putting a little tan over potted Lily of the Valley and protecting all other plants in pots; hanging up in cellar all Cauliflower that is ready head downwards; gathering all Tomatoes and putting them in Vineries; digging vacant ground; emptying two frames so as to have them ready for early Carrots; pruning Raspberries.

Flower Garden.

As far as regards outdoor flowers the season may now be said to be at an end, as there are only a few Antirrhinums, Michaelmas Daisies, Pansies, Violas, and here and there a Rose left. Vacant beds should be at once dug or trenched, both for the sake of neatness and the full action of the weather on the soil. Roses will now be much benefited by a good layer of well-rotted manure; it should not be dug in, but if thought unsightly it should be smoothed over with a spade, and covered with 1 in. of fine soil or Cocoa-nut fibre refuse. Now is also a good time to plant Roses, and by doing it thus early, they will next season bloom as profusely as those that have been planted two or more years. Standards, or others that are large enough to be affected by wind, must be securely staked as soon as planted. In the preparation of beds for Roses, it should ever be borne in mind that they cannot well be too rich, or the soil too deep, but it should be well firmed previous to planting. As soon as the leaves are all down, shrubbery borders will require to be lightly forked over, and in the meantime any re-arranging, thinnning out, or filling up of vacant places can be done, as also the lifting and relaying of Box edgings, or filling up gaps in the same. Necessarily much time will now be taken up in the maintenance of neatness; just now worm casts are a terrible eyesore. The best remedy is lime water, the next best remedy is to roll the lawn as frequently as circumstances permit. Walks that, owing to the shallowness of the gravel, are subject to worm casts, may be effectually cleared of them by a sprinkle of salt, but care must be taken that the Grass verges or Box edgings are not injured by it.

The present is also a favourable time for making new or altering existing walks, and the material used has a long season in which to get consolidated before dry weather hinders the roller from having due effect. Old walks on which the gravel is discoloured or Moss-grown may be improved by forking up the gravel and applying a little fresh material to the surface, and well rolling them, particularly after heavy rains.

Pansies and Pinks in Beds.—The ground about the roots of these should be kept well stirred, and for this purpose small Dutch hoes about 4 in. wide answer best. Beyond this they require little more attention, except to see that the plants are steady in the ground. The soil should be pressed round the roots with the fingers, and some of the plants may be tied to small sticks to steady them. Slugs and the leather-coated grubs must be searched for at night.

Pinks for Forcing, comprising such sorts as Anne Boleyn, Derby Day, Lady Blanche (the best pure white), Lord Lyons (fine rosy-purple), Mrs. Pettifer, and Newmarket should now be lifted from the open ground and potted in good soil. If the plants are large they should be potted in 5-in. or 6-in. pots, and small plants in 4-in. ones. Place them in a cold frame near the glass, where the lights must be kept close for a few days, and then air may be freely admitted.

Pentstemons.—If cuttings of these have not yet been put in, no time should now be lost in doing so; they ought to be put into fine soil under hand-lights, either in pots or in the open ground. Our plants are now flowering freely, and most useful the blossoms are, as nearly everything else has finished blooming. If seeds are not required see that the seed-pods are removed.

Glasshouses.

Camellias require more water at all seasons than most plants with hard wood. If ever the soil be allowed to get dry from the time the buds have attained a considerable size until they expand, it results in their falling off. The same result will follow if the atmosphere be too dry, but injury from this cause mostly shows itself much sooner in the case of plants having been dry at the roots. The autumn-flowering Speedwells (Veronicas) require the soil kept moderately moist, especially while they are blooming, or the flowers will be liable to drop. Cytisus racemosus, Acacias, Neriums, Myrtles, Statices, greenhouse Rhododendrons, Lapagerias, Croweas, Clianthus puniceus, Cassia corymbosa, and Abutilons are plants that should never be allowed to get so dry as the more tender kinds; they are free growers and equally free in producing flowers, afford great variety, and are altogether much more suitable for those to grow whose experience is limited than plants that are of more difficult management.

Azaleas, although fine-rooted subjects, should never be permitted to become dry. The exquisitely-scented Daphne indica, held in universal estimation for its perfume, is often killed by over-watering; except during the season when it is making growth, it should never be watered until the soil has got almost dry. Oranges, especially the small-growing Otaheite variety, need careful watering in the winter, when its roots are at rest. Fuchsias that are cut back in the autumn after flowering are much better if the soil be kept very nearly dry. In all cases, except with subjects the tops of which die completely down, or nearly so, when water is applied no more should be given than will moisten the whole moderately in the winter season; to pour water on a plant until the soil is saturated during the winter, when at rest more or less, is as bad a treatment as can possibly be followed, especially if the soil is loose and light, as in this case the soil will hold water like a sponge. When a plant of any description is growing in a pot comparatively small, it should never be so dry before water is given as if it had a larger body of soil surrounding its roots.

Calceolarias and Cinerarias.—In addition to a moist condition of the roots, these revel in a humid atmosphere, and should never be placed on a dry surface, such as the front shelf of an ordinary greenhouse. Through the winter the best position for them is on a bed of ashes in a shallow pit, a slight distance below the aperture for the admission of air, so that it will in a measure pass over rather than come in direct contact with them. Where there is no alternative but to put them on shelves, it is well to have 1 in. of Moss spread on the shelves, which, if kept moist, will counteract the drying effects of the situation.

Richardia (Calla) needs to have the soil moist; although it is almost an aquatic, it is of such an hardy nature that it will bear to be completely dried up without fatal results, though, of course, it feels the effects of such treatment. Heliotropes, Petunias, Lobelias, Carnations, Salvias, Lachenalias, Vallotas, and Cyclamens do not require to have the soil kept quite so moist as the first-named plants, yet they should always receive water before being allowed to get quite dry.

Lilies do not need much water in the winter, but though not making much progress in their tops at this season the roots are actively at work, consequently the soil must never be without moisture, or they will receive a check that will seriously affect their flowering the ensuing year.

Pelargoniums.—The different sections of these vary considerably in their demand for water; the zonals of all colours and the bronze and white variegated-leaved kinds being mostly freer growers than the large-flowered sorts, the fancies, and the tricolors, must have the soil kept somewhat moister, but those who have not yet acquired the knowledge of the exact condition of moisture these plants like had much better err by keeping them too dry than too wet, as the latter state will cause destruction of the roots, resulting in disease from which they will be slow to recover, whilst a moderate degree of dryness will not affect them to a greater extent than slightly stopping their growth. The above-mentioned more tender-rooted, slower-growing sections, particularly the fancies and the weakest growing varieties of the tricolors, should never be watered during the winter until the soil has got so dry that little moisture can be detected in it by pressing the fingers on the surface. There is a considerable difference in the strength of growth of the yellow-leaved varieties of Pelargoniums.

Crassulas (Kalosanthes) must be watered with caution until they begin to move freely in spring, when they will need more; during the autumn and winter do not apply any until the soil has got almost dry, yet water must not be withheld too long or the under leaves will shrivel up and die, which detracts much from the appearance of the plants, yet does not usually interfere with their flowering.

Auriculas.—These should be carefully looked over at least once a week, removing all decaying foliage, weeds, and green mould from the surface of the pots. Insect pests are still active; the worst—greenfly—can be readily destroyed by fumigating with Tobacco smoke. There is also a pale green caterpillar not easily distinguished from the leaves on which it feeds that is very troublesome at this season; therefore carefully search for it and pick it off. The leather-coated grub, too, will eat the leaves rapidly; this and slugs must likewise be sought for at night with a lamp. Very small offsets put in late are difficult to winter, unless they are very carefully attended to. The soil in the pots should be kept only very moderately moist. Pull the lights off all frames in which Auriculas are growing, except when it rains.

Fruit.

When the foliage of Apricots, Peaches, and Nectarines part readily from the trees, they ought to be occasionally lightly brushed over for the purpose of bringing it down, in order that the sun and air may have full play on the trees. Push on planting, lifting, and root-pruning, as the present is the best season of the whole year for such work, a fact proved by the rarity with which trees now operated on fail to produce a full crop of fruit the following season. Gooseberries and Currants, being divested of foliage, may now be pruned. It is usual to defer the pruning of Gooseberries till spring, because birds are apt to make an onslaught on the buds, but if pruning be done now, and if afterwards the trees are splashed over with a mixture of soot and lime, with cow manure added to cause adhesiveness, the composition will not only be distasteful to birds, but only kill Lichen and Moss, which usually abound on neglected fruit bushes. When pruning, select the best-ripened wood for cuttings, which may be tied into bundles and heeled in to give profitable employment in bad weather in preparing them for insertion, which should be in rows 1 ft. apart and about 6 in. asunder in the rows. All the buds should be picked out of that part of the stem that is inserted in the ground, or there is a tendency to produce suckers, and each tree is always best when grown with only a single stem. Old plantations of all kinds of small fruits will repay any attention that can be afforded them at this season, such as the thinning out of useless naked wood, surface forking the ground, and afterwards giving it a good dressing of well-rotted manure, to be left on the surface to be washed in by the rains. Raspberries especially should annually have such a dressing. The season being so late, there are yet several kinds of Apples and Pears to be gathered, and as they are now in danger from severe frost they should be got in, ripe or unripe. Keep the fruit room well ventilated on every favourable opportunity till the fruit has become thoroughly dry, but afterwards preservative conditions are best assured by the maintenance of a somewhat confined atmosphere.

Vegetables.

Asparagus.—Tops of this will now have turned yellow, and should be removed; but, as in other cases of a similar nature, they ought never to be cut away whilst they have life in them. If there are any weeds on the beds, they should be cleared away. The beds should then have their winter dressing applied. This ought to consist of 3 in. of well rotten manure evenly spread over the surface. This not only has the effect of enriching the soil, by its fertilising properties being washed into the ground by the rains, but it also protects the crowns from frost; for, although a perfectly hardy plant, yet, like many others under a system of cultivation, it is better not to have the roots exposed to severe frost. If the alleys contain plenty of soil, an inch or two may be thrown over the manure; but the old method of sinking these two deep frequently did much injury to the roots, which grow persistently in a horizontal direction, often extending into the alleys, and when these were cut to such a depth as to throw a considerable portion of soil over the beds, the roots, of course, were more or less injured. The great mistake in the cultivation of this vegetable is in too close planting; two rows are quite enough for a 4-ft. bed, instead of three or four. There is nothing gained by close planting; when plenty of room is allowed, the heads, if they are not so numerous, are double the size, and the beds will last much longer in bearing condition.

Road Sand for Cuttings.—I have struck upwards of twelve dozen Geranium cuttings this year in a compost of three-fourths road sand and one-fourth ordinary garden mould; only three or four cuttings failed. Those I attribute more to having been put in late than to the compost; the others are looking splendid, and should really be repotted separately if I could afford room. The only objection I have to it (road sand) is, owing to its being so loose, the cuttings are very apt to fall out when the pots are moved. Mine are in pots, and yet for striking purposes the looseness is no doubt its great advantage, combined by its attracting and retaining the heat. For several years I have used road sand largely in growing Chrysanthemums, and have found it answer well, the plants presenting a most luxuriant appearance. I get mine from the gutters at the bottom of steep hills, it being carried there by heavy rains.—T. C., *Clifton*.

Worms in Pots.—I have noticed from time to time in GARDENING ILLUSTRATED lime-water recommended for this. I have tried it, but without success; but I have never seen a saccharine solution even spoken of. Some of your readers may not be aware that 1 oz. of cold water (the colder the better, as hot dissolves less) only dissolves about half a grain of lime; but by the addition of sugar it will dissolve about twelve times that quantity. Will any of your readers who may have tried this kindly state their results? or can any one say if lime-water so strong would kill the plants? I have tried

it myself, but I am not in a position to give an opinion, being A Novice in Horticulture.

Ants in Greenhouses.—I see many of our friends are troubled with ants, and so I used to be until I saw an article in this paper last year. The instructions were: Get your chemist to mix some arsenic with honey, and spread it on small pieces of glass and lay it in their runs. I have tried it, and cleared my greenhouse in one day. The glass was often covered with ants, but not one was to be seen after this treatment.

To Clean Garden Pots.—Rubbing in a basin of water or under a tap with a bit of pumicestone or broken brick, or broken garden pot, not too hard burnt, I have found to clean pots directly like new.—J. B.

House and Window Gardening.

Palms in Windows.—I have had a Palm called Kentia Canterburyana in my sitting-room window for over twelve months, and although it came in a very healthy condition from a nurseryman's greenhouse, it is now, if possible, even more healthy looking than when I had it. When I received the plant it was in a 5-in. pot, and had three leaves.

A good Window Palm (Kentia Canterburyana).

In spring I shifted it to a 7-in. pot, and now it has two other large and much more handsome leaves, and one more is just unfolding itself. It now has the appearance of the plant shown in our illustration. I used for potting ordinary garden soil free from worms, leaf-mould, Cocoa-nut fibre, coarse silver sand and bricks broken to the size of Horse Beans in about equal parts. I keep it slightly shaded from the sun, but give it all the light and air possible. After potting I gave no water till the soil was quite dry and the pot sounded hollow when rapped with the knuckles; then I placed the pot over head and ears in a bucket of soft water, and sponged the leaves with soap and water, afterwards washing them by pouring water on them for a few minutes through a fine-rosed watering-pot. I repeated this operation afterwards about once a week, except during hot weather, when the windows were kept open, when it required it twice. The pot is now getting full of roots, and I water about once a week. I shall not pot it any more, but when thoroughly pot-bound I shall give it soot water or liquid manure. I have used it as a centre-piece in a bay window, surrounding it with Begonias, Harrison's Musk, Golden-leaved Fuchsias, Mimuluses, Petunias, &c. These being now nearly over, I have some Cyclamen, Mignonette, and bulbs coming on to take their places. I have grown the following kinds of Palms also in windows, but they never gave me such credit as the one just alluded to: Areca Baueri, Chamærops Fortunei, C. humilis, Seaforthia elegans, Thrinax parviflora, Kentia australis, and Corypha australis. These species when grown in a greenhouse and with plenty of pot-room are of large size when fully developed, but by managing them in the way above described, their growth is kept within bounds.

Tuberous-rooted Begonias as Cut Flowers.—As these Begonias possess endless shades of crimson, carmine, red, pink, vermilion, and scarlet, there is a greater choice of tints among them than can be found in any other genus of flowers with which I am acquainted. In button-hole bouquets they are wonderfully effective; their stalks, however, are so slender, that each flower requires the support of a wire if it be liable to much shaking about. The best way is to cut a piece of stiff, fine wire about 4 in. long; turn one end like a very small fish-hook, and pass the other end down through the centre of the flower until the hook catches in the eye; then one turn of the wire around the stalk secures it in its place. Arranged with a few bits of Mignonette, the effect is both novel and satisfactory.—T. T.

Ivy in Dwelling Houses.—No plant does better in a sitting-room or hall than the common Ivy, or any of its green varieties. In countries where the cold is too great for the Ivy to flourish out-of-doors, it is much appreciated for house-culture. Being hardy and strong, it will bear ill treatment, but will pay for attention, and especial care should be taken not to make the rooms too hot for it; it will, however, prosper well in about the same amount of heat that the living occupants should have; that is, about 65° Fahr. Keep it cool and moist, but not too wet.

Hyacinths in Glasses.—These may be put in water now. The bulb should be placed, in the first instance, with its lower end not quite in contact with the water, which should be pure rain or pond water, and it need not be changed unless it becomes offensive. When the bulbs are in the glasses they should be set in a dark place for about a month, then gradually inured to the light, filling up the glasses as the water subsides. The bulbs will flower in the greatest perfection if placed in a cool, airy situation well exposed to sunlight, but it is usually desirable to place some at least in a warm place to accelerate the flowering period.—W. P.

Growing Hyacinths in Sponge.—Whilst reading a paper the other day I happened to see the following novel plan for cultivating Hyacinths in rooms, and it is one which I think ought to prove very pretty if carried out successfully. Having procured one of the large coarse sponges used by coachmen, I made several incisions in it and placed the bulbs in them. The whole was then put in a vase of water and a thimbleful of Rape seed was scattered over the surface of the sponge, which covered it entirely with a fine Moss-like mantle, adding greatly to its beauty and attractiveness. By using warm water they force readily and succeed admirably.—W. A. G.

VEGETABLES.

EXHIBITION POTATOES.

In answer to several correspondents I would advise any amateur cultivator who may desire to grow fine handsome Potatoes for exhibition not to limit himself severely in the number of kinds that he shall grow if he has space to place at their disposal. Some kinds will not do well in certain soils, others will. A couple of years' trial will soon settle this point, and when settled satisfactorily to the grower, some eighteen to twenty kinds should suffice, except where space will enable him to grow more largely, and exhibit in stronger classes. As a rule, however, few amateur growers can put together more than a dozen good sorts; and to get these it is necessary to have at least the numbers above named.

Taking twenty, therefore, as the maximum, I divide them into the customary divisions and class them thus: Six white Kidneys (a larger proportion of this section), are International, the finest, handsomest, and probably heaviest cropper of all the section. It produces a larger proportion of handsome samples than any other kind, and is now universally shown. It is a robust grower, a mid-season ripener, and wants quite 3-ft. intervals between the rows. In quality it is not first-rate, but from light soils is a capital winter main crop Potato. Woodstock Kidney, a yellow seedling of the International, both being the product of a cross between the Dawes' Matchless and old Cambridge Kidney, and raised by Mr. M. Fenn when at Woodstock, has growth and general character about the same as the other, but has an inveterate tendency to bloom and produce seed-balls. It is advisable to pick off the flowers to prevent the exhaustion to the plant that might otherwise result. The tubers are flattish, oval, of a brownish-white hue, first-class in quality and very handsome. Snowflake is a flattish, long-shaped tuber of American extraction, now too well known to need further reference. Covent Garden Perfection is own brother to Magnum Bonum, but earlier, the haulm growth dwarfer and quite distinct. The tubers are flattish, slightly tinted with pink. It is a capital garden Potato and of excellent quality. Advance, a seedling from an improved King of Potatoes; a robust grower, ready to lift in August; tubers flattish, square rather than oval, handsome and clear white, an immense cropper and first-class winter table Potato; very distinct. Last of the six I put Magnum Bonum, rather a coarse grower, it is true, but then it is so free from disease and produces such splendid crops of fine white Kidneys, that it would be a mistake to omit it. It should always have ample space. The tubers when about three-parts the usual size are best suited for the show table; and those shown so very largely at the Crystal Palace prove that it can produce plenty that are handsome. Of coloured Kidneys, rather a weak section, I class Mr. Bresee, a very handsome sort, of American origin; skin pale glossy red, an enormous cropper and of fair quality. This kind, being new, is yet dear, but will soon be found in all collections. American Purple, a long, very purple-hued tuber, very handsome, an immense cropper, and of capital quality. Beauty of Hebron, of the well known Early Rose family, but paler in colour, is of excellent quality and very handsome; and Garibaldi, a very red-skinned handsome Kidney, now almost universally shown. It is a good cropper, and of fair table quality. In white Rounds, I name Schoolmaster, a robust kind, tubers quite round, generally large, brownish-white and much netted; a capital Potato for general crop. Climax, the handsomest of all the American white Rounds, a large cropper and having a medium top. Porter's Excelsior: very prolific tubers, flattish, round, and very handsome indeed. Bedfont Prolific: tubers long, flattish, round, very white, handsome, good cropper; very distinct and excellent garden Potato; and Early Market: a first early garden kind, tubers handsome and of superior quality. Coloured Rounds give some handsome

kinds. Vicar of Lalcham: robust growth, tubers generally large and coming handsomest in soil of moderate richness; colour purple and very distinct. Grampian: robust spreading growth, great cropper, tubers pale red. Triumph: very early tubers, bright red; a great cropper. Radstock Beauty: very handsome, white mottled with red; and Blanchard, white mottled with purple. All these are first-class show kinds, and at present cannot be excelled. In selecting tubers at the lifting season, it is well to ignore mere bigness, and look for beauty allied to average size. A little experience will soon enable an intelligent amateur to understand the needed points in prize tubers. Do not wash when first lifted, but store in boxes in dry sawdust, and wash only when needed for exhibition. —A. D.

Leaf-mould.—No article of a fertilising description enters so largely into garden composts as leaf-mould in some form or other, perhaps as much because it is almost always procurable as that it is so useful for many purposes. Mould from tree leaves, or from a compound of leaves and litter, is of course referred to here, and not vegetable mould of any description, such as the decomposed refuse of garden crops, &c., which is a very different material, and, though a good manure for some purposes, is not a substitute for leaf-mould proper. With the assistance of leaf-mould and a little sand the gardener may reduce the heaviest and most uncompromising soil to a condition fit for any purpose. But he may also overdose his composts with it. It is quite certain that leaf-mould is often used to excess, and with no good results. It is one of the best root-producers that can be employed, and is chiefly useful on this account; but it is not a sustaining manure, and is only serviceable when mixed with soils of a substantial description. Hence it is generally used for mixing with maiden loam, whether turfy or otherwise; but for kitchen gardens or flower beds to which organic manures have been added for years it is of little value. In fact, there are many things, such as Lobelias, Geraniums, and other bedding plants, and vegetables, such as Turnips, Carrots, and Beet, &c., that never thrive successfully in a soil overladen with humus. It suits Potatoes and Peas, particularly if lime is given with it. Lettuce, Parsley, and Spinach, that grow quickly, delight in it, but it is not of great value to the Brassica tribe, unless in heavy soils. It is on the potting bench that leaf-mould is most constantly in request, being required for the majority of pot plants, and, in the absence of peat, indispensable for seed sowing. It is not advisable, however, to use it where bottom-heat is employed unless it is thoroughly decayed, and free from pieces of sticks or tree seeds, such as Oak or Beech mast. Wherever the latter is buried in heated beds or borders it generates fungi to an alarming extent. Beech leaves may be used for hotbeds, but they make the worst leaf-mould. Oak leaves are the best of all for every purpose, and next to them a general mixture is best, always keeping out Beech if practicable. Spent hotbeds generally supply the stock of leaf-mould; but one year's fermentation does not fit it for cultural purpose. It should be laid up in a heap and left till it is reduced to a fine black mould. The proportion of leaf-mould that should be employed for pot plants or beds depends upon the texture of the loam used. To our good but heavy loam here we add bulk for bulk for general purposes (not weight for weight), besides sand; this is not too much for the compost at the end of a year, by which time the mould has decayed considerably, but has the appearance still of a strong loam. Such plants as Cinerarias, Calceolarias, Pelargoniums, and Balsams thrive well in it, but with a less proportion of mould they root but slowly, and do not thrive. Light, sandy, or brown loams seldom require leaf-mould, but well-rotted cow manure may be given with advantage.—J. S.

THE GREAT REED.
(ARUNDO DONAX.)

When well grown this is admirably adapted for moist low-lying portions of the lawn or pleasure grounds, or for moderately sheltered situations in the vicinity of ornamental water. There are few hardy foliage plants that rival this in stately dignity after it becomes thoroughly established, either as planted alone, or when grouped with Pampas Grass, Chamærops humilis, or the larger Yuccas, all of which grow luxuriantly in our warm southern counties, and are invaluable to the horticulturist, enabling him to add charming variety of form to the garden landscape, and to tone down the glaring colours of our chromatic flower beds with forms that partake somewhat of semi-tropical grandeur. The plant we are now more particularly alluding to is rather difficult to establish in some localities, and on dry, barren, or sandy soils, it is as well to excavate 3 ft. or 4 ft. deep and fill in with a load or two of rich unctuous loam, in which it is generally found to thrive most luxuriantly if well supplied with water. Our illustration gives an excellent idea of the portly appearance assumed by this species. Among other places where this plant succeeds well in the south we may allude to the grand proportions which it attains at Syon House. It grows there from 9 ft. to 10 ft. high in dense masses, nearly as much in diameter, and forms a truly imposing object, none the less beautiful because uncommon in the majority of gardens. It is easily propagated by dividing large clumps, or the thick

The Great Reed (Arundo Donax).

cane-like stems may be cut down and thrown into any tank or pond where they will quickly emit growths from the latent axillary buds, and after these are rooted they may be grown on and established in positions where they are to remain. A. Donax variegata is a dwarfer growing plant, rarely exceeding 2 ft. or 3 ft. in height, each leaf being striped with creamy white. This variety succeeds in our warm sheltered gardens in the south, but it does not possess the stately appearance of the green-leaved species. The variegated form is, however, almost invaluable for the flower garden, either in the centres of beds grouped with the choicer hardy plants, or isolated on the turf. It should have a well drained position, a deep warm soil, and a slight protection over the roots in winter. In Spain and countries possessing a similar climate, the stems of this form of Arundo Donax attain a considerable height, and the leaves are broader and better variegated than with us.

ANSWERS TO QUERIES.

3385.—**Planting Vegetable Garden.**—Plant a good bed of Cabbages and Lettuces at once. Onions may be transplanted from the seed bed into other beds, 6 in. apart. Shallots may also be planted, but in most cases they will do as well in spring. The latter should be planted 6 in. apart in the rows and about 8 in. between the rows, drawing shallow drills and pressing the base of the bulbs firmly in them. The Ringleader Pea and Early Longpod Bean may be planted about the middle of next month on a warm dry site. Plant fruit trees of all kinds next month.—E. H.

3407.—**Trees for Screens.**—Form the screen with Poplars, with an outer fringe of Tamarix and Furze, with an occasional specimen of the Austrian Pine. In the pleasure grounds plant Thujopsis borealis, T. dolobrata, Cupressus Lawsoniana, C. nutkaensis, Cedrus libani, Cryptomeria elegans, Juniperus virginica, J. sabina, Picea Pinsapo, Pinus Douglasi, Retinospora pisifera, R. plumosa, common and Irish Yews, Evergreen Oaks, Planes, Limes, Scarlet Maple, Scarlet American Oak, Weeping Birch, Weeping Ash, Cerasus padus (Bird Cherry), Thorns, Laburnums, Spindle tree, Mountain Ash, Portugal Laurel; and when the shelter gets up, many of the best deciduous and evergreen shrubs will do if the soil is suitable.—E. H.

3397.—**The Polyanthus.**—Amongst Gold-laced Polyanthus, the old show section, the best are Exile, Lancer, Cheshire Favourite, George IV., Formosa, and President. These are always in the foreground, but are costly. We note, for instance, that they range in price from 2s. 6d. to 7s. 6d. each. They propagate slowly, and are somewhat tender in habit, wanting careful cultivation. Of self or fancy kinds there are the Bride (white), Viceroy (sulphur), superba (black), Conqueror (magenta-crimson), Meteor (maroon), and Cardinal (crimson-scarlet). These are also somewhat scarce, and range in price from 1s. 6d. to 5s. each. Really fine exhibition Polyanthus are yet scarce. Few mere border

kinds, though ever so showy there, can face the test of the show table. Propagation is often done with great success by dividing and re-potting as soon as the bloom is over; but we prefer the late autumn, say about this time, when the plant should be rubbed out, divided carefully with a knife, and the divided pieces be re-potted into smaller pots and placed in a cold frame, standing them on a thick bed of ashes, or else upon a trellis of woodwork raised a little from the floor of the frame. Give the plants all possible air in open weather during the winter, and the protection of a mat or two during severe weather.—A.

3396.—**Hollyhocks.**—Hollyhocks are propagated from cuttings chiefly in the spring, when strong roots throw up a number of shoots; these taken off with a small portion of the old wood soon strike freely in a little bottom heat. If put in now they would perhaps damp off. The mildew or fungus which affect the Hollyhock is best kept in check by often waterings and sprinklings. It is more the product of drought than of moisture. Rich, deep soil and plenty of moisture keep the plants growing and healthy. As to the names of a collection, that is not so easy to give, because there are so many colours in the Hollyhock, that a selection becomes much a matter of taste. Any trade grower will send a good one if a price is paid for good sorts.—A. D.

3387.—**Plants for Window Box.**—It is not too late to plant bulbs in a window box. Plant what you desire to grow at once, and surface with some double Daisies, Aubrietias, blue Forget-me-nots, or any dwarf early-blooming plants that will make the box green and gay in the spring. For summer a few scarlet Pelargoniums, Fuchsias, and Petunias behind blue Lobelias, Harrison's Musk, and dwarf Nasturtiums will make the box look gay. It is obvious that, owing to the limited root space, a window box must often be turned out and have fresh soil put into it, and, indeed, this should be done with every fresh planting if the plants are to thrive. If you do not care to plant bulbs now some half-dozen small shrubs may be planted, and a surface of Creeping Jenny or silvery Sedum.

3388.—**Carpet Plants.**—In a bed to be planted with carpet plants no taste can be worse than planting in regular rings or circles; it is stiff, formal, and without character. Run round the centre basket a series of small circles, or a chain pattern, or any plan that will give variety, using for the chain such a capital carpet plant as Sedum glaucum, and filling in the circles and half-circles with Golden Feather, Alternantheras, Sedum Lydium (green), Gibraltar Mint, Herniaria glabra, Mesembryanthemum, blue dwarf Lobelias, &c. If the rings are held of first importance, the plants may be Golden Feather, blue Lobelia compactum, Mesembryanthemum cordifolium variegatum, Sedums, grey and green, Mint, Herniaria, and the silvery Cerastium.

3392.—**Greenhouse Fuel.**—The great objection to coal for a greenhouse furnace with flue is that it creates a large amount of smoke and of course soot, thus choking the flue and greatly reducing the heat; still further, a coal fire needs more frequent stoking, as the coal will bake and get hollow. A mixture of fine coke and coal would perhaps suit you best. Of course the anthracite coal is not so objectionable on the score of smoke as other kinds. For an ordinary greenhouse flue there is danger in getting almost too fierce a degree of heat from coal solely, when once a good fire is established, the safest protection is found in a body of fire that burns slowly but surely, and does not need constant attention.—D.

3393.—**Creepers against Wire.**—The great obstruction to the growth of many creepers on wire-work is found in the tendrils refusing to adhere to the metal in the open air; further, in cold weather the draughts that circulate between the meshes of the wire seem much colder, and therefore more trying to vegetation than in the open. If the Virginian Creeper were carried up a wooden upright and along the top of the wirework, and so form a main stem, it would throw down every year a growth of several feet in length that would need no support. We find that Clematis Jackmani and its fellows will do well against wire, but these have to be cut down every year. Some of the robust climbing Roses do well; Canary Creepers will grow freely; Ivies will also, but not so kindly as against walls.—A. D.

3386.—**Flowers for Winter Blooming.**—It is useless to think of sowing seeds now to obtain plants to bloom in a greenhouse this winter. The best winter-blooming plants are Chinese Primulas; seed of these should be sown in May; Cyclamen seed sown in August to produce bloom in the second winter; Cineraria seed sown in June; all these need a heat constantly kept of from 50° to 60° to induce them to flower and keep them in bloom. All the plants are best kept in a cold frame during the summer, and put into the greenhouse in October. The range of plants that can be raised from seed to bloom in winter is limited.

3403.—**Seaweeds as Ornaments.**—I have found that the best way to preserve Seaweed is to place it between two pieces of blotting-paper, and lay on it some heavy weight, such as a book, &c. The blotting-paper must be changed every four or five days for three weeks or so. After the Seaweed is dry it may be gummed over on one side and placed on rather rough cardboard in the form of a circle, leaving a space in the centre for any appropriate text.—J. C., *Whitley*.

2990.—**Botanical Paper, &c.**—Having had many years' experience in drying plants, the plan I have found to answer best has been thus:—When collecting in the field I carry a book bound up with some porous paper, into which I put the plants as fast as I gather them. I allow them to remain in this book for about two days—this gives time for the first moisture to evaporate; they are simply strapped round, not heavily pressed. At the end of this time they are placed in the usual way, between sheets of blotting paper, gradually increasing the pressure; the advantages of this plan are, that they do not require the paper to be changed so often, and that the colours keep almost without changing. I find heavy pressure at first destroys the colour more or less. The plant when dry looks lifelike.—J. R. Neve, *Campden*.

3406.—**Climbers for Dwelling House.**—Ivies are the best climbling plants for a north aspect. Good kinds consist of Algeriensis, the common Irish, the large clouded white and Regner's broad-leaved kind. With these might be associated Pyrus japonica, Kerria japonica, and Jasminum nudiflorum, all of which will flower fairly well on a northern exposure. On the east side we would plant evergreen Roses, Ampelopsis Veitchi, so beautiful on account of the changing hue of its foliage in autumn, and such Clematises as Jackmani and lanuginosa candida. The western aspect we would devote to Gloire de Dijon, climbing Victor Verdier, and Cheshunt Hybrid Roses, Clematis Flammula and C. montana, clothing the lower portion with Euonymus radicans variegata; and the south side may be covered with Clematis lanuginosa nivea and C. rubella, Maréchal Niel and John Hopper Roses draping the lower part with Cotoneaster microphylla and golden variegated Euonymus. The Cotoneaster and the Euonymus are evergreen, and if another fine-leaved evergreen is wanted, take the Exmouth variety of Magnolia grandiflora. This should be planted on the south side, where it will freely produce its large pure white flowers, and the foliage is so handsome that it is worth planting on this account alone. The Camellia is seldom now used as a wall plant in the open air, but it is eminently adapted for the purpose, being quite hardy. It will succeed either in a north or east aspect, but must be planted in a good compost of peat and loam. When thus employed it forms a thick screen of verdure, beautiful at all times; and we should certainly devote a portion of the wall to this plant, as nothing could be more suitable for clothing the base of the walls, which, where strong growing climbers are employed generally get bare in time. Now is a good time to plant, stirring the soil deeply and well manuring it. The Camellias only should be left until July planting, just as the young wood gets firm. Regner's Ivy is the strongest growing variety.—J. C. B.

3381.—**Flowering Shrubs and Rock Plants.**—The following is a selection of beautiful hardy flowering shrubs: Hydrangea paniculata grandiflora; Berberis Darwini, Beali, aquifolium, and dulcis; Deutzia crenata fl.-pl. and scabra; Spiræa callosa, alba, and ariæfolia; Cytisus nigricans and purpurea; Pyrus japonica, grown in bush form; Clethra alnifolia, Viburnum plicatum, Weigela rosea, and Forsythia Fortunei. Flowering plants for rockwork may consist of Phlox Nelsoni and frondosa; Campanula pusilla, pulla, and garganica; Genista prostrata, Gaillardia bicolor, Thymus montanus albus, Silene alpestris, Dryas octopetala, Anemone apennina and pulsatilla, Primula denticulata and cortusoides amœna, Lithospermum prostratum, Polygonum vaccinifolium, Veronica incana, Arabis lucida variegata, Ramondia pyrenaica, Æthionema cordifolium, and any of the encrusted and Mossy Saxifrages, Sedums, and Houseleeks.—J. C. B.

3395.—**Scale on Orange Trees.**—Dissolve 4 oz. soft soap in 1 gallon of water; immerse the plant therein, allowing the solution to remain on a few days; then wash with clean water. From this time until April the scale will not increase, but the first week in that month dip again in soft soap, and should any signs of the insect show itself repeat the operation. If the plants are root-bound shift in June, and if they do not appear to need repotting top-dress with concentrated manure, and encourage them to make free growth. Scale cannot make way on healthy-growing plants; it is only when they are starved or in a bad condition generally that this pest gets the upper hand.—C.

3409.—**Oleander not Thriving.**—A course of ill-treatment has brought the plant into an unhealthy state. The leaves turn yellow because the roots are either torpid or partly decayed. You were very wrong in shifting the Oleander at this time of the year; remember for the future never to re-pot plants of woody growth after May, so that the pots get full of roots by the autumn, at which time the supplies of water should be somewhat diminished, keeping the plant on the side of dryness throughout the winter. Keep your plant now without water until the soil has quiet dried out, and then give just enough water to permeate the soil, at the same time thoroughly cleansing the foliage. In February cut back the shoots to two-thirds of their length, watering with great care until fresh shoots appear. Then turn the plant out of the pot when the soil is dry; shake away as much of the old mould as possible, and re-pot in free soil in as small a pot as the roots can be crammed into. Thus treated, the roots will come into a healthy state, and good growth will follow. When the pot gets full of roots and the weather is hot, plenty of water may be given, but up to that period water only when the soil is dry.—J. C.

3384.—**Indian Pinks.**—Indian Pinks will do admirably round a bed of Carnations, &c., and be in admirable keeping. The plants should stand the winter in a sheltered place, but it is not possible to assure that they will do so, as offtimes rains and white frosts do more harm than very severe weather.—A.

3401.—**Gnat Bites.**—A spoonful of sal volatile in half a wineglass of water and as much carbonate of soda as can be placed on a sixpence; mix together, and well bathe the bites frequently.—S. C.

3412.—**Poultry Manure.**—You might use poultry manure with advantage if well mixed with a heap of garden refuse, the accumulations of the previous winter. Mix well, turning several times before finally making the bed or heap. After the Marrows are off the material will do well as manure for Potatoes or other roots. Employed in this way poultry manure is more valuable and safer than when applied to crops in a raw state.—D.

3413.—**Briza maxima.**—One of the very prettiest of all ornamental Grasses is the Agrostis nebulosa. It is as easily grown as the Briza, but is far more elegant and graceful. Seed sown in pots in March will grow well, but the little plants should be thinned out somewhat. A fresh sowing may be made in May. When quite ripe and cut dry it makes singularly pleasing bunches for the decoration of rooms, the fine grassy fibres being each furnished with tiny knobs or seed-pods that do not fall.—A. D.

—— Sow the following ornamental Grasses or some of them: Agrostis argentea, A. nebulosa, Briza gracilis, Eragrostis elegans, Lagurus ovatus, and Isolepis gracilis.—E. H.

3398.—**The Cardinal flower.**—The roots of the Lobelia cardinalis should be treated just as if left in the open ground all the winter, where they would keep well but for the frost. Lift and shake off the greater portion of the soil and place them thickly in shallow boxes, fill in with fine ashes, and place the boxes on the floor of a greenhouse or in a cellar. The roots must not get dry, or be kept wet; of course the stems are cut down before the plants are lifted.—D.

3399.—**Cerastium Edgings.**—Old edgings of the Cerastium get brown at the bottom; it is, therefore, a good plan to shear them off closely early in the spring if wanted for a summer effect. The best plan, however, is to put in during the summer a large quantity of cuttings, and these will make strong fresh plants to put out the succeeding spring.—D.

3391.—**Rose Hips.**—It has often been proved that Hips, Haws, and mountain Ash berries have preserved colour and freshness well if buried in the soil lightly and

where moderately dry, but not absolutely so. They do not shrivel or decay so treated for a long time.—A.

—— Rose hips may be kept a considerable time when cut with a few inches of wood attached, placed in a pan of water that contains charcoal enough to keep it sweet. Discolouration may be improved by the use of a little red paint.—H.

3408.—**Flowers and Shrubs in Greenhouse Killed by Tar Varnish.**—Scrape off as much of the tar varnish as possible, and paint the pipes with lamp-black and oil, leaving a little ventilation on the house night and day till the smell passes away.—E. H.

3271.—**Wintering Chrysanthemum Halleri.**—Take off the young shoots with about three joints and insert them in sandy soil in a 4½-in. pot. They will strike root freely at the present time, and may be kept in a light window in the dwelling.—C.

3256.—**Plants for a Shady Border.**—Primroses, Polyanthus, Saxifraga umbrosa, Daffodils, Snowdrops, Christmas Roses, Myosotis dissitiflora and sylvatica and its white variety, bedding Violas and Pansies, Arabis albida, Aubrietia græca and purpurea, and Silene pendula.—B.

3273.—**Plants for a Cool Greenhouse.**—We cannot help you to a list of hardy flowers for winter blooming, but another season you should in the spring procure a few young Primulas, Cyclamens, and Cinerarias; also in the autumn (now is a good time) pot some flowering bulbs, Primroses and Polyanthus, which would be gay in early spring.—J. C. B.

3390.—**Bush Gooseberry and Currant Trees.**—First cut off any branches that hang on the ground; then carefully thin out the other branches where they cross each other, opening out the centre at the same time. Do not prune too severely, or you will cut off the fruit.—E. H.

3412.—**Poultry Manure.**—Poultry manure as it comes from the fowl house is too strong for everything. Mix it largely with refuse or soil, road cleanings and scrapings, parings and edgings of walks, &c.

3404.—**Daisies on Lawns.**—The simplest method of eradicating Daisies from lawns is to turn on a lot of children, with a woman or two to look after them, providing each one with a plain, simple implement for extracting the roots. Do the work at once, and top-dress with soot and wood ashes, or else wait till spring.

3388.—**Early Tomatoes.**—To produce ripe Tomatoes in January or February, the plants should be in existence now either in the shape of cuttings or seedlings, and they should be grown on through the autumn and till the days lengthen in a night temperature of not less than 55°, close to the glass. As the days lengthen after Christmas they will enjoy more heat. The best early sorts are Orangefield, Earley's Defiance, and Criterion.—E. H.

3402.—**Pruning Gloire de Bordeaux Rose.**—Cut back the shoots in March to about two-thirds of their length. Hard pruning does not do for these vigorous growers, which generally require two or three years to bring them into bloom-bearing condition.—J. C. B.

3411.—**Height of Geraniums.**—There is not much difference in a general way between Madame Vaucher and Christine, both of which are dwarf and compact. Wonderful, runs somewhat taller, and Lucius is perhaps rather the strongest grower of the four.—J.

3388.—**Carpet Plants.**—In the centre we would place a fine-leaved plant, such as Polemonium cœruleum or Chamæpeuce diacantha, following up with blue Lobelia, Golden Feather, Cerastium Biebersteini (white leaf), Stellaria aurea (gold and green), Alternanthera amabilis, Echeveria secunda glauca, and Sedum acre aureum.—B.

3382.—**Aristolochia.**—A light, free soil should suit this creeper, but a little manure should be added thereto if very poor. As the plant in question had made no start, take it up, shake away all the old soil, spread the roots carefully out, pressing the mould firmly round them. Mulch in the spring with manure, and water in dry weather.—C. B.

3400.—**Rose of Sharon under Trees.**—This will thrive under trees where the shade is not too dense.—C.

3393.—**Hardy Climbers for Wire Trellis.**—Neither the Ivy nor the Virginian Creeper take kindly to a wire trellis. We would plant any of the Evergreen Roses or Gloire de Dijon and Cheshunt Hybrid, associating with them blue and white-flowered Clematis. A good evergreen is Cotoneaster microphylla, which grows freely and bears bright berries in the winter.—J. C.

3290.—**Gentians not Flowering.**—There is a slight, but misleading, mistake in my answer to this, whether made by the printer or myself I know not. Instead of "it should have turf mould, with sand and some stones stuck between the plants," read "it should have turf mould mixed with sand, and some stones stuck between the plants."—S. F. M. L.

3410.—**Fungus on a Lawn.**—Give the space affected a good dressing of lime and soot in equal parts, and either water it in or leave the rain to do it. If one dressing does not suffice, do it a second time.—E. H.

3394.—**Gum Cistus from Seed.**—Much depends upon the culture in good free soil. A fair-sized specimen may be obtained the third year from seed. We would order Cistus ladaniferous maculatus.—B.

Although the following questions are answered by the Editor, he will be obliged to any of our readers who may think well to answer them according to their experience.

3490.—**To Grow Belladonna Lilies.**—*Torment.*—If the soil be stiff, it should be well drained. Choose a situation such as that on the south side of a house or wall, take out the whole of the soil to the depth of 3 ft. or so, and about 6 in. of broken bricks should then be placed in the bottom. Over this some half-rotten manure should be scattered to keep the drainage open, and to form a supply of rich food for the plants to feed on. If the natural soil is not good, some fresh sandy mellow loam should be substituted or added. Should the soil be at all stiff, a few barrow-loads of thoroughly decomposed leaf soil and one or two of sharp sand should be mixed with it. Having trod this tolerably firm, the bulbs should be planted singly, or in threes if plentiful and it is desired to furnish the border quickly. In the latter case each clump should be about 1 ft. apart, and if the border is of such a width as to require a double row, the plants in the second should be alternate with those in the first. In planting, a handful or so of sharp sand should be placed round the bulbs to keep them from rotting. If planted now, or at any time during the winter, it will be necessary to protect the bulbs from severe weather by applying a good coating of half-rotten leaves, Cocoa-nut fibre, or some other unobjectionable-looking material, so as to form a neat-looking and safe kind of protection against severe frosts. Nothing further will remain to be done till the plants begin to push forth their new leaves, which they do rather early in the spring, and upon the freedom with which they send forth these during the summer the abundance or otherwise of bloom in the autumn in a great measure depends. When once they get fairly into growth they should have plenty of assistance during the dry weather by giving them an occasional soaking with clear water, and from time to time with liquid manure, as it may be required. The object that must be aimed at is a full and free development of leaf growth, and, this accomplished, an abundance of flowers is sure to follow. As soon as the foliage ripens off, it should be carefully removed, and the border cleaned and neatly raked over before the blooms begin to protrude through the soil, or they will become injured.

3491.—**Plants for Outside Window.**—What plants will keep their foliage through the winter outside a window?—HOMBRE. [Laurustinus, Laurels, Rhododendrons, Thujas, Retinosporas, and similar shrubs. In summer plunge them in the open ground, and they will be available for several years.]

3492.—**Variegated Stonecrop.**—How can I keep plants of variegated Stonecrop, which have been in pots, out-of-doors? since taking them in the leaves are falling. What treatment do they require? ought they to be repotted?—FOREST GATE. [Put them out-of-doors again; they will do no good in a room where they cannot get plenty of pure air. Plant them out or plunge the pots in ashes or soil.]

3493.—**Dividing Strawberries.**—*J. C.*—Old Strawberry roots divided and planted in good soil will fruit very well, but young runners are much better.

3494.—**Phlox Drummondi and Dianthus Heddewigi.**—I have had the above flowering beautifully all summer and autumn. Will these plants stand the winter and flower next year? or should I destroy them and sow again in spring?—YORKSHIRE. [Sow again in spring.]

3495.—**Heating a Frame.**—I have a frame 10 ft. by 6 ft., 4 ft. high at back and 2 ft. front, which I want to heat for the winter; would prefer fire-heat, not lamp. I have all kinds of plants to put in when I can settle the bottom-heat. What would you advise me to do?—AMATEUR, *Gloucester.* [Have a brick flue or a flue of earthenware pipes, or, better still, a small boiler and hot-water pipes.]

3496.—**Begonia Frœbeli.**—I have a root of this; am I to start it now or in spring.—CONTRARY MARY. [In spring.]

3497.—**Potting Primulas and Cineraries.**—*Hombre.*—Well drain the pots; disturb the roots as little as possible, and fill up with turfy loam and leaf-mould in equal proportions.

3498.—**Portulacas from Seed.**—*Hombre.*—It is of no use to sow the seed now. Sow in March in heat, or in April or May in the open ground.

3499.—**Strawberries Dying.**—I have planted 200 plants in an open bed (south-east aspect), out of which only ten have struck; the others have all perished. What is the reason of this misfortune?—NEOPHYTE. [If the runners were rootless when you planted them, but little better results could be expected. If you had pegged the runners down to the ground or put them in pots, and have let them got well rooted before separating them from the parent plants, you would not have lost ten out of the 200. If you had only consulted back numbers of GARDENING, your misfortune would not have occurred.]

3500.—**Plants among Tulips.**—I have a bed in my garden in which I have planted a quantity of early Tulips 6 in. apart. Is there anything I can put between them without crowding to make the bed look gay when their bloom will be over?—W. [Plant some young, healthy Pansies or Violas. They will give a display in summer and autumn.]

3501.—**Tomatoes Rotting.**—*E. W. P.*—Probably they were affected with the disease which has been prevalent among Tomatoes of late years. It is similar to the Potato disease. As yet we know of no certain cure or preventive.

3502.—**Deformed Fuchsia Bloom.**—*Benj. W. Green, Hawarden.*—No doubt the bloom-bud was on the cutting when you put it in the soil and the check thus given prevented proper development.

3503.—**Barberries.**—*K. K.*—The specimen sent is the common Barberry. The fruit may be preserved for garnishing; it also makes excellent jelly.

3504.—**Foxgloves and Snapdragons from Seeds.**—*S. B.*—Sow in May or June in boxes or in the open ground. Prick out when large enough, and transplant into open borders in August or September. They will flower the following year.

3505.—**Names of Soils.**—What are loam and peat? and where are they to be found?—FOREST GATE. [Loam generally used for gardening purposes is the top spit of a pasture. Peat is the top spit dug from heath land. Consult our advertisement columns.]

3506.—**Making an Asparagus Bed.**—*M. M. N.*—Dig up the ground roughly, working into it a liberal quantity of rotten stable manure, and let it remain till March. Before that time directions for planting will no doubt be given in GARDENING.

3507.—**Sheltering Grape Vines.**—Can you suggest a cheap and simple plan for sheltering Vines under glass without incurring the expense of a Vinery? I have two Vines against a south wall 11 ft. high, and occupying length of 23 ft., but find their ever bearing fruit fit for use quite hopeless.—C. S. [Have a glass case about 2 ft. wide from the wall. They are cheap and effectual. The light must be made to slide, so that the Vines can be got at. In winter the lights can be used for protecting salading, &c., and be put over the Vines in spring.]

3508.—**Keeping Lilies through the Winter.**—*L. T.*—Plunge the pots in ashes up to their rims in your cold frame. They will need no water till growth commences.

3509.—**Offsets on Auriculas.**—*E. S. H.*—These should be taken off in July when the plants have done flowering.

3510.—**Alternantheras.**—*Ferncastle.*—There are a dozen or more varieties of Alternanthera, all of which are tender and require a hothouse for their protection in winter and for their propagation in spring.

3511.—**Yellow Strawberry Leaves.**—*Vicar.*—The leaves of Strawberries in pots intended for forcing are sure to turn yellow at this time of year. Keep them in a frame, and water them when they get very dry. Introduce them to the forcing house about February, unless you want them very early. Remove all dead leaves occasionally.

3512.—**Narrow-leaved Dracæna.**—Will you kindly tell me the proper soil required for the narrow-leaved hardy Dracæna, and its treatment indoors in winter? Also will the leaves grow again down the stem in spring where they are now bare?—A LEARNER. [Let the plant remain till spring, then cut it down to within 1 in. of the soil. It will emit several shoots if placed in a warm greenhouse or window, the strongest one of which may be left and the others removed. The top which is cut off will strike root if placed in a small pot of sandy soil, made firm, and plunged in a little bottom-heat with a bell-glass over it. Cut the top just below the lower leaves. The piece of stem remaining, if cut into inch lengths and put in sandy soil in bottom heat, will make plants.]

3513.—**Wintering Lobelias.**—I cut my Lobelias down to within 2 in. of the root about a fortnight since, and they have sprouted and made very healthy and bushy plants. Can I save them through the winter without heat?—F. H. B. [Yes, if you keep frost and damp from them.]

3514.—**Fritillaria meleagris in Pots.**—*E. F. S.*—Put five bulbs in a 6-in. pot, using light sandy soil. Plunge the pots in a cold frame until the plants show signs of flowering; then wash the pots and move them indoors.

3515.—**Wintering Young Fuchsias.**—A few weeks ago I purchased cuttings of Fuchsias, and they seem to have started to grow. As they are very juicy and tender, will you tell me the best way of keeping them through the winter in a greenhouse from which frost is excluded, but which cannot be kept at more than a low temperature in very cold weather?—W. W. GRANGER. [Keep them in a light, airy position, and also keep them rather dry at the roots, and the tops free from damp. The wood will then harden, and they will be safe.]

3516.—**Bottom-heat for Cucumbers.**—Our Cucumber house, which is a span-roof 33 ft. by 12 ft., with a bed down each side, is heated by means of a flue and two rows of 4-in. hot-water pipes; the flue gives bottom heat, and the pipes top-heat; the beds rest on timber 4 in. or 5 in. above the flue. I wish to know if it would not be better and give far more bottom-heat if the timber was taken out, and about 2 in. or 3 in. of sand laid on the top of the flue on which to make the beds?—G. G. P. [If the flue is enclosed your best way would be to have a tank 2 in. or 2 in. deep made of zinc, tin, or earthenware, which, if kept filled with water, will give off regular moist heat. The slabs may remain, or slates may be substituted for them.]

3517.—**Belladonna Lilies.**—Can I safely leave bulbs of Amaryllis Belladonna blanda in a warm border out-of-doors during the winter? Also, does this Lily do best under glass in pots or in an open border?—M. C. [Cover the bulbs with 2 in. or 3 in. of ashes, and they will be all the better for being left in the ground. Belladonna Lilies flower well in pots for one year, but unless well cultivated afterwards they seldom flower satisfactorily.]

3518.—**Wintering Coleus.**—*G. G. P.*—Keep them on a dry shelf in a temperature of not less than 55° or 60°.

QUERIES.

3519.—**Renovating Pear Tree.**—I have a fine healthy Louise Bonne Pear tree; it may be thirty years old. The pruning has been neglected for years. It has made plenty of wood and blossoms freely. I have not had more than a peck of fruit in three years. The ground is 4 ft. deep with a clay bottom. How can I make it fruitful?—A. T.

3520.—**Camellias in Gloucestershire.**—Can some one acquainted with the growth of Camellias tell me whether they would be likely to grow out-of-doors in Gloucestershire? The situation is a small garden walled round, open to the west, but with no large amount of sun in the winter.—A CONSTANT SUBSCRIBER.

3521.—**Potatoes for Autumn Planting.**—I should be glad to know if either of the following Potatoes would answer for autumn planting, viz., Magnum Bonum, Bresee's Prolific, or Snowflake? and if not, what are the best kinds? also any hints as to mode of planting?—T. G. G.

3522.—**Woodlice in Pears.**—Your correspondent "B. S." speaks of the good qualities of the Doyenne Boussock Pear, and mentions the weight of three which were gathered from one stalk, viz., 1½ lb. I can also give proof of its excellent qualities, not the least of which is its bearing, not only in weight, but in quantity. I have just gathered mine, and seeing his ("B. S.") communication in GARDENING of October 9, I weighed three off one stalk, when to my surprise they drew down 2½ lb., but I could produce three of greater weight from different stems. I was surprised to find some with holes in them in which were woodlice. Can it be that they ate the holes, or only found shelter in them after the holes were made, presumably by hail? I should like to rid the trees of them. Will any correspondent be kind enough to give a remedy?—R. D.

3523.—**Rent of Garden.**—What rent ought I to pay per year to get a fair return for a garden consisting of about ¾ of an acre, walled in all round 8 ft. high, and planted mostly with Apples and Pears trained inside walls, three moderate sized frames, Vinery about 20 ft. long, and 10 ft. wide, planted with Black Hamburgh and Muscat Grapes, a small greenhouse 12 ft. by 6 ft.; the one heating apparatus heats both houses?—A NOVICE.

3524.—**Plants for Wet Soil.**—Will some reader inform me what are the best plants to put on a piece of ground which is flooded two or three times during the season?

the soil is good and not heavy. Would Parsnips do well? if so, what sort would be best for heavy cropping?—Nemo.

3525.—**Unproductive Garden.**—Will any reader kindly tell me the reason my garden does not grow good Potatoes? I planted Ashleaf Kidneys which were fine healthy sets, using guano, salt, and soot mixed together. I likewise planted some red Potatoes and Champions. When the tops died off I dug them up, and was surprised to find the tubers of them no larger than marbles, and very green. I earthed them well up and kept the ground clear of weeds whilst they were growing. The soil is a fine light loam, about 18 in. deep, with sandy bottom. It has had very little manure on it, because it is difficult to get here. I have also a bed of Parsnips and Leeks which are doing no good.—H. D. H. D.

3526.—**Grafting Potato.**—One of the witnesses before the Select Committee on the Potato crop mentions grafting Potatoes for producing varieties. Can any correspondent explain how this can be done? Is it done by grafts on the stems of the Potato? or by cutting two tubers of different kinds and placing the cut sides together? or how otherwise?—Querist.

3527.—**Large Strawberry.**—Some years ago I had a very large variety of Strawberry, which, I think, fruited late in the season. The leaves of the plant were thick and downy, and the berries were almost as large as a duck's head, but were hollow in the middle. I have made several local inquiries for this variety, but cannot ascertain its name or where to be obtained. Can any one help me?—F. H. Earle.

3528.—**Rose not Flowering.**—I have a half standard Gloire de Dijon Rose in my garden which has been planted two years and makes magnificent foliage, but never shows a single bud. Can any reader give the reason of its not flowering?—J. R. Y.

3529.—**Protecting Roses.**—I should be glad if any one could tell me what is the best plan to preserve through the winter the buds of Roses that have just begun to shoot, or have shot about 1 in. Would Fern do? or would it not be likely to weigh down and break off the tender shoot in bad weather?—E. C.

3530.—**Christmas Roses.**—Having a great fondness for Christmas Roses, I should be thankful for any information which will enable me to succeed in growing fine plants. On two occasions I procured plants from a nursery, and although they are certainly living, they are almost the same size as when I planted them twelve months ago. A suggestion offered to me a short time since was to put the plant into a bed by itself and leave it undisturbed, but other suggestions will be thankfully received.—G. B.

3531.—**Killing Tree Stumps.**—I have some Wych Elm and Sycamore stumps cut down as low as possible which are sprouting. How can I destroy them in the ground as they are?—J. R.

3532.—**Tin Boxes for Violets.**—Where can these be obtained?—M. L. B.

3533.—**Fungus in Vine Border.**—My Vines never yield a crop of Grapes. I have had the border examined, and find the soil is full of fungus. Will some one give me a remedy?—S. M. D.

3534.—**Watercresses in Frames.**—Will some reader inform me how to grow Watercresses in a frame through the winter?—F. C.

3535.—**Sea Sand for Ferns.**—Can anyone tell me if sea sand is of any use to mix with mould for Ferns?—G. H. M.

3536.—**Guernsey Lily After Flowering.**—Can any one say how the Guernsey Lily ought to be treated after it has flowered, so as to bring out the leaves? Is it possible to get it to bloom next season? It is at present in a sitting-room.—J. B. G.

3537.—**Hardy Perennials.**—I have a room over dwelling house, south-east light. Can I raise plants sown in pans (earthenware) that will bloom next season? if so, what kind of soil is necessary? and the most suitable kinds for garden about 10 yards square?—Neophyte.

POULTRY.

Fowl Keeping in Small Spaces.—On reading "North Yorkshire's" article on this subject I was considerably surprised to find him recommending Brahmas for small spaces. Of all the fowls for confined spaces, Brahmas and Cochins I believe to be the very worst which could be selected if eggs are any object. They are perpetually wanting to sit, and apparently the more confined they are the worse this peculiarity gets. I should advise "North Yorkshire" to get some black Hamburghs, try them for twelve months, and then give his opinion. We have nine hens and one cock. The hens lay on an average 150 eggs each per annum, and they get nothing in the way of food except the scraps from a family of ten people and sixpennyworth of wheat per week. They are far cleaner than Brahmas, in better feather, and in better health, and we have had for months in succession an average of 45 eggs per week at a cost of sixpence. A neighbour who has over 50 hens of various breeds now obtains (October) about two eggs per week. We have two or more daily. They get sadly neglected, left entirely to the servant, and are absolutely no trouble. Not one has wanted to set throughout the year, and we come to the conclusion that they pay exceedingly well. We have tried Brahmas, but have had quite enough of them, and do not intend to try again. When confined they are exceedingly dirty, troublesome, and an expensive luxury.—T. F.

Fowls Unhealthy.—I have some young Brahmas, one or two of which seem to mope about, and set their backs up as though they are cold, but yet seem to feed pretty well. I should like to know if any one could tell me what is the matter with them, and a remedy also.—Nemo.

Hens Laying in Winter.—I have two fine Brahma hens which I am desirous of keeping through the winter, and should be glad of any information as to how I can best induce them to lay during that time.—T. G. G.

Hatching Chickens with Hot Water.—*P. J. W.*—"Hydro-Incubation." By Thomas Christy. Price 1s. Christy & Co., 155, Fenchurch Street, London, E.C.

BEES.

Keeping Bees through the Winter.—In reply to the queries of "A Weaver," 1st, as regards the weight a hive of bees should be to have sufficient food to last through the winter, it first of all depends upon the size of hive and quantity of bees in it, a large quantity of bees needing more food than a small one. A good hive of bees must have 15 lb. net weight of food stored up to be safe for the winter and up to the end of March. "A Weaver" must find out as near as possible what weight the hive, bees, comb, brood (if any), and pollen are collectively, and if a large and strong hive, he must feed until they are 15 lb. heavier. An 18-in. flat top straw hive and bees without floor-board weighs about 15 lb. 2nd. The way I prefer to feed is, put an eke under the hive about 4 in. deep and of the same diameter as the hive, and put a feeding-pan with a wooden float in it, perforated with small holes, on the floor-board inside, and fill it with syrup. My feeders are 10 in. diameter by 3 in. deep, and made of zinc, and will hold 2 quarts of syrup, which the bees take in one night. To make the syrup, put to every pound of sugar one pint of water, and boil about three minutes; stir while boiling until the sugar dissolves. "A Weaver" must feed his bees at once, as they won't take it if the weather gets much colder. Feeding bees ought to be over by the present time. Some bee keepers prefer to feed on the top of the hive through the hole in the crown in preference to the bottom, but I prefer the bottom, and find the bees take it up longer from the bottom than the top when the weather is cold. Give it them with the chill taken off. If the above instructions are observed, early swarms may be depended upon if the queens are young ones and the hives are kept wrapped well up.

Supers.—"J. B. W.," does not mention in his query the time of year he put the supers on; most likely he was too late (unless he lives in a heather country). Near London July would be as late as he could expect them to do much good. Glass supers should be covered with a cap of cloth, but wooden hexagonal supers with small window I have always found to work best; the bees enter them more readily, and by having two sliding bars in the top which can be withdrawn when super is full, you can place one on the other, and secure a larger harvest. No ventilating hole is wanted; the bees would be sure to stop it up. Use the second hive as a cover only.—J. W

AQUARIA.

Management of Aquarium.—*Pisces.*—If you refer to the back numbers of Gardening you will find plenty of the kind of information you require.

Cement for Glass Tanks.—Take of red lead two parts, letharge one part, and a sufficient quantity of gold size to make a stiff paste. Before using, the frame must be scraped clean and be perfectly dry. The cement must be applied in a thick layer; the glass must be pressed into it firmly, so as to form its own bed in the cement, which should adhere so closely as to exclude all air bubbles. The glass and cement ought to be left for two days to harden.—G. P. Dale.

Fish for Aquarium.—Will some one give me a few hints respecting my aquarium? It holds about twenty buckets of rain water, overflowing when raining. It is in a dark corner, covered with Maiden-hair Ferns, on a shelf. I have three gold fish at present; could I keep more in this tank? and what sort of plants are best to put in the tank?—J. S.

HOME PETS.

Worms in Dogs.—In No. 72 of Gardening I saw a recipe for worms in dogs, but I cannot agree with it; being a great lover of dogs I have kept them of all sorts and sizes, from a toy-terrier to a St. Bernard. I make a point to get them not more than six weeks old, and I manage as follows:—For a puppy of whatever sort, until six months old, I omit the evening meal; the following morning I give a pill made of equal parts of Kamala powder and Areca Nut, the latter freshly ground. I weigh the mixture and give two grains to every pound weight of the dog; but no dog, be he ever so large, will require more than two drachms. I make it into a pill with flour, place it well back on the tongue, and I never have any trouble with the pups taking it. In an hour I give from a teaspoonful to two tablespoonfuls of olive oil, according to the size of the dog; repeat this every fourth or even third day until four doses have been given. This remedy is quite harmless and thoroughly effectual. Ground glass is, to say the least, dangerous, and may act in a very different way to that intended. The turpentine is apt to inflame the kidneys and cause great unnecessary suffering to our pets. I omitted to say, on no account give the dog oil before giving the pills, and let the stomach be, if possible, quite empty; any one can do this by keeping the dog a sufficient time without food according to age. The great secret in getting rid of worms is perseverance. Every three or six months dose them until two years old, then once in nine or twelve months will do according to their feeding, whether raw or boiled food. I always boil mine, and my dogs do not know the taste of raw meat. A tablespoonful of lime water in boiled milk to a puppy till nine months old will greatly tend to keep down worms.—Fannycums.

Baths for Cage Birds.—Let them have an occasional bath during the moulting season; it will do them no harm.

Canaries for Exhibition.—There are over twenty classes for canaries in a good show. "Amateur's" best plan would be to attend some first-class exhibition. He could then decide on which class or classes he would like to compete in, but if he is an amateur, unless he has plenty of time, money, and above all more than Job's patience, I, as an old hand, should not advise breeding exhibition birds.—J. F.

Food for Canaries.—Bread mixed with egg will not hurt canaries if "A Subscriber" takes care that the mixture does not go sour before they eat it.—J. F.

Pairing Canaries for Breeding.—March is the best time to pair canaries for breeding.—Canary.

—— The end of February is the best time to commence mating the birds you wish to breed from. I shall be happy to give further particulars if necessary.—J. H.

THE HOUSEHOLD.

THREE BREAKFAST DISHES.

Stewed Tomatoes.—Take ten or twelve ripe Tomatoes, put them into a small stew-pan with a pat of butter and a little pepper and salt. Let them stew gently until tender. Serve them with their own juice in a deep dish, accompanied with a round of buttered toast.

Puree of Tomatoes.—Chop an Onion finely, stew it with a pat of butter until quite tender, but do not let it take colour; then, having laid this on one side, take six or eight Tomatoes and stew them in a little butter. When tender, rub them through a sieve, put the pulp and juice into a saucepan with the Onion, pepper and salt to taste, a pat of butter, a dessert-spoonful of chopped Parsley, and a very little chopped Thyme (two or three leaves are enough); let these ingredients simmer together for a few minutes in an uncovered saucepan, then poach four eggs, place them in a hot dish, and pour the purée round them. N.B.—Thyme has a very powerful taste, and some may prefer the Parsley without it.

Stuffed Tomatoes.—Take eight or ten Tomatoes thoroughly ripe, wipe them carefully, and take off the stalks. Cut the tops off, and with a small spoon carefully scoop out the insides without breaking the skin. Have ready a chopped Onion stewed tender in butter. Then rub the pulp of the Tomatoes through a fine sieve, put it into a stewpan with the Onion, a little chopped Thyme and Parsley, pepper and salt, and a tablespoonful of boiled bacon and the same quantity of any cooked meat, both finely minced; add to these a little butter, and let the whole simmer for a short time until it thickens; then fill the Tomatoes with the mixture, cover them with some well-browned bread-crumbs, put them into a dripping tin which has been rubbed with a little butter, and let them remain in the oven until thoroughly heated. Serve on a hot dish.—N.

Uses of Borage.—Can any one advise me how to best make use of Borage? I have a quantity in my garden, and should be glad to use it as a cure for dropsy in the form of tea or anyhow. Should it be cut whilst in flower and dried, or how?—H. P. T.

Celery a Wholesome and Nutritious Vegetable.—Wash and prepare one or two heads of Celery, cut in small pieces, boil in sufficient water to cover; when quite tender thicken liquor with milk, flour, and butter (the three latter previously mixed); simmer for few minutes, then pepper and salt to taste.—Julia.

TULIPS.

THE common Tulip (Tulipa Gesneriana) is a native of the East, and is the parent of the numerous brilliant varieties which are used for outdoor culture. T. suaveolens and T. præcox are natives of the south of Europe, and are the parents of the kinds used for forcing in pots, including the well-known Duc Van Thol, which is sometimes considered to be a distinct species, but which is really a form of T. suaveolens. Many of the species or wild Tulips, from which so many fine varieties have been raised, are well worth growing in hardy plant borders. Greig's Tulip (Tulipa Greigi), for example, figured in GARDENING, page 69, Vol. II., is a handsome and as yet rather rare early-blooming Tulip. It is a native of Turkestan, whence it was sent by Russian collectors to the Botanical Gardens at St. Petersburg two or three years ago. Of all the known species of Tulip — and there are some twenty-six—this is perhaps the most showy and desirable as a garden plant. It blooms freely in April or May, its large goblet-shaped flowers being generally of a vivid orange-scarlet colour; but there are also purple and yellow-flowered forms of this Tulip. Herr Max Leichtlin, of Baden-Baden, by whom the plant was introduced into commerce, tells us that its bulbs are so extremely hardy that they will withstand freezing and thawing with impunity, and that even when the leaves are half grown they will endure a temperature as low as that of zero without any protection. The plant is a vigorous grower, attaining a height of from 9 in. to 15 in., and bearing flowers from 4 in. to 6 in. in diameter when fully expanded, and three or four lance-shaped, glaucous leaves with undulated margins, the whole of the upper surface being boldly blotched with purple or chocolate-brown. T. suaveolens again is a very early kind, bearing sweet-scented red and yellow blossoms well worth growing in a border of rich soil. Tulipa Gesneriana, which we now figure, is one of the finest of the species for border culture, whilst there are many other more or less beautiful. Now is a good time to plant, and, be it remembered, that when once well planted the species of Tulips need not be disturbed for years if the soil is warm and well drained. The bulbs of the garden Tulips are usually taken up and stored away in summer, but these, if left undisturbed in a warm sunny border, increase rapidly and produce plenty of fine flowers, but this cannot always be done therefore the best way is to have a reserve garden to which the Tulips can be removed when it is time to commence the summer planting. Here the bulbs will not only mature themselves, but throw off offsets which in two or three years make fine flowering bulbs. A good light and moist sandy soil is the kind of home best fitted for the Tulips during the summer. The blooming season is not near so short as is generally supposed, and between the earliest and the latest flowering kinds a considerable time intervenes. But beds of Tulips should be carpeted with small tufted or creeping plants, and there are many hardy flowering and foliage plants suited for the purpose. The White Rock Cress (Arabisalbida), together with its variegated form, the Aubrietias, Hepaticas, Primroses, Cowslip, the drooping Catchfly (Silene pendula), Pansies, early-flowering Violas, Saxifrages, the white Iberis (I. corifolia), Sedum acre aureum, the creeping Bugle (Ajuga reptans rubra) and many others make excellent carpets for beds of bulbs. When a collection of Tulips is sufficiently large to admit of its being done it is a good plan to rest the bulbs every third year by preventing them from blooming. They occupy but a small space in a reserve garden, and can be planted quite thickly. In order to grow Tulips to perfection, a light, rich, well-drained soil is required, but as their roots rarely extend more than 9 in. or 10 in. from the bulb, a position is easily made for them. They should be planted with from 3 in. to 4 in. of soil above the crown of the bulb; if planted nearer the surface and a severe winter follows, they have an odd way of burrowing to the required depth, and pro-

THE PARENT OF THE FLORISTS' TULIP (TULIPA GESNERIANA). ITALY.

ducing a fresh bulb there, to the injury of the flower. When the flowering is over, the flower-stem should be cut off, the leaves should be kept green and healthy until they wither naturally, when the bulbs may be lifted and laid in a dry, airy place out of sunshine for a fortnight or so, when the roots and leaves may be cleared away, offsets separated, and the bulbs stored in a dark dry place until October.

FRUIT.

NOTES ON PLANTING FRUIT TREES.

The best time to move deciduous trees is from the time they begin to lose their leaves until the sap begins to rise in spring. The lighter and drier the soil the earlier we should plant, in order that the trees by beginning to take root during the winter may more easily withstand the droughts of summer, to which they may be exposed. The stiffer and wetter the soil the later should we plant, in order to prevent the rotting of roots whose wounds are yet unhealed, an event probable in ground surcharged with moisture during winter.

The soil should have been trenched some time before beginning to plant, and just before planting, the surface of the soil, if poor, may have had a little manure added to it, but in general this is not necessary.

Fruit trees being rather delicate should be lifted with great care; they should never be torn up, and the roots, if resisting, cut off with the spade, as if they were superfluous organs. The preservation of the roots is of the greatest importance to the success of the operation. The greatest possible quantity of fibrous roots should be preserved uninjured.

The best time to plant is during mild, but not wet weather. Avoid planting during cold and drying winds, which destroy the fibrous roots, and also during frost, for the roots are far more sensible to cold than the stems. A few degrees below freezing point is sufficient to injure the roots of the greater number of fruit trees. Whenever we are obliged to plant in spring, it is well to take up the trees during winter and lay them down temporarily in a trench; the vegetation of the trees is thus retarded, and they will bear being planted out later.

Trees taken up in February and thus treated may be successfully planted out as late as the middle of May.

If the trees have to travel before being planted the greatest care should be taken to prevent the roots getting dry or being frozen on the way, and if the distance be great, the roots should be dipped into a rather liquid mixture of clay and cow manure, which, as it dries upon the roots, will preserve them from contact with the air, and afterwards the trees must be carefully packed, taking especial care of the roots.

The next operation is dressing the roots. Notwithstanding all the care that may have been taken, a certain quantity of the roots will either be found broken or dried by contact with the air. All these injured parts must be cut off with a sharp knife immediately above the damaged portion. The cut should be made underneath the limb, so as to let the section rest upon the soil. These wounds will heal, and the extremities will soon throw out a quantity of rootlets, replacing those that were destroyed. If we had not removed the injured parts the wounds would have become diseased and the roots unhealthy, and of no use to the tree. If we are forced to suppress a portion of the roots, then are we equally obliged to shorten the stem, in order to obtain an equilibrium between the respective extent of these two organs. As it is the extremities of the roots alone that are endowed with the faculty of absorption, and as many of these have been destroyed in transplanting, therefore must the tree develop new roots before it can recover; and as the leaves are the generating organs of the roots, it follows that a tree will recover if it develops shoots and leaves; but if a tree has lost about one-third of its roots in transplanting, and the stem remains its full length, then the small amount of sap supplied by the roots is insufficient to nourish the number of buds on the stem. These buds will expand in summer in little rosettes of puny leaves, incompetent to act in the formation of new roots. If the tree after a year's growth be taken up, the roots will be found in exactly the same condition as on the day in which it was planted; whereas if when planting the tree we suppress a portion of the stem equivalent to the loss the roots may have sustained, then the quantity of sap supplied by the roots remaining the same, but the number of buds being reduced, each of them will receive a larger supply, and will thus produce shoots and leaves fit to act in the formation of roots, and the tree recovers.

If the trees have been some days travelling and the roots are more or less dry, it is a good plan to plunge them for a day into water, to which may be added a little liquid manure. At all events it will be found advantageous after dressing the roots to dip them into a liquid mixture of clay and cowdung, completing this operation by dusting them over with wood-ashes. The development of rootlets is so stimulated by this coating, that plants thus treated gain nearly a year on the time necessary for their perfect recovery.

As to the depth at which to plant, the roots should be so placed that on the one hand they may receive the influence of the air, while on the other they should be guaranteed against drought. To fulfil these conditions the mean depth should be about 2 in., and the collar of the root should be so placed that when the soil sinks to its normal level this collar may be 2 in. below the surface of the soil. Our practice should, however, vary slightly, according to the nature of the soil. In a very light soil, and one consequently exposed to drought, the depth may be increased to 4 in., while in compact and damp soils the collar of the root should be on a level with the soil.

Trees grafted or budded low should have the junction of the graft with the stock at least 1 in. above the surface of the soil; without this precaution the graft might develop roots and the tree become a free stock. There are, moreover, certain trees, such as the Peach, when grafted on the Almond or free stock, and the Cherry grafted on Mahaleb, that must in all cases be planted with the collar of the root level with the surface of the soil. If planted deeper, the roots will frequently rot and the tree perish. It is better to plant too shallow than too deep; in the former case the roots will sink to a proper depth, whereas in the latter they rot.

In planting, a hole must be made in the ground sufficiently large to receive the roots of the trees without restraint. For standards it is sufficient to place the stem in a vertical position, but for wall trees the graft should be placed outwards, in order to shade the wounded part from the sun, as it thus heals much more quickly.

Wall trees should be so placed that the base of the stem may be about 16 in. from the wall, and the top of the tree slope towards and touch the wall. The roots should be spread with great care, and the hole filled up with fine earth or compost, so as to penetrate between the fibrous roots. The earth is then very lightly pressed; if dry it is better to water. Young trees raised in a nursery mutually protect each other from the heat of the sun and the action of drying winds. These, when planted out, are suddenly isolated and exposed to variations of temperature, and thus it sometimes happens that their tender bark hardens rapidly, loses its elasticity, refuses to expand with the swelling of the stem, and strangles the circulation of the sap. To prevent this accident, to diminish evaporation, and to protect the tree until rooted, a wash of lime, to which is added one-fourth in bulk of clay, may be brushed over the stem.

OMBU.

Free-bearing Pear.—If any readers of GARDENING should be thinking of planting Pear trees against a wall this autumn, and do not know what kind to plant, I would advise them to plant a tree or more of Glou Morceau. It is a sure bearer of fine large Pears; one fruit I had weighed 11 oz. this year, and many more near that weight; they keep well till Christmas. Trees that have been under my management for the last ten years have not failed to bear a fair crop every year. They are planted on a west wall in a gravelly soil ten miles west of London. —G. T.

Marie Louise d'Uccle Pear.—This is a dessert Pear of the highest merit. Here it is superior to, and ripens about ten days earlier than, the Marie Louise. Its flesh is fine-grained, buttery, and melting, very juicy, and richly-flavoured; the tree is quite hardy, a good bearer, and likes a rather heavy clay soil.—R. N., *Folkingham.*

Restricting Roots of Fig Trees.—Few fruit trees succeed for so long a period in a limited root area as the Fig, a fact to which the old, yet prolific, subjects that one often meets with in pots amply testify. In open air culture, on the other hand, barrenness is produced by over luxuriance and unripe wood; and therefore it becomes necessary to restrict the roots, so that short-jointed well-ripened wood may be secured. Under these conditions an annual crop of fruit may be counted on with more certainty than in the case of any fruit grown. We have here a south wall planted with Fig trees, the roots of which are effectually confined by the back wall—sunk 3 ft. deep—of a range of pits only 3 ft. distant from their stems. This narrow space is used as a foot-path, and the soil has thus become so hard that no other kind of fruit tree will grow at all satisfactorily. Yet the Figs succeed admirably, and ripen their fruit considerably earlier than those having unlimited root-room. When very heavy crops are swelling off on trees whose roots are thus restricted, a few thorough soakings of liquid manure will materially increase the size of the fruit.—J. G., *Suffolk.*

Preserving Flowers and Fruit.—Fruit and flowers may be preserved from decay and fading by immersing them in a solution of gum-arabic and water two or three times, waiting a sufficient time between each immersion to allow the gum to dry. This process covers the surfaces of the fruit with a thin coating of the gum, which is entirely impervious to the air, and thus prevents the decay of the fruit or the withering of the flower. Roses thus preserved have all the beauty of freshly-plucked ones, though they have been separated from the parent stem for many months. To insure success in experiments of this kind, it should be borne in mind that the whole surface must be completely covered; for if the air only gets entrance at a pin-hole, the labour will all be lost. In preserving specimens of fruit particular care should be taken to cover the stem, end and all, with the gum. A good way is to wind a thread of silk about the stem, and then sink it slowly in the solution, which should not be so strong as to leave a particle of the gum undissolved. The gum is so perfectly transparent that you can with difficulty detect its presence, except by the touch.

months, at 24s. P.O.O. payable to THOS. SPANSWICK, 37, Southampton Street, Strand.

TOWN GARDENING.

(Continued from page 414.)

Rockeries.—A rockery is easily constructed, and should find a place in every garden if there is a suitable position for it. London Pride, Creeping Jenny, and Stonecrop will grow almost anywhere, and some of the hardiest and most robust-growing Ferns may also be tried if the situation is at all favourable, but these are apt to get very scrubby and stunted in dusty and smoky corners. If you want good Ferns, and do not mind the expense, cover a corner over with glass, so as to form a miniature greenhouse or high frame. In such a place nearly all the hardy British Ferns will grow luxuriantly; they require but little air, and should have plenty of water when in growth. For such a glass case or Fernery the best are Athyrium Filix-fœmina (the Lady Fern), Polystichum angulare, and aculeatum, Polypodium vulgare and perhaps P. phegopteris and dryopteris, but these two last would require special soil and careful cultivation; in fact, all Ferns should have good fresh soil to grow in, as they have a great objection to spent or overworked material. The male Fern (Lastrea Filix-mas) is apt to grow too large for such a case, unless this is of a good size. It does well for a rockery out-of-doors. Lastrea dilatata, the Hart's-tongue (Scolopendrium), and the Ceterach officinarum do well; but the more delicate Ferns, such as the Hard Fern (Blechnum), and the Moonworts, Adder's-tongue, the Bladder Ferns, the Spleenworts (with the exception of Asplenium Adiantum nigrum and A. Ruta-muraria), require purer air than they can get in a town. The best soil for Ferns is a light, sandy, peaty loam, with plenty of fibre in it, such as the soil from a common, or it may be made artificially by mixing about equal parts of good loam, such as is used by florists, and peat, with a little leaf-mould and plenty of silver sand. The place where they grow should be well drained, so that plenty of water may be applied to them when in growth.

Flowering Plants.—Returning to flowering plants, we think that the bedding-out system is overdone in the present day. It is very expensive, and the beds are only in beauty for a little more than three months, or four at the outside. If done at all it must be done well, only well-grown and hardened plants of suitable kinds be employed, and all of each variety must be nearly identical in height, shape, habit, &c. So we advise, do not have your garden all straight lines and regular curves of exactly similar plants, but though these are very well, and indeed desirable to a moderate extent, vary their mathematical precision by a mixed border or two and a few beds for specially favourite flowers; for bear in mind that plants never do so well as when they have a specially prepared bed all to themselves. This should be, of course, made in the most suitable position as to sun, shade, &c., that can be had, and if the bed is formed and filled with just the kind of soil in which the plants most delight, far better results will be given than where a number of different families are mixed together, and the soil, &c., has to be the best mean or average that you can strike amongst the requirements of all.

Designs for Flower Beds.—Regarding designs for flower beds, any one possessing a fairly correct eye and average amount of taste can design and cut out suitable shapes. We always merely measure and peg out the principal points, corners, &c., of the beds on the turf, take a sharp spade and cut the design out straight away without any bother of plans or patterns, and no assistance but a line for straight edges, perhaps. Diamonds, circles, ovals, crescents, and such simple shapes we consider far more suitable, especially where room is limited, than more intricate designs, though such as well proportioned stars, Greek crosses, &c., are very effective under certain circumstances.

Contrasting Colours.—As to contrasting the different colours in the beds, let every one follow his taste, as what pleases one is sometimes almost offensive to the eye of another; almost any reasonable combination, always aiming at obtaining as effective a contrast of one colour with another, will look well if well carried out. This is the one great secret of successful carpet bedding. The beds must have been well cut out, *i.e.*, no crooked lines or irregular curves allowed, and in the planting all the "stuff" must be, as remarked above, as even as possible, and have all lines, &c., as carefully drawn and filled in as you can; in fact, all in this respect should be perfect. In Nature colours harmonise far better than they do in art; as, for instance, yellow Calceolarias look very well against scarlet Geraniums in a border, and yet yellow and red contrasted in a picture are anything but pleasing. Of course two different shades of any colour must not be put together, unless where a regular gradation is employed, as crimson, scarlet, pink, blush, and white, in Geraniums or other plants, which sometimes look very well. Blue and red, and especially blue and purple or red and purple, are shocking. Some of the best contrasts we know are—red next white, such as a ring of scarlet Geraniums round a large plant of Cineraria maritima, or Centaurea candidissima, or *vice versâ*; blue and white, such as Lobelia next a row of white Verbenas or Petunias, or blue and white Verbenas contiguous; Amarantus mel. ruber looks well next a white-leaved Centaurea or Cineraria, and one of the prettiest is a row of white-leaved Geranium, as Flower of Spring, next a row of dark purple Pansy, only neither of these, the Pansy especially, do well in towns. Except in the case of carpet bedding proper, the plants should be arranged according to height, so as to slope from the centre downwards towards the sides. Something tall for the centre, a Canna or two, a group of striped Maize, or an old and large plant of Cineraria maritima, does well; then the others should be graduated in height as well as contrasted in colour. It is a great pity that the variegated-leaved Geraniums do not succeed in towns, they are so useful. But there are plenty of other things. One good design is, a purple-leaved Canna in the centre, then a ring of Cineraria maritima or candidissima, then scarlet Geraniums, then a ring of Calceolarias (yellow), and an edge of Lobelia, or if there is room get something else in between the last two, preferably white; or a large plant of Cineraria candidissima, or a clump of striped Maize for the centre, outside that scarlet Geraniums, then white Petunias, or white Phlox Drummondi, and an edge of Lobelia, or if the bed is large have a ring of Amarantus mel. ruber outside the white, and then Golden Feather for the edge.

It is of no use attempting to get such things as Coleus, Alternantheras, Iresines, &c., to grow in the smoky air of a town, though Ageratums may be made to do fairly well. And what is known as "spring bedding," lovely as it is, must not be tried either, or if it is, failure is sure to result; in short, all such things as Pansies, Violas, Alyssum, Myosotis (Forget-me not), &c., will not do any good, and it is no use attempting them.

In fine, plant your garden as thickly as you can, for some of the things are sure to fail in some way; if one thing does not succeed, try another. Plant plenty of Vines, Virginian Creeper, Ivy, and Jasmine to cover all bare walls, and put a plant of some sort in wherever it is likely to do well.

Soil.

This if often found to be very unsuitable for the healthy growth of plants. Either it is, from long neglect, want of manure, over-draining, &c., wretchedly poor, dusty and dry, and often consists more of rubbish, broken tiles, and slates, and such-like, than of anything worth the name of soil; or in damp and low localities it is often the very opposite of this—heavy, black, sticky, sodden, and utterly unwholesome. This last is far worse than the first, and can hardly be brought into a wholesome state by any means; perhaps the best way would be to burn it all if it cannot be altogether removed. In laying out a garden in town where either of these conditions are approached, or indeed in any case, by far the best thing to do is, after having settled on the plan to be carried out, to remove all the soil from the beds to a depth of 2 ft. or or 3 ft., have it taken right away, and after having made the bottom smooth and hard, put 6 in. or 8 in. of broken bricks, ballast, or good rubble of any kind for drainage; on that a layer of turf sods turned upside down, and then fill up the beds with good fresh soil from the country, varying slightly in its nature according to the class of plants desired to be grown. Good mellow fibrous loam, enriched with a moderate quantity of well-rotted manure of some kind, and if at all stiff, lightened with silver or river sand, is about the best stuff for general purposes, but the most suitable soil for each class of plant will be given in the articles on each farther on.

Turfy loam, suitable for this purpose, can be purchased in London for about 10s. per cart-load. But where this cannot be done (and it is certainly expensive), and if the soil is not utterly useless, a great deal may be done to improve it. Where it is too light and rubbishy, the beds should be dug out nearly 3 ft. deep, and at that depth a stratum of heavier, moister mould is often to be met with. If so, set it by itself, reserving only a little of the best of it to be brought to the top, as having been shut out from the action of the sun and air for so long, it is not at all in a suitable state for plants to grow in, however good it may be in itself; then if drainage is deficient, put 6 in. or 8 in. of rubble in the bottom, and over that the turf sods, as before mentioned, that is, if they can be had; if not, littery manure will do. Above that put the heavier portion of the soil, mixed with manure, and for the top 12 in. or 15 in.; use the ordinary soil of the garden, roughly sifted, all rubbish removed, and mixed with plenty of rotten manure, and, if possible, a good proportion of good fresh maiden loam on the top, or worked in near the surface. Leaf-mould (thoroughly decayed leaves) is very useful, and for most flowers is preferable to a quantity of manure, especially if this is not very old and rotten. Beds made as described will last for many years, and afford the best possible chance of success to such plants as Geraniums, Fuchsias, Petunias, &c., as well as to all kinds of annuals, though there are some plants, as Primroses, Violets, Pansies, and Hollyhocks, that prefer a closer and more retentive soil than such a plan as this would give. If it were desired to grow such as these, it would be advisable, unless the ground were naturally insufficiently drained, to leave out the drainage, and merely "trench" and manure the soil to a good depth.

Manure.—Where one has a garden in town there is no excuse for practising economy in the matter of manure on the ground of its expense. In London good stable manure can be had (fresh) for about 1s. per cartload, and can, indeed, often be obtained merely by bringing it away. Spent or used Hops can also be had for nothing, or next to nothing, at most breweries in town, and nothing can be better in the garden than these; their uses are almost countless. When fresh, they make of themselves, and with but little turning to sweeten, a gentle and useful hotbed. In this they are much superior to stable manure; every gardener knows what a nuisance the labour and delay of the frequent turnings necessary to bring manure into a sweet and useful condition is, whereas Hops require little or none of this trouble, but may be put together almost immediately, and are, in addition, never so rank and dangerous as the other. When rotted they are equal, and for some things, such as vegetables, superior to manure, when dug into the ground. When a few months old, and the fermentation is well over, a handful put over the drainage is the best possible thing in potting nearly all kinds of plants, excepting, of course, all hard-wooded subjects, for which only clean Moss should be used. When pretty well rotted, too, Hops may be used with great success for filling boxes in which to prick out Pyrethrum (Golden Feather) and other similar plants. Little or no soil is needed, except just a surfacing for small things, as Lobelias, and it is astonishing what a free, rapid, and healthy growth such plants make in this material. We always use it largely in the shallow boxes used for pricking out nearly all seedling plants, only putting 1 in. or so of soil on the top. For plunging pots in frames, greenhouses, or out-of-doors, either when it is in a heating state or afterwards, nothing surpasses it, and when very old and decayed, it is good as part of the compost for large pots or boxes, where lightness of staple is required

Tan can also be almost always easily and cheaply obtained in London and most large towns, and after a long experience we have found that nothing makes such a good, lasting, and useful hotbed for raising seeds, striking cuttings, &c., as fresh tan mixed with a smaller or greater proportion of stable manure. In the early spring, when a good heat is wanted, use about equal parts of the tan and manure, either mixed or in layers, preferring the former, and covering with 6 in. or 8 in. of fresh clean tan; it is so clean, and sweet, and pleasant to plunge the pots in, and no earth is needed. As the weather gets warmer less and less manure is needed, and in summer only a very small proportion, or none at all, is required. The superiority of tan over all other heating material is, that it is drier and more open in character, and never gets into that nasty sodden and caked condition stable manure is apt to do. It does not give off nearly so much steam as manure, thereby giving a drier atmosphere inside the frame; and especially for early work any gardener knows what an advantage that is, remembering his sad experiences of costly and carefully-reared seedlings all damped off in a single night from too much steam. What little steam there is from tan is not rank, but sweet almost from the first, so that plants or seed-pans may be placed in the frame far sooner than when manure is used. This leads us to remark that town gardeners have a by-no-means-to-be-despised advantage, viz., that the air being so much drier than in the country, damping off is not nearly such a serious difficulty. When living in the heart of London we hardly knew what damping meant. Frames were shut up close every night during the spring and no harm ensued, but on removing to the country again it took a long time to get accustomed to the altered circumstances, and many a fine pot or pan of seedlings were lost.

Potting Soil.—The various kinds of soil should be kept in bins, if possible, or in heaps, and they must be well covered with some waterproof material, and should stand on a dry bottom, impervious to worms; this keeps the soil dry in wet weather and moist in dry weather. A nice supply of nice fibrous yellow loam is of great importance, and a heap of a commoner description for ordinary purposes, well decayed leaf-mould, ditto manure, peat, and silver sand should all have a place. All should be kept separate, at least where a variety of plants is grown, as nearly everything needs a slightly different compost in which to do its best. It is well, however, to have a good heap of ordinary potting mould ready mixed. This should consist of about two-thirds good sound turfy loam and the other third of well decayed manure, with a little leaf-mould and silver sand, enough to insure porosity. If the loam is sandy, use less sand; if stiff, use more; and if it is poor, add a little more manure. This soil will be suitable for Geraniums, Fuchsias, Calceolarias, and most ordinary pot plants. For young struck plants or seedlings, when putting them into small pots use (as a rule) about two parts leaf-mould, one of loam, one or two parts of sand, and no manure. This will do for young Fuchsias, Verbenas, Primulas, Cinerarias, and Balsams; also, with more sand, for striking cuttings of all soft-wooded plants. For sowing seeds, especially fine ones, as Lobelias, Primulas, Petunias, &c., use fine leaf-mould and sand in equal parts, the finest on the top.

Potting.—Where much potting, &c., has to be done, all should be performed systematically and orderly, or a great waste of time and money will result. Unless where there is absolutely no other place in which to do it, potting should never be done in a greenhouse, neither should any heaps of soil or anything of the kind be kept there. In a greenhouse cleanliness should reign paramount; no empty, or at least dirty, pots or empty boxes should be seen. Wherever practicable, a proper potting shed should be erected, with bins for soil and manures, sand, &c.; such a place is extremely useful in many ways, especially if it can be warmed in winter a little in some way; it can then be used for storing the dry roots of Dahlias, Fuchsias, and other things, and the soil kept in such a place is always warm enough for use. Where the luxury of a potting shed cannot be had, have a bench fixed in some convenient corner of the yard or other suitable place, under cover if possible, as a sudden shower often brings a batch of potting to an untimely end.

(To be continued.)

House and Window Gardening.

Growing Bulbs in Boxes.—One of the best methods of growing Hyacinths, Snowdrops, and Polyanthus Narcissus for room decoration in the spring is to plant the bulbs at once in boxes of light, rich, loamy soil, after which they should be placed in a shady corner, and covered to a depth of from 4 in. to 6 in. with common yellow sand or coal ashes. The object of this is to keep the bulbs moist and firmly in their places until they have rooted freely into the soil, and also to protect them from any sudden changes of temperature. It is usual for amateurs to neglect this part of bulb culture entirely, and this accounts in a great measure for their non-success in bulb growing. The bulbs are bought and potted or planted in boxes, and subjected to the temperature of a warm room, a proceeding which at once causes the growth to be weak and colourless, the usual result being either puny few-flowered spikes, or no flowers at all, a state of things which is commonly accounted for by accusing the seedsman of having sold bad bulbs. After planting the bulbs, however, in the boxes, and banking them up out-of-doors with sand or ashes, then the question arises—How long they are to remain thus before they are brought into the room or window? But this is a matter of no very great importance—they may remain at least a month or six weeks, after which it will be found that the plump yellowish-green buds have pushed into the sand, a tolerably sure sign that the roots are at work in the soil below. If more than one box is filled with bulbs one can remain a month under the sand, after which the latter should be cleared off, taking care not to injure the bulb growths in the operation, and having levelled the soil about the bulbs, wash the box and place it near or in the window. The other boxes may be removed at intervals of a week or a fortnight, so as to have the flowers in gradual succession, and in this manner the room or window garden can be kept gay for two or three months in the spring. As to planting the bulbs, it is a general rule to plant Snowdrops about 2 in. deep in the soil; the same applies to Crocuses, while little more than two-thirds of the bulbs of Hyacinths and Narcissi are buried in the soil, that is when they are grown in pots or boxes. When planted in the open beds or borders, however, they are buried just like all other bulbous plants. Our illustration represents a box of spring flowering bulbs, and it is difficult to imagine a more pleasing room or window ornament during the early spring months. Of course all the bulbs named are quite hardy, and while some of the more ornamental boxes are brought inside, others—ordinary window boxes—may be placed on the sill outside, where the bulbs will bloom nearly as well as those indoors, but a little later.

Box of Spring Bulbs.

ROSES.

Planting Roses.—Those who wish to make plantations of Roses should at once set to work and make the best of the fine weather. Those who have not selected their plants should at once do so, for by planting early and giving them a fair chance of rooting, a good supply of Roses will be ensured the following season. Well-rooted, strong plants should be selected, and it is well to remember that Roses on their own roots, or on the Brier, are superior to those on any other stock. They do well on the Manetti, but their suckers often prove troublesome, and when the plants grow strongly the buds are liable to be pushed off. Where Roses are required for planting upon lawns in the form of umbrella trees, pyramids, or bushes, strong plants of the most vigorous-growing varieties should be selected, such as Baronne Prévost and Jules Margottin; the ground should be specially prepared for standards. Planted in this way, the subsoil should be taken out of a circle 5 ft. in diameter, and filled in with good drainage and plenty of good loam and rotten cow manure. Plant and tread all firm, and in placing the turf allow enough soil to admit of the turf settling down to its original level in the spring. In clearing out Rose plantations and digging borders, the long autumn-straggling shoots should be shortened back, so as to give the plants a neat appearance until the spring pruning time has arrived. Trellis or pole Roses should be slightly pruned back and tied in with the same object. Cuttings may still be made and inserted out-of-doors if required. Rose beds should be dug over and manured, great care being taken in digging between the plants not to break their fibrous roots. Carefully root out all suckers as the digging proceeds, as it saves much trouble the following season if they are now removed with a sharp knife.

Manuring Roses.—Although quite opposed to the theory enunciated in GARDENING on this subject by "D. T. F.," I am very glad it has been broached, because I consider it requires ventilation. "D. T. F." commences with a dictum with which I acquiesce—viz., Rose trees (?) want feeding;" and I also agree with him in his remark that "there is a proper time for manuring Roses," and also that they require food in a state fit for their immediate consumption, and that it shall be given at a time when the plant is capable of consuming it. But I maintain that it is useless giving a stimulant to Rose trees, or any other plant or tree, unless the roots are in a fit state to absorb it, and I also maintain that Rose trees cannot receive any benefit whatever from manure applied to them after they have, to use a homely expression, "gone to sleep." I join issue with "D. T. F." in his statement that "the roots of Rose trees are abnormally active during the winter," and I ask him to give his reason for that assertion, and to give me any other example of a plant that absorbs food given to it whilst in a dormant state. Let him dig up a Rose tree, or any other plant, in summer, and again in winter, and observe the white rootlets in the former and their absence in the latter season, and then say they are as capable of absorbing nourishment at one time as at the other. I maintain that when a plant is dormant it cannot take nourishment of any kind—the same with an animal or human being. When a plant is growing food must be given at a time congenial to their nature, and in a state fit for their consumption. Liquid manure is the food *par excellence* for Rose trees, and the bloom of a Rose tree depends very much upon the treatment the tree receives immediately after it has bloomed previously, as in the case of numberless other plants, and saturation with sewage in March or April will not be as beneficial in obtaining good blossoms as if applied in the previous July and August. To have Roses you must have strong wood, and if it is not there in March it cannot be there in June. The only way to attain this end is by liberal treatment when the tree is in a growing condition, and can absorb nourishing food. Saturating Roses in March and April, before the bloom buds show, with sewage or strong manure, would have a tendency to produce wood and leaves instead of blooms, but if given after the bloom buds show, it might assist the tree to carry a greater number of flowers, but nothing more.—CALCARIA.

Roses in Pots.—These should now be placed under glass, or in some open sheds (if glazed all the better), and if the protection of a shed cannot be afforded them the Hybrid Perpetuals should be plunged in some old tan or Cocoa-nut fibre, or in ashes, so as to protect their roots from frost. Tea varieties can be stowed away in cold pits or frames that are not in use, or, better still, in cold houses. In removing Roses to their winter quarters, select some of the best of the late-flowering kinds and place them in a cool, airy house. Water them sparingly ; remove all buds and leaves that are damping off ; dust with sulphur should mildew show itself ; and by careful treatment in this way a supply of cut flowers may be had up to Christmas. I have found good plants of such sorts as Gloire de Dijon, Madame Falcot, Madame de St. Joseph, Safrano, Goubault, Rubens, and Souvenir de la Malmaison invaluable for flowering in autumn and winter. These, under ordinary treatment, produce plenty of wood as well as flowers. Maréchal Niel should occupy a house in which there is some artificial heat in winter to encourage growth and induce the buds to expand. I have always been successful in forcing this variety, which I start in November, subjecting it to about the same treatment as that usually given to an early Vinery till the buds show themselves, after which syringing must be discontinued, as water is apt to blacken and spoil the flowers. Under skilful treatment, Maréchal Niel will produce plenty of fine flowers at Christmas and all through the months of January and February. I would recommend every one to grow a few standard Roses for winter work, and where they cannot be got from a nursery, this is a good time to lift such plants from the open ground and pot them.—H. G.

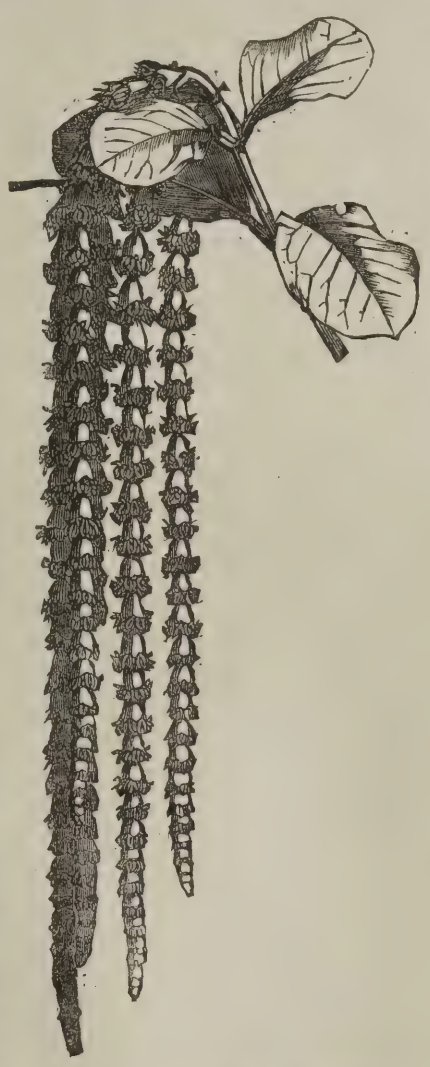
Belle Lyonnaise Tea-scented Rose.—This nearly equals Maréchal Niel in usefulness. It has the habit of Gloire de Dijon, but is very superior to it in colour, being a deep canary-yellow. It is, in short, a first-class Rose for indoor culture. The characteristic of this Rose is, it always seems to bloom late, while Maréchal Niel prefers showing its beauty in spring. As an autumn-blooming creeper it may be strongly recommended.—C.

THE SHRUBBERY.

Berberis Hedges. — Berberis asiatica thrives well in isolated positions, and also as a background shrub, as it grows rapidly and fruits most freely where exposed. As a hedge plant it is unequalled for rapidity of growth and general appearance. We have hedges of it here many years old, carefully shorn, and varying from 2 ft. to 6 ft. in height, according to circumstances, as in many cases it forms fences to the gardens of our cottagers ; such hedges should be shorn twice a year, viz., at the end of June or early in July, and again at the end of February. By the summer shearing the plant is made almost an evergreen, as the autumnal growth retains its leaves much longer than it otherwise would do ; as a field hedge, the winter shearing would be sufficient. Should the hedge be neglected for a few years, it naturally grows upwards, and gets naked at the bottom, a fault that may be readily and completely remedied in one season by cutting it down to the required height. Young stock of this Berberis is easily raised from seed. —J. G., *Exeter*.

Hardiness of Fever Gum Trees.—I have frequently seen questions in GARDENING regarding the hardiness of Eucalyptus globulus. Last February I obtained from a nursery two seedlings a few inches high, and at once planted them out in the open border. This was cruel treatment, especially in a Scotch climate and during such bitter weather. Both plants were sorely pinched by the severe cold and biting east winds, but survived, and have during these eight months grown into two handsome young trees 6 ft. high, their beautiful glaucous foliage standing out most distinctly from all else in the herbaceous border. From both having stood such a severe test last winter when so young and tender, and when they were transplanted from the hothouse without hardening, I have a good hope they may prove quite hardy, more especially as the lower part of the stems have acquired a tree-like bark. I am not aware of such a severe test having been made, and so send you this for what it may be worth.—W. T. B.

A Winter-flowering Wall Plant.—Garrya elliptica is one of the most attractive of all ornamental-flowering evergreen shrubs. It grows from 6 ft. to 10 ft. high, and has a rather dense and spreading head, furnished with numerous slender shoots, which are downy when young, but quite smooth when fully matured. It is a native of North-west America and California. It is easily increased either by layers or by means of cuttings of the half-ripened shoots, and grows freely in any good garden soil. The leaves are somewhat oblong, with a small acute point, thick and leathery in texture. The flowers are arranged in pendulous catkin-like racemes, as shown in the accompanying illustration, and are produced from December to March. It may be grown either on a wall or as a bush. Its long greenish-yellow pendulous catkins are useful in winter decorations.



Winter-blooming Shrub (Garrya elliptica).

Improving Clay Soils.—I have been reading GARDENING ILLUSTRATED for Oct. 16. I see it recommended by F. Nash to burn clay and mix with the soil with a view to improve it. My experience is that this is the best thing to do with it. I have had 15 years in a clay garden, so I think I can speak with some authority, for I believe ours is the worst specimen of clay ground I ever saw ; but I cannot agree with F. Nash as to the way to do it or the man he is going to employ. I may say our place is in the immediate vicinity of several brickfields, and I feel sure a man may burn bricks all his life and still be ignorant of burning soil, neither could he burn it in the way he suggests, viz., with chips. He may burn a small quantity, but to make a good job of it, it requires small coal. We use what we call the Forest Slack ; it costs about 7s. per ton. Now the way we do it, and experience tells me it is the best way, is as follows : Supposing we have a heap of clay, say from foundations or elsewhere, we get a barrowful of chumps of wood and place them carefully in a heap and set fire to them ; as soon as the chumps are lit we cover them over with not more than 6 in. of clay, taking car «to put it on as lightly as possible ; as soon as the fire has burned through, on no account before, we give the heap a slight sprinkling of small coal, then add another 6 in. of clay. In the morning if the whole mass is burned through we rake back the unburned from the bottom of the heap, and with a tool we have for the purpose we draw the fire out wider, and immediately the fire is drawn give a sprinkling of coal ; then throw in what was raked back with more clay from the heap. Great care is required not to put too much on at a time until you have three or four cartloads; then you can put on more clay, but be sure and draw the fire every morning, else there will be clinkers in the middle of the heap. It is a good plan to knead the clay if it has been exposed to the weather.—J. ROGERS.

GLASSHOUSES & FRAMES.

CHRISTMAS FLOWERING GREENHOUSE CLIMBERS.

IN a greenhouse light and warm, say from 45° to 50°, I find no difficulty in having climbing plants to flower in it at Christmas ; but if the roof were densely covered with creepers, it would interfere with whatever is growing underneath, and in that way I should lose as much as I gain. However, there are many plants that may be trained thinly on the roof and yet give plants growing beneath a fair amount of light, and first and foremost may be mentioned Tropæolums of the small-leaved Lobbianum section, young plants of which turned out in spring and trained thinly over the roof during summer will hang about and keep the house aglow with bright flowers throughout the winter. A few of the faster-growing Tea Roses might be planted along the front, and afterwards led here and there up the rafters. Habrothamnus elegans and fascicularis are capital plants for walls, pillars, or for training up the rafters.

Some Fuchsias, again, when pruned back early in August, if planted out in a good border, flower splendidly in winter. Dominiana, Carolina, Venus de Medici, and an old double variety called grandiflora plena I have had do splendidly when treated thus. I have also had some of the stronger-growing scarlet Geraniums, such as the old Giant and others, planted out in a well-drained border and trained up to the roof, flower better in winter than summer, because the trusses lasted so much longer. It is astonishing what a time a truss of scarlet Geranium will keep in good condition in a light, well-ventilated house, and, of course, in winter there must be a fair amount of artificial heat to admit of the necessary ventilation if the flowers are to be kept in good condition. Heliotropes may be shortened back and treated the same as Fuchsias for winter flowering.

Luculia gratissima, if trained against the end or the back wall, will fill the house with its delicious fragrance in the months of December and January. Begonia fuchsioides looks exceedingly bright and pretty in the front of a warm greenhouse, trained up to the roof with a single stem, and then allowed to extend itself. Several of the Veronicas of the Andersoni section in the same way, trained up the rafters, have a pretty effect.

Tacsonia mollissima and T. Van Volxemi are exceedingly handsome fast-growing creepers, and very rarely out of bloom. By training the main stem to the rafters or girders of a conservatory, and allowing the young shoots to depend thinly from them, they show off their beautiful flowers to great advantage. We have just now a plant of mollissima, growing in the manner described above, that has been flowering continuously all the summer, and, from the number of buds it is now showing, it promises to be almost equally good during the greater part of the coming winter. This variety has trumpet-shaped flowers, the tube of which is about 4 in. long and of a delicate pale green

colour, which shows off the beautiful pink petals to great advantage. T. Van Volxemi is a strikingly beautiful variety. It has large crimson flowers that are borne on thread-like stems, which vary from 12 in. to 18 in. in length, and, as these occur at almost every joint, some idea of the effect produced by such a number of flowers depending in this way may readily be formed. Although not so vigorous as mollissima, it is sufficiently so for ordinary purposes, and will cover as much space in a season as can generally be devoted to one variety. Tacsonia exoniensis is a hybrid between the varieties above named. The flowers are of a deep rose-pink colour with violet throat, and it possesses the good qualities of both parents. Unfortunately, most of the Tacsonias are rather subject to scale, which, if not looked after and kept in check, increase to a great extent, and soon throw the plants out of health, but as these pests are mainly on the stems, they may be destroyed by using a stiff brush and some of the insect-destroying compounds. With a little care and management a greenhouse roof may be made to assume a very gay appearance in winter without materially injuring plants beneath the climbers. Of course, with plants in flower the watering-pot must be used cautiously, so as to keep the atmosphere of the house nearly dry. H. J. S.

Winter Tree Carnations.—In a collection of a dozen sorts of these useful plants we find Zouave, Covent Garden Scarlet, Valiant, and Miss Jolliffe to be the freest flowerers in winter. The colours of the three first consist of different shades of scarlet. The last is a beautiful pale pink variety, and most deliciously scented. Good bushy plants of these in 5-in. and 6-in. pots are now supplying us with fine blooms. They are growing in a light airy house in a night temperature of 50°. We propagate a stock annually, dividing it into two sections. The first is introduced into heat early in March ; the second late in April. The cuttings are taken from plants in a growing state, and about a dozen are dibbled into a 5-in. pot in a compost of two parts sandy loam and one part each of well-rotted leaf soil and silver sand, surfacing the pots with half-an-inch of sand. We then plunge them in bottom heat in a close frame or pit, keeping them shaded during sunshine, and damping them over daily with a fine syringe. As soon as they are rooted we pot them off into 3-in. pots in the same compost as has just been mentioned, replacing them in the pit until they have become established ; they are then gradually hardened off in a cold pit as soon as the bedding plants are removed from some turf pits which we have. When the Carnations are potted into their blooming pots we use a compost of two parts friable loam to one part leaf-mould and pigeon manure in about equal quantities. A small Hazel stick, about 2 ft. long, is put to each plant, to which they are tied as they grow. They are then set on a bed of ashes in the turf pit ; this is done, say, the first week in June. The treatment from that time until they are housed in September consists merely in seeing that they do not suffer from want of water. They should be protected from heavy rains with some old sashes, but they should be gently syringed in the evenings of hot sunny days. By following the above treatment we have not been without Carnation blooms for a week during the past three years, and the prolongation of the fragrant bloom of these Carnations through the winter and spring months constitutes one of the most gratifying successes of our indoor gardening.—C. J.

Winter Propagation of Flowering Plants.—Many plants are better propagated in winter than at any other time. For years past I have planted all my Pansy cuttings in November. Hardy Fuchsias, Carnations, and Picotees will all, or nearly all, root if treated thus. I have also seen a house full of Tea Roses, all of which were raised in the same way, scarcely one having failed. Calceolarias, of course, should be always so treated, the advantage of this system being that you have merely to prick them out thickly in a frame, and leave them alone until spring, no attention whatever being required in an ordinary way. Hand-glasses also serve the purpose very well. Nothing, of course, that is really tender will endure this treatment, but it is astonishing what an immense number of plants may be successfully raised thus. The frame should be kept close until spring, and there is no necessity for sheltering with nets.—D. A. W.

Coprosma Baueriana variegata.—This is one of the prettiest of subjects for greenhouse decoration during the winter months. The variegation is very clear and constant, the culture very easy, although to obtain a really good specimen some little pains must be taken in the earlier stages of growth. This plant naturally assumes a somewhat dwarf spreading habit, thus fitting it for basket culture. A good, well-furnished specimen proves a very effective ornament to the conservatory. When grown in pots, the most important point in its culture is to obtain a well-furnished base by means of frequently stopping the points of the young shoots. A few sticks being inserted around the edge of the pot, the shrubs may be trained to them in such a manner as to form a compact, well-furnished specimen. This plant is very effective by gaslight, and should be grown by those requiring plants for such a purpose.—J. C., *Byfleet.*

Erica persoluta alba.—This is a very useful Heath either for general decoration or for cutting from. Little sprays mounted on wire are of great service in bouquet making. It is of easy culture, and may be grown to perfection by anyone having the convenience of a cold frame. This is about the only species of Heath which will bear forcing. Placed in gentle warmth in November, it comes into bloom by the beginning of the year, the warmth having the effect of increasing the purity of the flowers.—J. C.

Spring Flowers.—Both Russian and Neapolitan Violets are especially suitable for frame culture ; plants that have been prepared in the usual way by being planted out should now be placed in 6-in. pots in ordinary loam, and the soil made tolerably firm. Hyacinths of different colours should be potted and treated as has been advised for greenhouse use. With these may be included Scilla biflora, S. hyacinthoides, and S. sibirica, charming little plants that will flower beautifully in pots. Some Lily of the Valley should also be prepared. It will come in several weeks earlier than in the open ground. The imported roots, as now sold in selected crowns, are the best ; or if the amateur happens to have plenty of this fragrant favourite growing, he may take some up forthwith, choosing the blooming crowns. These may be readily distinguished, by their thick plump buds, from the weaker ones, which should at once be replanted in an open situation in rich soil, to grow stronger for another season. A 6-in. pot will hold a dozen of these flowering crowns. A dry, sheltered, sunny situation should be selected, and the warmer it is the earlier will the plants flower, as every additional ray of sun in the spring is a gain to them when managed in this way. For this reason let the frame slope considerably to the south, and to effect this, raise the ground at the back. On this place 8 in. or 10 in. of ashes, on which to stand the pots. Thus elevated on the dry material, the superfluous moisture from watering will drain off. Do not by any means lower the ground, for the loss that ensues through the inevitable accumulation of damp is much greater than the gain. Pack round the side and ends of the frame 18 in. of dry leaves, laying them up level with the top all round ; on this place boards, made to overlap each other at the corners, and then nailed ; let them fit with their inner edges close to the frame on all sides, and slope outwards a little, so as to throw off the wet. The lining of leaves, kept dry, will ward off a good deal of frost. As this lining settles during the winter, have in readiness more leaves to replenish it, and round the sides put 1 in. or 2 in. of litter, to prevent their being blown about, and drive down a few stakes, at intervals of 12 in. or 15 in., to keep all in its place. Give more or less air, according to the temperature, on all days when it does not freeze. Use no more water than is necessary to keep the earth in the pots in a sufficiently moist condition, which may be best described as being between wet and dry, or so that it will not soil the fingers much when compressed in the hand. When there is an appearance of frost in the evenings put mats over the glass, and secure them from the action of the wind by weighting them with pieces of board. Later on in the winter place 1 ft. of litter on the glass over the mats, and a wooden shutter over all. This will keep the litter dry, and hold it in its place. From a large frame or frames filled with plants of this description, and managed in this way, amateurs may enjoy, through the early spring, a quantity of beautiful flowers; whereas, if they attempt to winter Pelargoniums, or similar tender greenhouse subjects that suffer through damp, they are almost certain of disappointment.—B. T.

Kalosanthes coccinea.—There are few more showy, and at the same time more sweetly fragrant, plants than this. To grow and flower it well was at one time considered a creditable feat, though its culture is not a difficult matter. It is one of our oldest and finest greenhouse plants, and sometimes it is planted out during the summer in the flower garden. Cuttings of its succulent shoots struck now, potted off the following spring, and allowed to grow all the summer in any light, airy structure, or in a warm exposure out-of-doors, flower the same year. Like most of its class, it strikes freely, and the young plants may be potted singly in 6-in. pots in a compost of loam and sand chiefly, mixed with a proportion of broken potsherds and charcoal. The shoots are better not pinched ; but if tops be chosen for cuttings which are just breaking into a number of shoots, as they often do, pinching will not be necessary. The great point as regards the summer culture of plants of Kalosanthes is to get their growth well ripened, and with this object, in the south at least, and even in the north, it is a good plan to plunge them in a warm border in front of a hothouse, where they will get all the sun and heat possible ; in such a situation they do almost better than under glass. Water should be regularly, but sparingly supplied, and towards August they should be kept rather dry, to induce the formation of flower-buds, when they may be introduced to the conservatory and placed in a good light. The Kalosanthes is from the dry slopes of the Cape of Good Hope, and, as might be expected, the successful flowering of it depends very much on exposure to the sun and air, together with a limited supply of moisture. In order to increase the heat about the roots, I have seen the plants plunged in a bed of sand formed close to the front wall of a plant stove, where between the heat that struck outwards from the pipes inside the house and the sun together, they were subjected to a temperature that would have been destruction to many other subjects, but which suited them admirably.—S.

Arrangement of Cottage Gardens.—In the arrangement or laying out of cottage gardens several advantages will be obtained by growing the fruits and vegetables separately, that is, not intermixed, as at present. In the first place there would be a saving of labour, as the groups or patches of fruit trees would not require the same amount of manuring or digging as should be given to annual crops of vegetables only. If the ground occupied by fruit trees had been thoroughly trenched and prepared before they were planted, after the first half-dozen years little beyond surface culture and cleanliness would be required. Another advantage possessed by this system of grouping would be the shelter it would give, for by planting the Apples on the windward side, and afterwards the Pears, Plums, and Cherries in rotation, the hardier trees would shelter the tender kinds, and fruit trees in spring often suffer as much from cold, cutting winds as from actual frost. I believe the subject—separating the fruits from the vegetables—fully merits the serious consideration of all who contemplate making new gardens or renovating old ones. I should have no objection to low espaliers of Gooseberries or Currants, as they might be planted close to the walk and be utilised for edgings instead of Box or anything else equally unprofitable. It may be thought that there is a saving of space by growing fruits round vegetable quarters, but this is a mistake, and both the fruits and vegetables suffer by being intermixed ; and this will be more apparent where the soil and climate are unfavourable, though of course espaliers are less objectionable than any other form, as they occupy less space and consequently shade less. Wherever the garden is irregular in shape—which many cottage gardens are—the fruit trees might be so arranged as to leave the plots for

vegetables, either square or oblong, with the longest side facing the south where convenient, as with most crops there is an advantage in having the rows of vegetables run north and south, so that the sun may shine equally on all sides of them. Late Peas in very hot weather might form an exception to the rule, especially if several rows be placed side by side, which, however, is not the best way of growing them. The question as to the number and width of the garden walks must in the main be decided by each individual occupier, who will no doubt be guided by the extent of his garden, which if it be small may simply be intersected by a path down the middle, or if large a path round the outside in addition; but no more walks than are absolutely necessary should be made, and those should be well formed, so that they may at all times be dry.—E. H.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

November 8.—Sowing Sangster's No. 1 Early Emperor, Little Gem, and Laxton's Alpha Peas; potting Lily of the Valley, and shifting herbaceous Calceolarias into 6-in. pots; planting some Cherry and Rose trees; putting in Asparagus to force, keeping it at from 58° to 60° night temperature: making hot-bed for Rhubarb, Lily of the Valley, and Hyacinths in a dark shed; putting glass over Lettuces for the winter; taking up Salvia patens and getting all Dahlias into a cool, dry cellar; making mounds of soil ready for planting Cucumber plants; giving Strawberries a good dressing of burnt earth; making ground ready for Mint; clearing dead leaves off bedding Pelargoniums, &c.; pruning espalier Pear trees; getting pit cleaned and whitewashed for early spring Cucumber plants; carefully keeping lean-to Cucumber-pit not higher than 68° at night and from 70° to 72° by day with fire-heat, as more warmth seems to induce disease.

Nov. 9.—Potting Japan Lilies in peat and sand, and putting them into cold pits; planting Boxedgings; taking up and potting Hollyhocks—any sorts that have not struck freely; arranging Heliotropes, Pelargoniums, and Primulas, and keeping the temperature for them at 50° to 53° at night, to induce them to flower; nipping blooming shoots off Calceolaria cuttings: emptying rubbish yard, and carting its contents to garden to dig in.

Nov. 10.—Sowing Early Long-pod Beans; planting various kinds of Pears, Plums, and Apples; putting all Cauliflowers not fit to cut in cold lean-to house; putting in plants for forcing, consisting of Roman and other Hyacinths, Narcissi, Van Thol Tulips, Persian and other Lilacs, Briers, Azaleas, Roses, Rhododendrons, Rhodoras, Vermilion Brilliant Tulip, Deutzia, and Pinks; tying up Lettuces and Endive in frames to blanch; protecting Globe Artichokes; getting Cauliflowers coming in too fast hung up in cellar; getting leaves into forcing pit for bulbs, &c.

Nov. 11.—Planting a border of Lily of the Valley; getting Peach trees in pots into their places; top-dressing them with two parts loam and one part manure, ramming the soil down hard; tying espalier Pear trees; laying Broccoli; painting Vines and loosely tying them up ready for starting; fumigating all Orchid houses for thrips and fly; putting litter over Lily of the Valley in pots; top-dressing pot Vines with bone-dust, loam, and manure; beginning to manure Asparagus beds; getting broken glass repaired where necessary; repairing all verges; clearing Ivy from Yew trees where it reaches the branches.

Nov. 12.—Sowing Mustard and Cress regularly in boxes; potting Roses, Solomon's Seal, and White Pinks; putting Seakale in bin in Mushroom shed to blanch; plunging some Lilies and Hyacinths in bottom-heat; beginning to nail east and west wall trees; placing protectors over Lettuces, Endive, Violets, Stocks, young Cauliflowers, &c.; covering up a little Seakale so as to be able to get at it in frosty weather; also Jerusalem Artichokes, so as to enable them to be got up during frost; washing Gardenias; giving Cucumbers a top-dressing of turfy loam and sand; soiling over the Asparagus beds; ridging-up vacant ground; pruning and tying Raspberry canes.

Nov. 13.—Potting Lilacs, Guelder Roses, Laburnums, Ribes, and Azaleas—plants that have been prepared for forcing; putting Schizanthus and Humeas in 8-in. pots; potting plants of Spiræa Ulmaria for forcing; putting Mimuluses into flowering pots, also Mint and Tarragon and Balm for forcing; planting Horseradish; nailing Plum trees; wheeling leaf-soil on to herbaceous borders; plants in flower—Chrysanthemums, Primulas, Cinerarias, Monochætum ensifolium, Heliotrope Florence Nightingale, Begonia parvifolia and B. incarnata, Cytisus, Erica hyemalis, Gesneras, Mignonette, scented, scarlet, and Lady Plymouth Pelargoniums, Fuchsias, Coleus, Gardenias, Narcissi, Schizostylis, Amarantus, Scutellarias, and Stocks.

Glasshouses.

Azaleas.—The length of time during which these plants may be had in flower has induced many growers to vary their treatment, so as to very much prolong their season, instead of letting them come in through the influence of sun heat during April and May. Such plants as were purposely retarded to bloom late should now have completed their growth and formed flower-buds; and plants that have been hitherto the earliest to flower should at once be put into heat, but in no case ought they to be hurried by submitting them to too much warmth, or allowed to stand far from the glass overcrowded with other plants.

Winter-flowering Heaths.—We often hear complaints made by those who annually buy in a stock of these winter-blooming Heaths, that they are very liable to die off towards spring; this may in some measure be due to the treatment they have received at the hands of the growers with a view to give the plants a vigorous, luxuriant appearance; but it also is often caused by their being crowded together amongst other plants, where they labour under a deficiency of air and light. Heaths cannot bear being kept too warm, and where greenhouses are kept through the winter at a temperature of 45° in the night, Heaths of the above description are sure to suffer unless they are all but touching the glass in the lightest pits or houses it is possible to erect. The luxuriant profusely flowered condition that well managed plants of this character have when sent out by those who grow them largely for sale is simply the result of two or three years' high and careful cultivation; the balls of earth the pots contain are complete masses of densely packed roots that, if ever allowed to suffer from want of water, are sure to be so affected as to cause their almost certain destruction. This points to the necessity for continued watchfulness as to their requirements for water, and where there is an inclination to do anything with them beyond simply flowering and then discarding them, as is generally done with Hyacinths, constant attention to their wants is indispensable. The stock should be looked over every ten days, and where the slightest trace of mildew can be found the plant should be dusted with flowers of sulphur, or syringed with water impregnated with sulphur; where either are used it is necessary to be particularly careful that neither the sulphur nor the water in which it is held in solution gets to the roots.

Lachenalias.—There exist many varieties of these, the flowers of which range from white, rose, orange, red, and yellow to the colours of the well-known L. tricolor, with its combination of red, yellow, and green. Where a sufficient number of plants are grown they may be had in flower over a lengthened period by forcing some, allowing others to come on in an ordinary greenhouse, and retarding another portion in cold frames, with just as much protection through the winter as will keep them from being frozen during hard weather; for though nearly hardy it is better not to let the frost reach them. The following varieties are very useful, viz., L. fragrans, the flowers of which are red and white, sweet-scented; L. pustulata violacea, violet; L. quadricolor, orange, red, and yellow; L. tigrina, white; L. tricolor, one of the freest bloomers, coming in early; L. pendula, red, tipped with yellow and green; this with me grew stronger than most of the others. There are several more, but these fairly represent the family.

Chrysanthemums.—These, where not already indoors or under protection of some kind, should at once be got in. Now when the buds are considerably developed, the plants collectively are less liable to receive injury, even when put with ordinary greenhouse stock, than when only just about formed. Wherever they are placed give them as much air as can be admitted with a due regard to the other plants associated with them. Where some of the latest-flowering kinds are grown with a view to keeping them back as late as possible, there will be no difficulty in doing so where there is a house with a north aspect with a full volume of air night and day, except where there is an appearance of frost. These will not open their flowers before the latter part of December, when, if the buds are well thinned and all suckers kept removed from the base of the plants, they will be alike useful for general decoration and cutting.

Eurya latifolia variegata.—There is not a greenhouse in the country, large or small, into which this plant might not be introduced with advantage. Its handsome leaves—about the size of those of an Orange—are richly variegated with creamy white. It is a good grower, and has an equally pleasing appearance in a small and large state. Though nearly hardy on a wall in the south of the kingdom, it seems most at home as a greenhouse plant. It is now cheap enough, and is easily propagated; points of the shoots of this summer's growth taken off now with three or four joints, and placed in a cold pit or house, covered with bell-glasses, and kept moist, will have their base well callused over in the course of three months, when, if put into a little heat, they will root immediately; they can then in the spring be potted off and grown on.

Euonymuses.—Although these are quite hardy in most parts of the country, and the majority of them ultimately grow to a large size, they are among the most useful plants for pot culture that can be grown, especially the variegated kinds; the ease with which they can be propagated and grown admits of their being used in quantity for decorative purposes in halls, porches, verandahs, and window boxes for the winter, in all of which positions their bright handsome foliage almost supplies the place of flowers. Cuttings taken off now made of the young shoots, and inserted thickly in pots plunged in ashes and kept in cold frames through the winter, just protected from frost, will root in the spring with or without artificial warmth, but if assisted with a slight hotbed then it will much help the season's growth. When well rooted they should be planted out in rows in well prepared, free soil in a light situation, in which, by the end of the second summer, they will have made good bushy plants ready for potting off. Any of the erect-growing variegated forms are suitable for the uses here recommended.

Shrubs for Forcing.—These, which may now be taken up, should include Rhododendrons, selecting for the purpose the early-blooming kinds. Quite equal to these Rhododendrons are the Japanese varieties of Azalea mollis, which are great improvements in size and substance on the Ghent sorts; they are better adapted for using as pot plants in this way than for blooming out-of-doors, as, except in the most favoured localities, they have a disposition to flower before danger from spring frosts is over. The hardy Azalea (A. amœna) and the Ghent varieties are excellent forcers. Kalmia latifolia, Laurustinus, the double-flowered Prunus, Deutzia gracilis, Lilacs, and the Guelder Rose all answer well for this purpose, and are very serviceable in helping the supply of ordinary greenhouse plants. They are especially to be recommended where the means at command in the shape of houses and pits solely devoted to plant growing is insufficient to keep up the requisite supply, as in many places during the winter season there are mid-season and late Vineries and Peach houses where such plants can be placed out of the reach of frost and snow, and where they will be slightly encouraged to come on into bloom, and be in a better condition for introducing to the forcing house than if left out in the open air.

Flower Garden.

Carnations and Picotees.—See that all newly-potted plants are kept moist at the roots as soon as new rootlets are formed, and the frame light should be rather more tilted as the plants seem to become established. In a fortnight or so after potting, the lights, when the weather is fine, may be removed altogether. Fumigate the plants after they are established, as a preventive of green fly. There are several methods of fumigating low frames, but the following plan is the simplest: A square hole is dug in the ground, half of it under and half of it outside the frame, and deep enough to hold the fumigator. The latter is merely a cylinder made of sheet iron, with a grating at bottom; it is about 7 in. wide and 1 ft. deep. Some burning coal or coke from a neighbouring furnace is placed in the bottom, and over it is laid the Tobacco or Tobacco-paper. The apparatus thus arranged is dropped into the outside hole, and pushed quite under the frame. When the latter is sufficiently filled, the fumigator is pulled out, and a sack or mat is placed over the hole. It is best to destroy the fly after it does appear by fumigating, but in the case of a small number of plants they may be dipped in soft-soapy water sufficiently strong to kill it.

Fruit.

Vines.—Late-planted young Vines that have grown vigorously, as they generally do, will still require artificial warmth in combination with free ventilation, in order to ensure thorough ripeness of wood. Even in the best of seasons it is sometimes difficult to get such Vines to

ripen, and as the present one has been all but sunless, it will at once be seen how necessary a continuation of artificial warmth is. Such Vines may now have the growth that was allowed to run, to induce greater root-action, cut off; but in its removal carefully guard against injury to the foliage on the main stem, that being an important factor in the plumping up of the fruit-buds. Late Grapes, particularly Lady Downes, will still be the better for having the temperature kept up to about 65°, and the surplus growth on these should also now be removed, as light and air are essential as regards the good preservation of the fruit so long as it remains on the Vines. Grapes that have been ripe for some time, and which are keeping but indifferently on the Vines, through the surroundings being damp, ought to be cut with pieces of the wood and placed in bottles in a dry room. In the case of Grapes that are to be ripe in April, or early in May, the Vines will at once require to be started. "Slow and sure" should be the motto; so for the present be content with keeping the house closed without applying fire-heat. Prior to starting see that the inside borders are well moistened through with water at a temperature of 80° or 90°, and outside borders should have a thick covering of litter or bracken put on them to exclude frost, and shutters or tarpaulin to throw off wet. If, as is in many instances the case, the earliest Grapes are had from pot Vines, these too should be now started, and, though bottom-heat is not essential, a slight warmth, such as that produced by 2 ft. or 3 ft. in thickness of Oak leaves, will assist the earlier starting of the Vines; and even if allowed to root into the leaves, as they will do as the heat declines, such rooting is beneficial.

Vegetables.

Soils vary much, for whilst some are benefited by annual trenchings, others prove more productive if trenched only at intervals of two or three years. As a general rule all kinds of light soils will pay for trenching annually, and the extra labour expended in doing it is saved by freedom from weeds in summer and the ease with which the crops can be sown, hoed, earthed, &c. The trenching of heavy soils is a more formidable matter, but, as a set-off to this, it is not so frequently necessary. When it is done there should always be worked in with it a large amount of cinder ashes, lime scraps, or any material likely to render it more open and porous. Clayey soils are much improved by the addition of burnt soil, and whenever there is likely to be any fallow, advantage should be taken of it to burn a portion, which is easily done by collecting on the ground a heap of brushwood, hedge clippings, or a few faggots, in fact anything that will create a body of fire wherewith to start the soil. Burnt earth for all adhesive soils is simply invaluable. The present is also as suitable—and, as there is no work particularly pressing just now, perhaps as convenient—a time as any during the whole year for clearing up soil-yards, rubbish heaps, and vegetable refuse of every description, all of which gives profitable employment for frosty mornings. Take advantage of dry weather to finally earth up Celery, and bracken or long litter should be in readiness for protection; for if severe frosts sets in it will soon be seriously injured, as, like all other vegetable crops this season, there is a want of solidity and ripeness through lack of sunshine. Cauliflowers and the earliest Broccoli will need to be examined daily for the purpose of bending the leaves over the foliage to prevent injury from frost. Surplus heads can be retarded both by partial lifting (a gentle heave with a fork) or by entirely removing them to a cold shed. Cauliflower plants that are to be wintered in frames or hand-lights must still have the fullest exposure to the weather; the lights should only be put on when sharp frost appears certain. Slugs may be kept from injuring them by an occasional dusting with fresh lime, wood ashes, or soil. Lettuces, Endive, and other saladings intended for winter use will now all need partial protection, such as that afforded by cold pits, orchard houses, or hand-lights. Forcing operations must now begin in earnest; Asparagus, Seakale, and Rhubarb will now force freely, but they will doubtless require more time than usual, seeing that the roots were so late in maturing their growth. Herbs of all kinds usually required in winter can be had by planting a few roots in pots and placing them in a temperature of 45°.

Variegated Kales.—These during winter are very effective when well grown, and their leaves are very useful in decorations when little else of the kind is procurable. There are several races, or "strains," of curled and variegated Kales, Melville's being one of the best, while some prefer what is called the "triple curled perennial" sort, which is said to be a cross between the "Perennial Woburn Kale" and the "annual variegated" variety. In colour these plants vary from white and creamy yellow through all the shades of rosy-lilac to a deep purple, while in form some varieties, such as the Palm tree Kale, or some of the best forms of curled Kale, are very graceful, and even the green forms of these deserve a place either in beds or isolated masses along with the variegated kinds. Kale seeds should be sown in little beds during the summer, say either in June or July, and when the seedling plants are large enough they should be transplanted into rather poor soil, which, by somewhat restricting their luxuriance, induces them to sport into different shades of colour. Much larger quantities should be transplanted than are required for decorative purposes, as all seedling plants do not develop colour variation. Late in the autumn, or after the bedding plants have been cleared off, all the best forms of Kale may be removed from the reserve ground and planted out according to their colour and size, care being taken to transplant with good balls of earth, and to tread them gently but firmly in their new quarters. Some fail to succeed with variegated Kales, by not planting them out in the beds early enough, and the sooner this is done after the ordinary bedding plants are removed the better, before the earth has wholly parted with its summer heat. Our illustration shows some of the forms assumed by these plants; but their chief beauty consists in their colours, which, when lit up by gleams of winter sunshine, are certainly very beautiful at a time when bright colours of any kind are sure to be appreciated. They can either be used alone or grouped along with the Conifers and other dwarf shrubs used in filling up the bare patches of earth left after the summer display of bedding plants is over, and their prevailing colour being lilac or lilac-purple, it follows that golden-leaved shrubs, such as variegated Hollies, Euonymus, or Thujas, are most effective for contrasting with these plants, and to these Golden Yews and Box may be added for the sake of variety.

Group of Variegated Kales.

Lettuce Banks.—The most remarkable thing now in our market gardens is the Lettuce banks planted up with some of the tenderer Cabbage kinds that stand the winter. In open places, especially where the soil is at all wet, it is usual to round up beds on which both Cabbage and Cos Lettuces are planted, as in this way less moisture is retained around the roots than is the case when they are planted in flat ground. Lettuce banks have a sharp incline, without special reference to aspect, the important point being to secure shelter. In order to obtain this the banks are thrown up under Apple trees, Currant bushes, &c., and in some cases small Laurels are planted closely along the tops of the ridges and in such a manner as to project over the bank. These Laurels afford good protection, as they retain their foliage all through the winter. Under such circumstances, a Lettuce crop is got off early, and the soil can be again partially levelled to furnish a crop of dwarf Beans, or other summer produce. The best market Lettuces appear to be the Paris White Cos, Bath Brown Cos, and Grand Admiral Cabbage, and in some cases the Leyden White Dutch Cabbage kind has also given great satisfaction. Of course a hardy constitution is of the first importance, but the bank plan of culture is advantageous to half-tender kinds that are larger and more acceptable for table. The demand for Lettuces depends for popularity very much upon the character of the weather; in cold periods they are little sought after, but in warm weather there is a great demand for them.

Protecting Salad Vegetables.—With the aid of the French cloches, or hand-lights, or garden frames of any description, or those improved shapes of movable contrivances, of which we see so many advertised illustrations, all kinds of salads can be easily protected from very hard frost. Beds of Lettuce, Endive, Radishes, Watercresses, and many other things might be covered with them and preserved for a long time. It is preferable, however, to leave these plants without cover as long as possible, or to have the sashes or tops of hand-lights off at night, even though it be frost, for 6° or 8° of frost will injure nothing in this way at this season. It is further on that these things get tender, and it is therefore best to keep them as hardy as possible. Coddling and too early protection are the bane of those useful necessaries of life. Where there is a quantity of cloches or hand-lights together in one lot, a piece of frigi domo or canvas stretched over the whole in hard frosty times is better than leaves.—C.

Potatoes.—Having seen numerous remarks in GARDENING ILLUSTRATED from time to time about Potatoes, it may not be uninteresting to some of its readers if I make a few observations on the subject, which are the result of experience gained this season in the north, within two miles of the centre of Sheffield, in fact. I may say at the outset that my soil is light, with a porous bottom. Magnum Bonum Kidney has, with myself and others, averaged 3 lb. per root, and many tubers have been exhibited weighing from 1 lb. to 1½ lbs. I consider Magnum Bonum much superior to Scotch Champion, which is more suitable for a field crop, requiring to be planted 3 ft. apart each way. This wet season the tops of Champion in my garden were 6 ft. long and as green as grass the second week in October, though planted on Easter Monday. The average was not more than 2½ lb. per root, though some few roots had 20 Potatoes weighing 4 lb. International Kidney is the finest second early Kidney I ever saw, my crop producing 3 lb. per root, and the habit of growth is such that one lift of the fork brings them all to the

surface. I planted 1 lb. only of Woodstock Kidney, and the produce was 20 lb., but they spread about very much, and if not careful you spoil many tubers with the fork. They are however, more floury when cooked than International. Schoolmaster turned out a good average crop, and were ready in August, but I notice this peculiarity about it, that many tubers have what may be called knobs on them, which detract from their appearance. Snowflake turned out many fine large tubers, but I notice that they are a long time coming to maturity. Mine were planted in March, and not ready until the last week in September. I consider the best flavoured Potato I have grown this season to be Myatt's Prolific, which were ready the second week in August. Lastly, I may state that all these varieties were free from disease in my garden, as I did not find a dozen diseased tubers altogether, and these were in the Scotch Champions. —BURNS.

MIXED FLOWER BORDERS.

MOST of the plants in herbaceous borders will shortly be in a condition to have their tops removed; this is necessary for appearance sake, but is not justifiable upon any other grounds. The tops, although they may have no vitality in them, afford protection to the roots and dormant buds that lie thickly about the crown just under the soil. When the old flower-shoots are removed, the crowns sometimes suffer in two ways, first, from the absence of shelter that would be afforded were the tops allowed to remain, and also from another and often more serious cause. In many cases the stems are hollow, and when these are cut at 1 in. or 2 in. above the ground, they get filled with water down to the bottom, right to the very point where the buds are formed that are intended for the ensuing year's growth. To inflict as little injury as possible in this manner care should be taken in the first place never to remove the tops from a plant whilst there is any vitality in them; for, until dead, they must impart strength to the roots, and when in a condition for removal, they should never be cut so close as is generally practised. Instead of severing them near the surface leave them 8 in. or 10 in. high; so treated they will not be an eyesore. In the case of anything that is at all tender a little dry Fern or litter may with advantage be placed round and over the crowns.

All weeds should be removed by hand and the ground raked; but in places where there are yet any leaves to fall from deciduous trees, anything in the shape of mulching over the entire surface should be deferred until all the leaves have fallen and can be cleared off, as if the mulching is put on whilst the leaves are yet falling, it is afterwards a difficult matter to clear them off. In far the greater number of gardens many more bulbous plants than are usually seen might, with advantage, be grown. Their distinct forms and pretty colours are an interesting and pleasing feature during the spring months.

Nothing in their way can be more beautiful than the varieties of Erythronium (Dog's-tooth Violet); those who intend growing these should procure E. giganteum or grandiflorum, a fine red variety; E. alba major, a very large-flowered pure white, much superior to the old white variety; E. americanum lanceolatum (yellow), a very distinct and desirable kind; E. atro-roseum, a deep rose-coloured kind; E. purpureum majus, very large mauve purple flowers; E. giganteum album, splendid white, bearing eight or ten flowers on a stalk; E. giganteum flavum, fine golden-yellow. Either grown together in a bed or in good-sized patches at the front of the herbaceous border, these plants have a charming effect, not alone for the beauty of their flowers, but their handsome mottled leaves are very attractive; they should be planted without delay. Hardy kinds of the Ranunculus, such as the Turban varieties, may now be planted in situations where the soil is dry, but the more valuable sorts should not, except in very favourable positions, be planted yet, as they are apt to suffer from wet by lying too long in the ground.

Where a succession of handsome hardy flowers is held in estimation, single Anemones should be largely grown, the plants, from their compact habit and the continuous brilliant coloured blooms which they produce, being almost without a rival; the single scarlet variety is most effective, commencing to flower, in a mild season, during the first month in the year. Anemones like a moderately rich, free soil, and if grown in clumps in the herbaceous border should occupy a front position, on account of their dwarf habit of growth. Such subjects as Sweet Williams, and fine varieties of Foxglove, that were sown in the early part of the season and afterwards transferred into nursery beds, may, if the weather keeps open, and when grown in soil of such a nature that they will move with good balls of earth, be now planted in the borders where they are to flower; but when these conditions do not exist, or the plants are small and late, it is better to defer this work until spring, or they might suffer if a hard winter was to set in early.

A very pleasing effect may be produced in spring by planting large masses of Snowdrops, Crocuses, and Daffodils in the Grass in distant parts of lawns, in Grass plots in out-of-the-way corners, or in front of shrubbery borders, and under trees. These may be either planted in patches or dispersed 6 in. or 8 in. apart over the available ground. The places chosen for plants of this kind should not be in too close proximity to the dwelling, as the tops ought not to be removed in the spring until after they are dead, which, in a very prominent position, would be unsightly. Where any of the above plants are to be so arranged, they should be planted immediately. Crocuses and Snowdrops may be put in by making holes with an ordinary dibber, covering the bulbs with a little loose soil; for Daffodils, holes must be made with a spade, but whichever way the planting is effected, it can with ordinary care be done even on Grass without having an unsightly appearance.

Double Canterbury Bells.

Double Canterbury Bells.—Now is a good time to sow seed of this biennial, but seed sown in March will secure large massive plants that will produce several spikes of flowers, and display the beauties of one of our finest hardy border plants to the best advantage. The seed is small, and may, if plentiful, be sown in a warm spot in the open ground, but it is much safer to sow it in shallow pans or boxes placed in a frame or on a shelf in the greenhouse, as in the latter case all the seed will probably germinate and an abundance of plants be secured. Seed sown now should also be sown in pans, and when well up be picked off into small pots or boxes to be finally planted in the open ground in March or April. When those from the spring sowing are large enough to handle conveniently, prick them out into some shady spot, and keep them watered until the plants are well rooted. From that time they may safely be left to take care of themselves until September, when they should be transplanted into their permanent places in the flower borders, and so treated will not only get well established before the winter arrives, but will also develop their blooming crowns for the next year. This constitutes nearly all that it is needful to say as to the raising of a seedling stock of these Campanulas, better known as Canterbury Bells. They may be classed into three sections—single flowers, as seen in the old-fashioned single Bells; doubles, as found in the stout massive flowers, in which two, three, and even four bells seem to be compressed into the outer one; and duplex flowers, as seen in the calycanthema forms, in which one bell grows in the other, and the combined two resemble a cup standing in a saucer. The single varieties, as of old, are still to be had, but no one would care to be dependent upon these only who have once seen the beautiful products of a fine modern double and semi-double strain, and which will also produce some single flowers. Whilst the old single strains comprised only white and blue colours, the modern strains include nearly a score of hues, inclusive of white, lavender, mauve, several shades of purple, pink, rose, salmon, and also blue. The duplex strains have have hitherto been chiefly confined to white and blue, but other colours are now being introduced. It is a curious fact in relation to this section that whilst the seed of the white form is of a pale hue, and the seed of the blue form is of a dark tint, the seed of the double and semi-double forms of all colours is the same, viz., a glossy brown. The habit of the latter section is compact and good, the plants when in bloom ranging from 18 in. to 24 in. in height, forming perfect pyramids of flowers. From frequent experience I have found that these may be lifted and placed in pots even when in full bloom without injury. If to be used for corridor, house, or conservatory decoration, it would be best to lift the plants and pot them into 6-in. pots early in May; this would enable them to get well established before the blooming period. The calycanthema section usually exhibits both a taller and a looser growth, and should be planted in borders behind the double and single kinds. Plants from seed sown now would flower next May twelve months, and those sown in March a few weeks later.

Laying Out Flower Beds.—Variety in form of flower beds is next in importance to a variety of plants. But how to invent or lay out a dozen or a hundred, and have no two just alike, seems to puzzle most persons, judging from what we see in villa plots and grounds of more pretension. The square, circular, heart-shaped, diamond and star are all well enough under certain circumstances, but their frequency in small gardens leads one to think the inventive powers of amateurs, in this direction at least, are rather limited, or are not put to the test for the want of a proper incentive to produce a diversity of forms. Our books on gardening are also full of labyrinthian designs for flower beds, which would require a skilled geometrician to carry out to anything like perfection. For my own part, I never could see anything to admire in one of these carefully-designed flower beds, laid out a geometrical nicety, like the patch-work bed-quilts of our grandmothers. The free-and-easy natural splashes of a bed here and there among the Grass, or an entire border under cultivation, always look best to my eye, whether right or wrong. I had to form some beds on a small lawn, and the next question to be decided was the shape of the beds, and how they should be laid out. Of course, I could resort to the rule and square, and by providing a few hundred small stakes, the design might be made sufficiently plain for the guidance of ordinary workmen; but I dispensed with all this kind of apparatus and merely took a large rope and coiled it around upon the Grass in the form that I wished the bed to be when finished. With a sharp spade the soil was cut by the side

of the rope, and the design was complete. Then I proceeded to the next, and so on until all were laid out, after which my men could go on and dig up the sod over the entire bed without any danger of making a mistake. A rope of 1 in. or 1½ in. in diameter, laid upon a close-cut sod or bare soil, will give one a better idea of how a bed is going to look when finished than the best drawn design upon paper, or any number of stakes driven in the ground. Then one can twist the rope this way and that, coil and uncoil, until the design just suits the eye and fits the spot where the bed is to be made. A pretty design on paper may not always fit in among trees and shrubs and look as well as a person might "think it would." By discarding the square and rule and using the rope, a person can give free scope to his imagination in designing suitable forms of beds; and the more they depart from the usual geometrical styles the better.

ANSWERS TO QUERIES.

3489.—**Keeping Plants from Drying up.**—One of the chief objections to a brick flue in a greenhouse is the tendency it shows to induce a hot, dry atmosphere. This evil is less seen where hot-water pipes are used, as there, although heat is still as strong, or even stronger, it is obtained in a more healthy manner. One thing which strikes us is the fact that for the air to be so very dry that the plants are dried up much more heat must be furnished than is necessary. Whilst the weather is open and dry no fire-heat should be given in an ordinary greenhouse. It is when damp is prevalent or severe frosts prevail that fire should be used, and that regularly, as but one night's frost may destroy all the results of a year's labour. But even let the weather be what it may, it is not well to force a heat of more than 45° at any time, although on a warm, sunny day this may be for a short time exceeded. 40° at night will do admirably, and there are no greenhouse plants that will not do well in such a moderate temperature. If the plants are dried up in such a temperature as this indicated, the flue must be nearer to the pots than is desirable. If the roots get dry, water freely, and if the air of the house seems too dry give air, and put on the flue a shallow zinc tray filled with water. This will emit moisture sufficiently to keep the air from burning. It is, however, most probable that the fire-heat given is excessive, and should be somewhat moderated.—A. D.

3458.—**Quick-growing Trees and Shrubs.**—Plant a row of Limes next the road, then a row of Cupressus Lawsoniana to form a screen. If the Limes get too large cut them back or remove them if the Cupressus form a sufficient blind. The following are suitable for lawn planting: Berberis Darwini, Hollies of various kinds (especially Hodginsi, Silver Queen, and Gold Queen), Evergreen Oak, Acacia inermis, Acer Negundo variegatum, Ailantus glandulosa, Weeping Birch, Weeping Ash, scarlet, pink, and white Thorns, Spiræa ariæfolia, Venetian Sumach, Cedar of Lebanon, Picea Nordmanniana, P. Pinsapo, Abies canadensis, Thujopsis borealis.—E. H.

3460.—**Climbers for Porch and House.**—Plant a collection of Ivies on the house wall, leaving out the strong-growing green-leaved kinds. Between the Ivies plant Clematis Jackmani hybrids. Against the porch plant a Gloire de Dijon Rose, a Honeysuckle, and Clematis flammula, and let them all grow up together. The following will be a good selection for the border: Snowdrops, Crocus, Tulips, Hyacinths, Daisies, Forget-me-nots, Primroses, Pansies, Pinks, Clove Carnations, Sweet Williams, Anemones, Columbines, Canterbury Bells, Michaelmas Daisies, Sedum spectabile, Sweet Peas, &c.—E. H.

3484.—**Treatment of Old Fig Trees.**—Fig trees in the open air require to be so placed that it gets the full benefit of the sun during the summer. If grown in a partially shaded situation the wood does not acquire the maturity necessary to enable it to carry a crop of fruit; neither does the Fig like rich or well manured soil, but delights in sandy or calcareous soils, where it makes short-jointed wood, which ripens up well by the autumn. The only pruning that the Fig needs is to cut all weakly branches or thin them out where at all crowded, so that sun and air can play freely amongst them. In the case of an old barren tree, we would take it up in March, shorten back the long, strong roots which have got too deep or too far from home, thin out the branches, and plant in quite poor soil in the sunniest place at command. Mortar rubbish in quantity is an excellent material for mixing with the soil. The young fruit is formed by the autumn, and then as soon as the leaf falls mat up the tree safely, stuffing in plenty of litter amongst the branches. The second crop will form in the spring.—J.C.B.

3406.—**Improving Lawn.**—Hand-pick the lawn at once, both Daisies and Dandelions will pull out with the roots entire now the land is so soft. It the latter breaks off instead of drawing out, place a large spoonful of salt in the hole. If the Grass is strong and coarse manure will not help it. Persevere with the roller in mild weather. I have never known it to fail if done often enough.—E. H.

3469.—**Wintering Ranunculuses.**—The root of the florists' Ranunculus is a tuber, or rather is tuberous and not a bulb. It is not well to plant them now, but rather in February, and even then it is desirable to protect the bed in which they are planted to some extent from severe frosts and heavy rains, but it is not an absolute necessity. Roots yet left in the ground should be lifted at once and dried off, then be stored in a dry place until planting time in February. If left in the ground all the winter the roots may entirely disappear. The Ranunculus requires good soil; in fact, rich soil; the loam stiff, but well pulverised by frost, and intermixed with rotten manure and sand. The roots should be planted only when the soil is fairly dry, and will fall to pieces when a handful is held up and allowed to drop.

—— Take them up carefully and store each kind in dry sand in a flower-pot, placing them in a cool situation, such as a cellar. The roots will bear a considerable amount of drying without losing their vitality, for we have known some to grow freely after they had been kept out of ground for two years.—B.

3470.—**Worms in Cinerarias.**—We fail to perceive what connection there can be between the flagging of your newly potted Cinerarias and the small white worms beneath the pots. It would seem most probable that owing to the plants having been left unpotted for a couple of days some of the small roots had died, and hence the flagging of the plants after repotting. It is most probable that keeping the plants in a cool frame and shaded when the sun shines would soon bring them round. If, however, there is further evidence of these small worms, the best thing will be to give a watering with lime-water—made by putting about 1 lb. of hot lime into a gallon of water, and allowing it to stand until it is quite clear. It can then be used when required.—A. D.

—— If you have worms in the soil turn out the plants and pot in fresh soil; this will not check them, as they have been recently potted. All that you have to do is to water moderately for a time until the roots get well hold of the soil, and keep the plants free from frost, but quite cool. The Cineraria likes a moist, cool atmosphere, and the soil should be kept in a moist condition without watering heavily.—B.

3474.—**Insects in Pansies.**—It is very common of the Pansy to collapse in summer, especially when the weather is hot, but this has usually been attributed to shanking or rot in the stem. How produced, however, no one seems to understand. The affection in the stem is always just at the junction with the root. The small white insects may have something to do with this disease, but it is most probable that they are but the inevitable accompaniments of decay in the plants. We have found that autumn-planted Pansies are rarely affected, whilst those planted in the spring will die at a wholesale rate. A little Tobacco water or lime water would probably soon kill the insects, but it is doubtful whether the plants would be saved, as the insects are more likely to be the effect than the cause.

3481.—**Neapolitan Violets.**—You cannot have the soil too good for the Neapolitan Violet, but it must be rather a natural goodness, and not an artificial one. The Violet likes a good fibry loam of two-thirds with the other third of well decayed manure. Strong plants should be in 7-in. pots, and now be full of robust foliage and have strong crowns. The plants should have been potted ere now, but if old, they should have a shift into larger pots, or, failing that, have 1 in. deep of the soil removed and fresh added. The proper place is in a cold frame standing upon a bed of ashes, the leaves almost touching the glass. The lights should be tilted both in front and at back unless the weather be very severe or the wind be rough and strong.—A. D.

3476.—**Camellias Dropping their Buds.**—This arises from various causes, but in most cases it will be found that, providing dryness of the soil is not the immediate cause, the roots have got into a more or less unhealthy condition. It is a curious fact that a weakly plant will generally set a large number of buds, although these will be small, and the plant being deficient in vital force, they will drop almost as soon as the plant is placed under cover in the autumn. All that can be done in such a case is to examine the drainage by turning the plant carefully out of the pot. Should the drainage appear at all defective, replace it with fresh material. Water carefully during the winter, allowing the soil to become dry, and then giving enough to thoroughly moisten it through. In the spring, just as fresh growth is appearing, work away as much of the old soil as possible with a pointed stick without injuring the roots, and replace in the same sized pot, working in some fine well sanded peat round the old ball. Keep under glass until growth is made, and then turn the plants out in a shady sheltered situation until the middle of September.—J. C.

3477.—**Planting Xanthoceras sorbifolium.**—In order that this shrub may thrive properly, some little care must be taken to prepare the soil for its reception. Where the natural staple is heavy and cold, it is better to remove it entirely, taking out quite a good square of soil and replacing with good fibrous, somewhat sandy, loam, to which may be added a little leaf-mould. The plant in question may remain where it is, protecting it a little in hard weather and planting afresh in the beginning of March.—C.

3463.—**Culture of Oleanders.**—Whoever wishes to flower Oleanders well must induce them to make a free and early growth and mature the wood by full exposure to sun and air. Oleanders delight in strong solar heat in combination with copious supplies of water at the roots. A good sound fibrous loam, adding to it a little leaf-mould, is the best soil for them, and the pots should be well drained. Shift in March and keep the plants tolerably close and warm for a time, but expose them to full light, and ventilate freely all through the summer. About the latter end of August turn them out for three weeks in the open air.—J. C. B.

3483.—**Bare Places on Bowling Green.**—We presume that the turf will be trod upon again early in the year, in which case it would be of little use to sow Grass seeds, and the only way will be to procure fresh turf and make up the bare places. This must, however, be done at once, so that it grows into place by the early spring before dry weather arrives. If you can give the turf a rest, that is to say, if the Grass is not likely to be much trodden upon during the summer, you may sow Grass seeds in the spring, taking care to well sweeten the soil by turning it up roughly before sowing.—J. C.

3473.—**Blue Hydrangeas.**—We have no experience of H. cyanoclada, but as it is advertised by a respectable firm we should suppose it to answer the description. We are acquainted with a blue Hydrangea which has preserved its colour for fifteen years, as do the young plants taken from it, and M. Lavallée, of Segrez, tells us that he has a fine blue Hydrangea which he calls cyanea, and which he asserts is much hardier than the common variety.—J. C.

3475.—**Rose on West Wall.**—Niphetos is not a suitable Rose for a wall; it is not a vigorous grower; and is more valuable for pot culture, beds, &c. Gloire de Dijon, Madame Berard, Cheshunt Hybrid, Jean Rosenkrantz, Climbing Duke of Edinburgh, Climbing Devoniensis, Lamarque, or Solfaterre, will be found much more suitable for the purpose. If the winter is very severe the long blooming wood of the last three must be protected with matting, &c., otherwise the frost will much injure the trees.—WILLIAM WALTERS, *Burton-on-Trent*.

3402.—**Pruning Gloire de Bordeaux Rose.**—This Rose is similar in rapid growth to Gloire de Dijon, and must be pruned sparingly. Cut out next March all the weak, ill-placed, and crowded shoots, and shorten

back the long well ripened wood to the first vigorous eye, taking care not to shorten more than is necessary. The roots should be protected and strengthened with a good mulching of manure during the winter, which may be dug in towards March, and with this treatment the plant should flower well next season.—WILLIAM WALTERS, *Burton-on-Trent*.

3465.—**Pruning Gloire de Dijon Rose.**—As the tree has made so much wood very likely it is owing to hard pruning last spring. All vigorous growers of this class must only be slightly shortened, cutting away all unripened and misplaced wood. See remarks on pruning Gloire de Bordeaux Rose (No. 3402) which will equally apply to Gloire de Dijon, Madame Berard, and others of the same rapid growth amongst Teas and Noisettes.—WILLIAM WALTERS, *Burton-on-Trent*.

3485.—**Climbers for House.**—Cotoneaster Simmondsi, C. microphylla, Cratægus pyracantha, Cydonia japonica, C. j. rosea, Escallonia macrantha, Euonymus radicans variegata, Garrya elliptica, Magnolia grandiflora, Ligustrum japonicum, and Berberis Darwini. Ivies alone in variety will have a pretty effect on a red brick house.—E. H.

3400.—**Rose of Sharon Under Trees.**—Yes; it will grow well under trees if not too much shaded and deprived of light and air. I recently saw a quantity in a nursery near Nottingham thriving well, planted out under the shade of some Apple and Damson trees.—WILLIAM WALTERS, *Burton-on-Trent*.

3465.—**Evergreens for Chalky Soil.**—Arbutus Unedo, Evergreen Oaks, Portugal Laurels, common Laurels, Box, Yews, Berberis stenophylla, Furze, Japanese Privet, Abies excelsa, Cedrus Libani, Cupressus Lawsoniana, C. sempervirens, Juniperus hibernica, Picea balsamea, Thuja occidentalis, Pinus austriaca.—E. H.

3461.—**Shrubs for Screens.**—To blind the road plant a belt of Cupressus Lawsoniana, zigzag fashion, not in a straight line. To form the screen round the Oaks plant chiefly such shade-loving subjects as Hollies, Boxes, Yews, Evergreen Oaks, Barberries, Aucubas, Japanese Privets, with a few common and Portugal Laurels, introducing also here and there a deciduous flowering shrub, such as a Lilac, Laburnum, Ribes, Syringa, Guelder Rose, &c.—E. H.

3479.—**Winter Cucumbers.**—If a temperature at night of from 60° to 65° can be secured, if there are means of getting a bottom-heat of 75°, then Cucumbers may be grown in the house with Coleus, &c. Moisture in the atmosphere can be obtained by damping floor and walls. Insects, such as greenfly and thrip, must be guarded against, and a sprinkling of fresh soil should be added over the roots weekly; it tends to keep all sweet. Train the Cucumbers within 18 in. of the glass, and when the short days come don't prune or pinch too much.—E. H.

3478.—**Stones for Rock Plants.**—We do not think that the stones in question would be likely to prove injurious, although we should certainly prefer a more porous material. The object of stones is to provide efficient drainage, and this they will do, whether they contain minerals or not.—J. C. B.

3475.—**Tea Roses on Walls.**—We think that Gloire de Dijon would be better for you than Niphetos, which is tender and requires more warmth than the generality of Teas. Where only one kind of Rose can be grown let it be the old Gloire de Dijon, than which nothing is more beautiful, and which flowers so freely and for so long a period.—J. C.

3462.—**Dendrobiums not Flowering.**—All the time the plants are growing they should be kept in moist heat, but as soon as growth ceases turn them out for a rest into a cooler structure, or place them at the coolest end of the house, and keep them rather dry. The best time to pot is just as growth commences, and the best soil for them is three-fourths peat and one-fourth Sphagnum.—J. C.

3259.—**Wintering Roses in the West Riding of Yorks.**—In a warm border in an exposed situation I never take up my Tea Roses, as I think the longer they are established the better they are able to resist frost. Mine are on their own roots, and I protect the roots with rough litter and the tops with Fern. They have been planted ten or twelve years in the same border. I have also a Banksian Rose.—HARTSIDE.

3469.—**Wintering Ranunculus Roots.**—I take up the roots when the foliage turns brown, and when dry, pack in dry sand in a box and keep in a dry place till the middle of February, when I plant again. This plan has answered well with me for several years. Mine have been packed away more than two months.—J. C., *Dorset*.

3471.—**Dandelions on Lawns.**—Constantly cutting the crowns of Dandelions will kill them, but their destruction will be much hastened if a large spoonful of salt is placed on the wound when the crown has been cut away. Watson's lawn sand used in the same way has the same effect.—E. H.

3480.—**Climbers for a Greenhouse.**—I hope "S. L. B." will obtain what he desires; but he aims high. Perhaps the following may suit him: Jasminum Sambac fl.-pl., Rhynchospermum jasminoides.—E. H.

3467.—**Trellises for Screens.**—If the trellis is not more than 5 ft. high, and if it is formed with wires strained along horizontally, and does not touch the Pear or Apple trees, I think they will do as little harm as anything that can be substituted for them. Of course, if we grow too much on the land, something must suffer.—E. H.

3486.—**Plants for Pillars.**—Habrothamnus elegans will soon cover the pillar, so would Plumbago capensis; better take out a tile and plant it out. The question as to the border is somewhat vague. Camellias, Acacias, or a mixed collection of winter and spring flowering plants may be either planted or plunged in pots, or be stood on the surface of the border, and might, if rightly done, give satisfaction in either case.

3459.—**Pyracantha not Flowering.**—Prune it hard back, and place some fresh soil and manure round its roots. It has become stunted; new life must be infused into it. This the pruning will do by turning the sap into fewer outlets, and cutting away those that are blocked up.—E. H.

3312.—**Pine-apple.**—*J. Burford.*—If you get a number of GARDENING for April 26, 1879, you will find an engraving of a variegated Pine-apple.

3401.—**Gnats' Bites.**—"Butterfly" asks for a cure for the painful bites of gnats and midges. There is nothing better than Eau-de-Cologne. When cover shooting, I always carry a small flask with me and occasionally moisten my forehead, ears, and neck with it, as it is a preventive as well as a cure.—SPORTSMAN.

3538.—**Vines in Windows.**—*Philflora.*—If your window is a light and sunny one, you might possibly succeed. It would be best to get a well-ripened Vine from a nursery, and plant it in a prepared border outside, and bring the stem in through the brickwork or woodwork. Black Hamburgh would be the best kind.

3539.—**Wintering Geraniums.**—I have some hundreds of Geranium cuttings struck last month in an old Cucumber bed, from which the heat is entirely gone. Can I keep them during the winter without removing them by placing a frame and lights over them?—W. J. H. J. [Yes; if you can keep frost and damp from them. They will need no water unless the soil gets really dust dry. Then water without wetting the leaves, and leave the lights off for a few hours during sunshine. Keep dead leaves picked off.]

3540.—**Lily of the Nile.**—What treatment should I give to a healthy Lily of the Nile plant during winter, as regards watering, &c.? Will it require more protection than a spare room without any fire? And what should I do about the young plants which are coming up round the plant? It is in an 8-in. pot and has not flowered yet.—AMATEUR. [Keep it in the window during mild weather, but during frost it must be put in a warmer place. Sponge the leaves now and then to clear them of dust, and keep the soil moist. Leave the young plants till the big plant has flowered; then remove them and pot them, or plant them out in good soil.]

3541.—**Forcing Rhubarb in Dark Pits for Christmas.**—*M. T.*—Put 3 ft. of long stable manure into the pit and well tread it down, covering it over with a few inches of garden mould; then get some strong Rhubarb roots and place on the bed, and cover them up to their crowns with light mould or leaves. Close the frame, and cover over with mats or straw. A lining of manure round the pit will be an advantage. If some leaves can be mixed with the manure they will help to retain the heat.]

3542.—**Wintering Geraniums, &c.**—*Vaga.*—You may winter Geraniums, Fuchsias, and Myrtles in a greenhouse so long as you do not allow the thermometer inside to fall below freezing point.

3543.—**Mildewed Plants.**—*W. H. B.*—Give plenty of ventilation, and let each plant stand free of its neighbour. Water as little as possible, and this always on the morning of a fine day. Sprinkle the leaves affected with flowers of sulphur.

3544.—**Returfing Cricket Ground.**—Will turf which has become very yellow by having been cut and rolled for some time recover itself? and how soon? I should also be glad to know when procuring new turf how thick it should be cut?—FIDELITER. [The turf will doubtless recover in spring if laid at once; 1½ in. or 2 in. is the proper thickness to cut turf for laying.]

3545.—**Cardoons.**—*J. M.*—These are of no use for culinary purposes unless properly blanched. They require protection in winter. The best way is to raise them from seed every year.

3546.—**Wintering Heliotrope.**—*Hereford Square.*—It is hardly possible to safely winter Heliotropes in cold frames. Put them in the window of a warm room, especially if you wish them to preserve their foliage.

3547.—**Coral Moss or Fern.**—*Asa Rebbew.*—You probably mean the fruiting Duckweed (Nertera depressa). It requires a moist, warm place during winter. It will flower and fruit in spring plentifully. In summer it will, of course, do in the open air in moist soil not too much exposed to the sun.

3548.—**Worms in Manure.**—*Inquirer.*—Apply a small shovelful of salt and the same quantity of soot to each large barrow-load of manure. Well mix it and turn it over two or three times. Let it remain in a heap for two or three weeks before use, turning it over every three or four days, and adding a little more soot each time. It may then be applied to the ground.

3549.—**Stephanotis.**—I have a Stephanotis in the stove in a pot. It is twined up the roof, and now it darkens the house very much. Can I take it down and twine it round stakes inserted in the pot and put it in a temperate house during winter, and when shall I put it back again?—A. B. T. [You may twine it round the stakes, and so long as you do not move it to a house where a very low temperature is kept, it will be all right. Move it back in March, and train it up the roof again.]

3550.—**Antigonon insigne.**—I have several plants of the above raised from seed about ten months ago. They are now from 4 in. to 7 in. high, and have only the two first leaves. They look very healthy, but appear to have been just the same as they are now for several months. What ought I to do to make them grow? In cold weather I have kept them in the sitting-room, in hot weather in the attic.—A. R. [Keep them in a warm window if you have no greenhouse, and put a bell-glass over them.]

3551.—**Sawdust for Covering Bulbs.**—After potting Hyacinths, Lilies, Tulips, Crocuses, &c., and placing them in a cold frame, bedded in ashes, would sawdust answer the same purpose as covering them with ashes to exclude the light?—WALTER H. [Inverted flower-pots are the best, over the hole of which may be placed a piece of slate, and the whole be covered with ashes. Cocoa-nut fibre and Hops are good materials for covering bulbs, but we have a dislike to the use of sawdust for all gardening purposes.]

3552.—**Wintering Carnations.**—I have some choice plants of Tree Carnation, such as Souvenir de la Malmaison, in small pots. Would a cold frame be a good place to winter them in? Will they be injured by frost?—R. R. [A greenhouse would be the best place for them, but they may be safely wintered in a cold frame if the pots are plunged to their rims in ashes or Cocoa-nut fibre.]

3553.—**Palm Fronds Cut Down by Frost.**—I am told if the fronds die down, although the roots are quite sound, and crowns sound and green, they never throw up fronds again. Is this the case?—J. B. [Palms which lose all their leaves seldom succeed afterwards. By placing them in a warm, moist atmosphere, however they may recover.]

3554.—**Crown Imperials.**—*C. J.*—The Crown Imperial may be grown and flowered in any loamy soil forming a flower border, but to do it justice, and to ensure a fine bloom, it should be planted in a deep rich soil well drained. If the soil is not rich it must be made so by the addition of a good dressing of well-decomposed manure. A good coating of manure should be laid about the plants during the winter, as it will give them a little protection during severe frosts, and benefit the bulbs. The Crown Imperial is one of those plants that, when once planted, require to be let alone and remain undisturbed for years. Strong bulbs do not always flower the first year after planting.

3555.—**Preserving Window Shrubs.**—*A Learner.*—The pots should be plunged in ashes or Cocoa-nut fibre in the window boxes. These should be watered only when dry, and not at all in frosty weather; always water with cold water. In spring plunge the pots out in the garden and give them plenty of water during summer. A top-dressing of some good artificial manure will benefit them if done early in summer, or a little liquid manure occasionally.

3556.—**Trees and Shrubs.**—What are the best trees and shrubs to plant in a garden now?—CONSTANT READER. [All trees and shrubs may be planted now. What kind of a garden do you want them for?]

3557.—**Egg Plants.**—*Edith.*—These should be raised from seeds every year. Sow in March in a warm frame, pot into small pots of rich soil, and finally shift into 6-in. or 8-in. pots, or plant out in a frame or out-of-doors in June. To grow them well they want a warm, moist temperature.

3558.—**Vines in Pots.**—Should Vines in pots be taken under cover during the winter, or left in the open air?—A. K. [Take them into a cool house until they are wanted to be started if you can do so.]

3559.—**Roses in Small Greenhouse.**—Will the fumes from a brick flue, which I only light to keep out frost from Geraniums and Fuchsias, injure Maréchal Niel and Gloire de Dijon Roses? Also what treatment does the Maréchal Niel require? It is a young plant in a 8-in. pot.—D. LAW. [Unless you make the flue very hot it will not injure the Roses. Train the shoots of the Roses out thinly, so that they can get plenty of light and air, and do not prune them. See article on Tea Roses in last week's GARDENING.]

3560.—**Caterpillars on Geraniums.**—*W. J. B.*—We know of no preventive only that of well digging ground and apply a good dressing of lime, letting it lay roughly through the winter. When the caterpillars first appear hand-picking should be resorted to, and they may then be greatly checked, if not eradicated.

3561.—**Double-bearing Raspberries.**—*W. R. P.*—There is a kind of Raspberry in called the October Red, which produces fruit in June from suckers made the previous autumn, and in October from suckers made during the summer of the same year.

3562.—**Taking up Gladioli Roots.**—*L. H.*—It is not absolutely necessary to take up Gladioli roots every year if they are growing in well-drained soil. They may be wintered by having a few inches of ashes placed over their roots. Choice sorts, however, are safest when lifted and replanted in spring.

3563.—**Jerusalem Artichokes.**—*Ecossais.*—If planted in February or March in rows 3 ft. apart and 2 ft. from set to set in the rows, and in deeply dug, well-manured soil, and in an open, sunny situation, they must succeed. If the ground is very light, mix some well pulverised clay with it. The Artichoke is liable to run to top in very light soil.

3564.—**Planting Fruit Trees.**—*Breese Hill.*—It is not necessary to put bricks under fruit trees where a sandy subsoil exists. You need not fear the roots going down to the sand if you do not plant the trees too deeply, and keep the surface soil well mulched with manure.

Names of Plants.—*G. M., Aberdeen.*—Tussilago farfara grande; sponge the leaves to get rid of the insects——*F. A. S.*—1, Solidago (species); 2, Santolina incana; 3, not recognisable; 4, Fuchsia virgata.——*Fairfield.*—Gloria Mundi.——*Ashstead.*—Stachys lanata.——*G. A. N.*—1, Leycesteria formosa; 2, Sparmannia africana.——*Edward Pears.*—1, Aster multiflorus; 2, A. ericoides; 3, A. Novæ Angliæ pulchellus; 4, A. Chapmani; 5, A. pulcherrimus.——*H. C.*—1, Aster Novæ Angliæ pulchellus; 2, A. Amellus.——*J. H. A.*—Agrostemma coronaria.——*Teeford.*—Apple Nonpareil Russet, in use from October to February; Pear Marie Louise, evidently grown on a standard or bush tree; in use during September, October, and sometimes November.——*Richmond.*—Eccremocarpus scaber.——*C. C. S.*—Pholidota imbricata; Begonia Weltoniensis.——*Rev. W. S.*—Hibiscus syriacus.——*Mrs. L., Bray.*—Lycium barbarum.—*A. C.*—1, Saxifraga hypnoides var.; 2, variegated Sedum; 3, Sedum acre; 4, Sedum carneum; 5, Saxifraga hypnoides.——*Samphire.*—*G. G. K.*—We think not; we should not advise you to use it.——*Saxon*—1, Adiantum cuneatum; 2, Pteris serrulata cristata.——*J. C.*—Large leaf, Escallonia macrantha; small leaf, Cotoneaster microphylla; simply nail the shoots to the wall.——*Margaret.*—We can form no idea as to the names of your plants from such small crushed-up pieces you send us.——*S. R.*—Achillea Ptarmica fl.-pl.——*Constant Reader.*—Red Musk (Mimulus cardinalis).——*Ped.*—Calliopsis tinctoria, Chrysanthemum coronarium fl.-pl., Viscaria oculata.——*W. H. B.*—Campanula carpatica.——*W. H.*—Send blooms of the May-flower you allude to.—*H. D. H. D.*—A seedling Grape Vine.

QUERIES.

3565.—**Holly for a Christmas in Canada.**—I should feel obliged if any one would tell me the best way of sending some Holly to Canada for Christmas, and would it be possible to send a small tree of Holly about two seasons' growth, the weather in December being very cold?—FRED.

3566.—**Brussels Sprouts Seed.**—Will any one tell me how to save seed of Brussels Sprouts? I have a very fine strain.—OLD SUBSCRIBER.

3567.—**Raising Australian Plants from Seed.**—I should be glad if any one would tell me how to sow

and grow the following plants, seeds of which I have received from Queensland. A short description of what kind of house they will be suited to eventually will also be of service : Barkleya syringifolia, Tristania conferta, Leptospermum flavescens, Brachychiton Bedwilli, Ficus macrophylla.—SUBSCRIBER, *Lymington.*

3568.—**Slugs and Worms.**—In a work on "Our Garden Friends and Foes" I find the following : "I have found that a most potent means of destruction is ammonia, which kills the slugs without damaging the vegetation on which they feed. I take some solid ammonia, and dissolve it in water, so as to make a very weak solution, and when the shades of evening are beginning to fall I water the ground carefully, taking care to give every inch of soil its dressing of ammoniated water. The effect is rapid and certain; the slugs that are yet in their subterranean dens come hastily to the surface, and there lie paralysed by the potent fluid." Can any reader of GARDENING give me any information of the quantity of ammonia required to fetch out the slugs without injury to the plants?—AMATEUR.

3569.—**Woolly Aphis on Auriculas.**—I find that the roots of my Auriculas are smothered with what is, I suppose, woolly aphis ; what am I to do with them? It is too late to repot, is it not?—SNAPDRAGON.

3570.—**Fir Trees for Screens.**—I shall be obliged if some reader will inform me what Firs to plant to form a thick shade, 10 ft. or 15 ft. high. Also the quickest growers for such a purpose, and that will stand clipping; or if any other tree would be better than Fir?—W.P.P.

3571.—**Grass under Trees.**—Can any one recommend a good Grass seed for sowing under the shade of Plane trees? I have been recommended a mixture of Poa nemoralis, Poa nemoralis sempervirens, and Poa trivialis, which was also highly recommended by the seedsmen who sent it to me, but the result was a failure. If any one can recommend anything likely to succeed, I should be greatly obliged. Grassy turf is wanted, not Ivies, Periwinkles, &c.—G. J.

3572.—**Jasmines not Flowering.**—I have two white Jasmines which grow to a great size every summer; although they have been cut back considerably every autumn, they hardly flower at all; aspect south, in a border. How can I make them bloom?—LEWISHAM.

3573.—**To make Pelargoniums Flower.**—I am informed many gardeners use an acid to force Pelargoniums to flower. Can any one inform me what it is?—J. B.

3574.—**Keeping Roots of Scarlet Runners.**—Would some one kindly inform me how to keep my Scarlet Runner and Canadian Wonder Bean roots until planting-out time?—ENQUIRER.

3575.—**Violets not Flowering.**—What is the reason that Violets form seed vessels instead of flowers? Several sorts have been tried in my small-walled garden, and though the plants look well till the end of summer, when the leaves turn yellow in sunny spots, no flowers ever appear. Different parts of the garden have been tried with the same result.—F. L. L.

3576.—**Pentstemons, Auriculas, and Polyanthus.**—Will any one oblige me with the names of six of the finest hybrid Pentstemons, distinct colours? six of the most distinct varieties of florists' Polyanthus? and six of the finest alpine Auriculas, distinct colours?—BURNS.

3577.—**Figs under Glass.**—Will some reader give best dimensions for a span-roof house, say 30 ft. long, for growing Figs? Would it be best to plant in the ground or in pots? What are the best kinds to grow? What soil do they like?—FIG.

3578.—**Passion-flower not Blooming.**—Can any one inform me what is the reason that any Passion-flower has never bloomed for four years? I have planted it in my greenhouse ; the soil is rather dry (in the garden it is chalk). The plant reaches now to the top of the greenhouse, but no bud has ever appeared.—E. GIBERNE, *Epsom.*

3579.—**Acorns for Picture Frames.**—Will any one tell me what would be the best thing to use for sticking Acorns on to cardboard or wood? also for sticking the Acorns into the cups? Last year I tried glue, but after they had been hung up in a warm room some time, the Acorns fell off. I have seen some pretty frames made of Acorns, but could not tell what to use besides glue. What could I stain them with, as ordinary wood stain runs off them? I should like to stain them dark brown?—NIL DESPERANDUM.

3580.—**Best Carnations.**—Will some one give me the names of a dozen or more Carnations which do not burst when expanded, and need no tie to keep them in shape? I want the best in each section, which have the above good habit, as well as a few Selfs or Cloves of the most distinct kinds, which will also keep their shape. Is there a good yellow Carnation or Picotee which does not burst?—BURNS.

3581.—**Soil for Plants.**—Will some practical reader give me a list of composts for plants? I am sure it would be most appreciated. What is the best substitute for peat? It is out of my reach, and so is silver sand. In last week's number it is stated that sea sand can be used without injurious effects to plants. Will any other of your practical readers give further advice on this subject?—X. Y. Z.

3582.—**Sea Sand for Plants.**—Will "H. B. S." (3330) say if the sea sand which was used in lieu of silver sand was prepared in any way to free it from the salt which it contains? as the gardeners tell us that this property makes it most injurious to plants, and that few will survive being brought into contact with it.—E. G.

3583.—**Tree and Plants for Boggy Soil.**—Will the Liquidambar flourish in a river-side plantation where the soil is boggy and wet? the surface of the ground being from 12 in. to 18 in. only above the water level in summer, while in winter it is occasionally submerged altogether. The plantation is principally cpmposed of Alders, with a few Birch, Ash, and Willow trees, all of which do well. I am anxious to introduce some varie-

Uses of Lawn Mowings.—Can any reader inform me if mowings off my lawn are of any other use besides making manure? I have a very large lawn, and I generally get two cart-loads of Grass from it once a week, and am at a loss to know how to make use of it.—G. C., *Tonbridge.*

Hollow Celery.—Can any one tell me why my Celery is hollow? It is the Sandringham White. Another sort in the same garden is all right.—USHURIUS.

gated and light green summer foliage, and especially some which will show rich colour in autumn. I am also desirous of introducing some of the more showy wild flowers, both British and foreign, which would be adapted to make themselves at home among the somewhat luxuriant undergrowth. Primroses, Cowslips, Wood Anemones, Oxalis, Caltha palustris, Daffodils, and Narcissus do very well, and some of the moisture-loving species of Ferns, but it is too wet for wild Hyacinths. I think there must be many kinds of plants which would luxuriate in such a situation, but as I have been very unfortunate in losing many which I have attempted to grow, I should be glad to know whether any of the bulbs advertised by Dutch nurserymen would succeed in such a situation. Only those things should be tried which love shade and will bear drip from overhanging trees.—A CONSTANT SUBSCRIBER.

3584.—**Scale on Peach Trees.**—Can any one tell me how to get rid of scale on my Peach trees? I have tried various so-called remedies without success.—N.

3585.—**New Roses.**—Will some one give me the names of six of the best and most distinct new H. P. Roses raised or sent out during the last six years, and which can be considered a real improvement on older varieties?—BURNS.

3586.—**Insects in Mushroom Bed.**—I had a Mushroom bed which has a fine show of Mushrooms, but directly they are seen above the mould they are eaten off by slugs, and possibly, woodlice. I have caught several slugs, some of which were very large, others small and black, by means of Cabbage leaves distributed about the bed, but this fails now.—J. H. B.

3587.—**Planting Trees near a Neighbour's Garden.**—In the garden next to mine on the west side my neighbour is planting tall forest trees, such as Poplars, Chestnuts, &c. I should be glad if any one acquainted with the law could tell me if he has a right to plant them up close to my fence, or is there any law to compel him to keep them a certain distance away therefrom?—A SUBSCRIBER.

3588.—**Club in Cabbages.**—I am much obliged to Mr. Taylor for his information respecting the club in Cabbages (Ans. 3114) while in the seed bed, but I should be very grateful for a remedy to prevent the clubbing after planting out.—E. T. H.

POULTRY.

CHOICE AND MANAGEMENT OF STOCK IN SMALL SPACES.

IN deciding what breed of fowl should be kept consideration must be given to the situation of the house and run. If they face N. or N.E., the latter the very worst possible aspect for poultry, only a very hardy kind of fowl can be kept with any chance of success, and Cochins will be best for the purpose. They are excellent layers, their eggs having a very fine flavour ; they will bear a great amount of cold, and they are less liable to disease than many other kinds. But they are not ornamental. Their greatest admirers can hardly praise them on the ground of good looks.

Brahmas, perhaps the favourite fowl of the present day, at any rate the most fashionable, for there is a fashion in poultry as well as in flowers, require more warmth than the Cochins, but they bear confinement well, are very large and weighty birds, capital eating and good layers, though the eggs of pure bred Brahmas are often small for the size of the bird. The chickens require a good deal of care and attention at first, and indeed till full grown, if they are to be brought up to exhibition standard, and an amateur should always keep this standard before his mind, whether he exhibits or not.

Hamburghs do well in confinement, and if quantity rather than size and quality is desired in the matter of eggs they are good fowls to keep. They lay as freely as Bantams, they never want to sit, they are very ornamental, and fairly robust.

If the house and run face to the south or south-east, and really beautiful birds are required, then keep black Spanish. They are profuse layers during eight months of the year, the eggs being very large and finely shaped, and the hens will not sit. But unless they can have a warm, sheltered aspect, secure from rain and cutting winds, it is no good attempting them. Anyone keeping black Spanish fowls must be prepared to take a good deal of trouble over them ; but they are worth the trouble.

Game Fowls and pure bred Dorkings will not do well in confinement.

Having selected the breed to be kept, keep to that one kind, and let the birds be pure bred, but not too highly bred, *i.e.*, too much bred in.

Never overcrowd the run. Beginners will hardly believe the ill effects of overcrowding. Disease breaks out in spite of most careful tending, and the number of eggs falls off at once. More eggs will be obtained from six young hens that have sufficient space than from twelve that are overcrowded.

Be very particular in choosing your cock bird. He should not be younger than 18 months, or kept after he is 3½ years old, and the special points peculiar to his breed should be well defined.

Chickens should be hatched as early as possible in the year. With proper care they will stand very severe cold, but it is hardly possible to get fine large birds from chicks hatched during very hot weather. The sun injures them much more than the cold, provided they are kept from the wet and sheltered from strong N.E. winds.

Pullets, if hatched in February or early in March, will probably lay at five months old ; but those hatched in May or June will very likely not commence laying till early in the following year ; consequently they have to be kept a long time before they become remunerative. It is often difficult to get a broody hen early in the year. If they have been encouraged to continue laying through their moult they are too debilitated to commence laying again till late in the spring, so that care should be taken to keep one or two hens sitting through their moulting time. They may have ducks' eggs, for young ducks can be brought rapidly forward in the autumn, or they may be kept sitting on a few nest eggs for five or six weeks. If this plan of resting the hens is adopted they will generally be ready to sit early in the year. Spare no pains to make the birds as tame as possible, and accustom them to being handled frequently, especially if they are intended for exhibition.

It is a good plan to go into the fowl-house occasionally after they have gone to roost, and to take them from the perch. They soon learn not to be frightened, and are quite quiet and gentle under the operation. The advantage of this is found when the hens are sitting. There is a very prevalent idea that the fiercest hens make the best mothers. Perhaps where the fowls run wild, and the chicks have to be defended from hawks and cats, this may be so ; but in confinement the more tame and gentle the hens are the better. Those that get excited whenever anyone goes near them are sure to break some of their eggs while sitting, and to trample some of their chicks to death afterwards. *(To be continued.)*

HOME PETS.

Goldfinches.—I have had for some years in an unheated greenhouse an aviary, in which I have been in the habit of keeping canaries, goldfinches, linnets, and such small birds as I could procure ; but I have never been successful in keeping goldfinches for any length of time. This season a very favourable opportunity offered of my being able to procure a lot of young goldfinches which had been sprigged on birdlime. Knowing them to be delicate birds, I put them into good-sized store cages, where I paid them much attention, and in such a position I knew they would not worry themselves by flying about as in so large a structure as the aviary. In spite of my best attention, many succumbed. But some twelve or fourteen were promising, and after hardening for about a fortnight, I transferred them to the aviary, where they did not improve, for one by one they became muffy and lumpy, and I have lost nearly all. I gave them Hemp and canary seeds, green food occasionally, and a sufficiency of water at all times. Can any one suggest the cause and remedy?—W. H. B.

Canary Not Singing.—I have a canary four years old this season which has always proved himself an indefatigable songster, but has not uttered a sound since the commencement of this moult, now more than three months ago. Can any of your numerous readers tell me the cause and remedy, if any? It is apparently in good health, and is in splendid plumage.—F. C.

Different Birds in One Cage.—Can any reader inform me if two canaries, one linnet, one goldfinch, and one siskin would do together in a cage 2 ft. by 1 ft.? also give a few hints as to their management?—J. B.

Blackbird Turning White.—Can any reader explain why a blackbird, about four years old, in perfect health, and lively as before, should have become, at its recent moulting, white on the head, having some white feathers on neck and on wings? Is it a disease, or what?—LANARK.

THE HOUSEHOLD.

Preserving Tomatoes Whole.—Will some one please give me a recipe for preserving Tomatoes whole without their being sweet? We have a good many ripe and wish to commence at once.—E. B. K.

Bottling Tomatoes.—Can any one tell me how to preserve Tomatoes for sauce? Is there any way of bottling them whole?—M. C. H.

Clouted Cream.—Will any of your correspondents kindly give plain directions for making the ordinary Devonshire clouted cream?—C. W.

Preserving the Winter Cherry.—Can any one give me a recipe for making preserve of this fruit (Physalis alkekengi)?—LOUIS C. D. F.

VIBURNUMS, OR GUELDER ROSES.

THE Viburnum forms one of the most important families of hardy shrubs, and scarcely ever a plantation is made without a Viburnum of some kind being used in it. There are both evergreen and deciduous species, the first being represented by the well-known Laurustinus, and the second by the Snowball Tree or Guelder Rose. The Wayfaring Tree (V. lantana) of our hedges is also included in this family. As a rule, the Viburnums do not succeed well near towns where the soil is wet and clayey, but in loamy soils in the country air they grow and flower luxuriantly. In Windsor Park, for example, there are large clumps of the Laurustinus, which, during the winter and early spring months, are masses of creamy-white blossoms. Some of both evergreen and deciduous kinds are grown by florists and gardeners in pots for greenhouse decoration in winter, and admirable plants they are for the purpose. The flowers of the Laurustinus, which are plentifully produced on bush or standard plants, may easily be had at Christmas, and they are much whiter than those produced out-of-doors, whilst the Snowball Tree (Viburnum Opulus), when grown in the form of neat bushes, yields abundance of large snowy white balls of blossom early in spring. Well-drained soil and pure air are all that are needed for the well-being of the various members of the Viburnum family. The kind we now figure—

The Dahurian Guelder Rose (V. dahuricum)—is a hardy deciduous shrub, which, in May and June, is covered with umbels of beautiful white flowers. It is a plant which is easily multiplied by means of cuttings made of tolerably firm wood, and inserted in peat soil under a cloche or hand-glass, or the young soft shoots may be taken off early in the season and struck indoors. As soon as they are rooted, they should be re-potted; and when they have become established, they may be placed outside in some shady spot, taking care to plunge the pots; young plants thus raised will be sufficiently hard and woody to be wintered outside without shelter. This Viburnum is not particular as to soil, but those that are light and damp and rich in organic matter suit it best. It forms a somewhat spreading bush, from 6 ft. to 8 ft. high, and has grey downy branches. The berries are oval-oblong, five-seeded, at first red, but when fully ripe in September black and somewhat sweet scented. It is a native of the Dahurian Mountains, and was introduced as long ago as 1785. Among other deciduous kinds the best may be described as follows:—

The Large-headed Guelder Rose (Viburnum macrocephalum) forms a large bush or low tree, covered all over with coarse, starry, scurfy hairs. It is a native of the north of China, and was introduced in 1844 by Mr. Fortune, who speaks of it thus: "This noble species is found in all the gardens of the rich in the north of China, and there is a tree of it growing in a garden on the island of Chusan at least 20 ft. high, which in the month of May every year is covered with its snow-white blossoms." He also adds that when it is grafted on the wild form of the species it blossoms on small plants in pots, and is then not unlike a white Hydrangea, by which name it is known among the Chinese. The flowers

DAHURIAN GUELDER ROSE (VIBURNUM DAHURICUM).
A Hardy Deciduous Shrub; flowers white.

are pure white, and produced in large clusters, which are as much as 8 in. in diameter, not, however, globular like those of the Guelder Rose, but rather pyramidal, each flower being fully 1⅛ in. in diameter, and lasting in perfection for a considerable time. The wild form of the species upon which the Chinese graft the beautiful garden variety displays none of the grand and striking appearance of the sterile-flowered one, which is one of the very finest hardy deciduous shrubs that we possess at the present time.

The Plaited-leaved Guelder Rose (V. plicatum) is a fine hardy shrub growing from 4 ft. to 10 ft. in height, and has glabrous reddish-brown branches. It is found in the north of China and Japan, and was first introduced in 1844 by Mr. Fortune, who says that it is found cultivated in all the gardens of the rich, and forms a bush from 8 ft. to 10 ft. high, which in May is loaded with its globular heads of snow-white flowers, which are about the size of those of the common Guelder Rose. The flower-heads are terminal, and produced in great profusion on the lateral branchlets in April and May, just as the young leaves are unfolding; the flowers are in globular heads, snow-white at first, but just before they fade usually assume a purplish tint. This Viburnum is quite hardy, and a most beautiful shrub when in flower in May.

The Common Guelder Rose (V. Opulus) forms a large bush or low tree, from 10 ft. to 15 ft. high. It is a native of Britain and throughout Europe, in hedges and thickets, in damp and swampy places. The leaves are bright green in summer, but in the autumn they assume a beautiful crimson hue. The flowers are white. The berries are bright red, and, when ripe, in September, very ornamental.

The Variegated-leaved Guelder Rose (V. Opulus variegatum).—This variety only differs from the species in having the leaves variegated white and yellow.

The Indian Wayfaring Tree (V. cotinifolium) is a robust shrub or low tree, growing from 10 ft. to 20 ft. in height, and has grey branches. It is a native of the valley of Nepaul, Kamaon, and the Himalaya Mountains. The flowers are white, tinged with pink when young, obconical in shape, and rather large; they are produced in large corymbs in April and May. The fruit is oval, bright scarlet, and said to be eaten by the people in Nepaul. This kind is rather tender, and requires protection in winter, or to be planted against a south wall, where it makes a fine display, when in flower, in May.

The Laurustinus and its varieties represent the evergreen species, among which the following may be taken as the best:—

The Commom Laurustinus (Viburnum Tinus) is well known as one of the most ornamental evergreen shrubs; it is a native of the south of Europe, from whence it was introduced in 1596. The leaves are of a bright shining green, and the flowers, which are in flat corymbs, appear from November to April, and, in mild seasons, are often succeeded by small dark black berries.

The Variegated-leaved Commom Laurustinus (V. Tinus variegatum) only differs from the common form in having a portion of its leaves variegated with pale yellow.

The Hairy-leaved Laurustinus (V. Tinus hirtum) is more hardy than the common kind, and is a native of Spain and Portugal. Its leaves are oval-oblong, hairy beneath, and on the edges, and the flowers, which appear in the autumn, continue all the winter. There is a variegated form of this which has a portion of the leaves of a golden-yellow colour.

The Shining-leaved Laurustinus (V. T. lucidum) is a native of Algiers and Mount Atlas, and it is less hardy than the preceding. Its leaves are oval, smooth, and of a deep shining green colour above. The cymes, as well as the flowers, are larger than those of the common kind, but seldom appear till the spring, and when the winters are severe, the flowers are killed or never expand, unless in very sheltered places. Of this kind there is a variegated variety.

The Sweet-scented Chinese Viburnum (V. odoratissimum) forms a fine robust bush from 4. ft to 8 ft. high, and in its general appearance greatly resembles the common Laurel. It is a native of China and Japan, and was introduced in 1818 Its leaves are large, oblong, leathery in texture, of a deep, shining green above, pale beneath, and nearly as large as those of the common Laurel. The flowers are white, very fragrant, and produced in February. The berries are oblong, and when young, of a rich red colour, but when ripe, blackish and shining. This Viburnum is too tender for planting in the open border, but makes a fine evergreen for training to a wall.

Greenhouse with Coalhouse or Workshop Underneath. — Recently being at Southsea, a friend of mine had, with a few old lights, two old door frames with doors, a odd lot of scantlings and floor-boards, and about four hundred bricks, built a greenhouse over a workshop. The workshop was sunk 3 ft. in the ground with a flight of steps from ground level to door; the door of greenhouse is at the end, and for want of space the steps to same about 3 ft. high are placed upright. From various queries that I have seen in GARDENING, it occurred to me that a house of this plan could be modified to suit amateur town gardeners. A fireplace or a heating apparatus could be placed in the under part to warm the greenhouse above, or I do not see why the under part could not be used for many other purposes, such as a forcing house. It could be made either with or without light. It would also do for a fowlhouse; in this case if a heating apparatus was wanted it could be placed outside in a small enclosure of corrugated iron. Should an erection of this plan be of any use to an amateur, I shall be pleased to give any other little information that I can. — JOHN BURNELL, *Letchmore Heath, Watford.*

Bottom-heat. — May I be permitted to give a hint to your subscribers as to the formation of a bed for bottom-heat? Some years ago I built a small range of houses for myself, and not being satisfied with the cumbersome way in which the bed is generally formed, viz., with timber or stone, I made an experiment which has answered exceedingly well, so much so, that in the course of my profession I have adopted it in several cases to the entire satisfaction of the gardeners. The plan is simply as follows: I procured some light ⊤ iron cut into lengths for the short way of the bed, set them in an inverted form ⊥ about 12 in. or so apart, and filled in the spaces with malt kiln tiles; these are well open upon the underside, and perforated with fine holes upon the top. Upon this I had laid loose bark from the tan-yard, and then the soil. The whole is easily removed, or a square or two taken out to examine the space below at any time by removing a little of the soil. It takes up so little space in depth, that all the heat must be utilised.—ARCHITECT.

VEGETABLES.

Broad Beans.—These for a very early crop may be planted in November, and as they transplant very easily and safely, when autumn planting is adopted, plant them thickly on a warm raised bed where a little shelter can be given in severe weather; then in February, when the land is in good working condition, lift the young plants carefully, with all their roots intact, and plant in fresh, well-prepared ground in rows 2 ft. apart and 6 in. between the individual plants. Another plan is to sow thickly in a box in January, and place them anywhere under glass, or in any warm, sheltered place and transplant as above stated, pressing the soil firmly about them. These early plantings will, of course, only be on a small scale, for the purpose of securing an early dish or two, as early in February will in most places be time enough to plant the main crop, which may consist of some of the Long-pod section. The Green Long-pod is a good variety for general purposes, and the Seville Long-pod is a very fine Bean. Plant again for succession in April, and the Broad Windsor for the latest crop about the middle of May, in double rows 2 in. to 3 in. deep, and the rows should be 2½ ft. to 3 ft. apart; cover the surface of the soil with ashes as protection from mice, and earth up when about 3 in. or 4 in. in height. When well in flower nip off the tops; this throws back the strength of the plant into the crop, and if, as frequently happens, the young growths be infested with black aphides, it will be the means of clearing them off. When all the pods are picked off, as soon as they are fit for use, it frequently happens that new growths will break away from the lower part of the stem and produce a good late second crop. It may not always be advisable to leave them for this purpose, but it is as well to have the choice of doing so, and they rob the land less in this way than if a part of them be left to get old before being pulled up. The soil most suitable for this crop is a strong, heavy loam, but a fair return may be expected from almost any soil; light land should be made firm before planting.

Early Frame Potatoes.—In the last week in December we mix together about ten cartloads of leaves and stable litter in equal parts. After letting this lie for a week, it is packed firmly 2 ft. deep, in a large frame covered with glass sashes, and heated when necessary by a flue. Soil to the depth of 8 in. is placed on the top of the manure, and the surface when finished is about 2 ft. from the glass. Drills 4 in. deep and 15 in. apart are then drawn and the sets put in 6 in. apart, and covered over to the original level. In a week the manure underneath sends up a gentle heat, which it continues to do until the haulms meet between the rows, With this assistance they grow very quickly to this stage, and as fire-heat is never applied, and the plants not being far from the glass, they do not become drawn or weak. Air is admitted freely during the mild days in March, and they are watered three times—first, shortly after being planted; again, when they are about half grown, and finally about a fortnight before we begin to lift them. The soil in which they are planted consists of about half decayed leaves and the remainder loam. After the Potatoes have been all lifted, the pit will remain empty for a month or two. About the end of August the soil will be turned over, and the whole will be planted with Dwarf Kidney Beans; these will furnish gatherings until near Christmas; then they will be cleared out, the soil thrown on one side, all the decayed manure removed, when a fresh supply will be at once put in, and the Potatoes planted again. This I consider to be making the best of a large frame, as few vegetables are more acceptable than fresh Kidney Beans in November and December, and ripe new Potatoes in April and May. I find Bresee's King of the Earlies better than any of the Kidney varieties.—J. M.

Tomatoes under Glass.—Tomatoes out-of-doors have again in some places proved a failure this season. The wholesale manner in which the half-grown fruits have been attacked and rendered useless has been a serious disappointment to many, and ought to teach us to make the most of every spare corner under glass where a few plants could be accommodated. Many such places may be found where, with a little ordinary care, a crop of fine Tomatoes might be depended upon, as I have never yet seen or heard of a single fruit under glass being attacked with the disease; and, what is more, a good supply is kept up until late in the season. I could have gathered nearly a bushel in Christmas week last year from such places, and hope to do the same again this year. Tomatoes are highly esteemed here; I therefore try to make their season as long as possible. I do not grow many plants, having repeatedly proved that one good plant properly attended to is worth twenty half-starved ones. My earliest supply, from the end of May to July, I get from pots in the early Vineries. I need not describe the treatment which they receive, as it is the general crop about which I wish to speak. Now for this, I have only six plants planted out against the back wall of a late unheated Peach house; they are planted singly between the Peach trees, and occupy the vacant space that will eventually be covered with them as their growth extends. The Tomatoes were planted in May, and were carefully trained and stopped in the usual manner, each plant occupying now a space of 70 sq. ft. or 80 sq. ft. I have not kept an account of the number of fruits gathered, but the crop has been a very heavy one, and the plants promise to keep up a good supply of fruit for months to come. I may safely say that the fruit would average about thirty dozens on each plant, and fine fruit too. I have come to the conclusion that if I have only room for one plant under glass I will never again be troubled with any outdoors, and I would strongly recommend others to do the same. The sort I have grown this year is Hathaway's Excelsior. It is the handsomest and most prolific variety I have ever grown.—H. H.

Autumn-planted Potatoes.—"Gardener," at p. 396, tells us that last year, as an experiment, he planted ½ bushel of Myatt's Ashleaf in October, the tubers being placed 18 in. apart and 2 ft. from row to row, &c., and that better Potatoes could not be wished for, while the same variety planted in spring turned out a complete failure. Now, even supposing this, I beg to ask our correspondent how he can account for such an occurrence? Considering this has been the best season for Potatoes we have had for years, and good sound samples so cheap, and that fully ninety-nine per cent. of these were spring-planted, I conclude your correspondent must have either sadly mismanaged or neglected his spring planting. Otherwise, let me ask, how did "Gardener" and the rest of the world get on for Potatoes before this "new idea" first emanated from a "Country Parson"? Further, a line must be drawn somewhere as to distance in planting; 2 ft. by 18 in. is, to say the least, a most ridiculous waste of ground; 18 in. by 9 in. is sufficient space for any variety of Ashleaf.—THOS. COWBURN, *Sunbury Park.*

Growing Mushrooms.—No time should be lost in getting the materials together for the Mushroom beds, as this is the best time for their construction, in order that they may last through the winter months; a second set should be made in February or March, according to circumstances. The best plan in collecting the droppings is to have a barrow or hamper under cover near the stable to shelter them from rain and empty them every day into a dry shed and spread them out. Add to the droppings (leaving the short litter in) one-third of turfy loam chopped fine and mixed well in, which makes the bed of a more natural character and produces Mushrooms of a more solid texture. Make up the bed by instalments every eight or ten days instead of exhausting the chief growing qualities of the material by drying it. The beds should be from 12 in. to 14 in. deep, and should be trodden as firm as possible; the firmer they are the steadier the heat and the longer it is retained. A trial stick should be put in and when the heat declines to about 75°, pieces of spawn, about 3 in. square, should be inserted from 10 in. to 12 in. apart and about 1 in. deep; then cover the bed with about 2 in. of good stiff loam, beat it down as firmly as possible, and finish off by slightly damping the surface with water and smoothing it over with a clean spade. Again use the trial-stick to ascertain the temperature; and if it should decline, put on some fresh litter from the stable or some hay, to retain a uniform heat and thus keep the spawn in action till it has run well into the bed; when this has been accomplished a good crop may always be depended upon. Avoid violent heat, as it destroys the spawn, and invariably keep the beds covered with litter or hay, so that uniformity in both heat and moisture may be maintained and the bed may continue longer in bearing. When the bed has been in bearing for a time and begins to show signs of exhaustion, carefully remove the litter and give a good watering with manure water made of sheep or cow dung, and used at a temperature of 80°, replacing the litter when the operation is complete. This invigorates the spawn and produces a second crop almost equal to the first.—J. S.

FRUIT.

HINTS ON PEAR TREES.

THE Pear is one of the hardiest and most vigorous of fruit trees; it is capable of adapting itself to soil and situation even better than the Apple. But the situation must be well drained, or there will be a difficulty under any system of management in maturing the wood. On deep dry soil there is no necessity for Pears to be worked on the Quince stock. It is on shallow soils resting on wet cold clays which even when drained cause so much soft spray to be produced that the value of this stock is seen and

Upright Cordon Pear Tree.

appreciated. Much has already been written on the preparation of the soil before planting, and in the necessity of checking the descent of the roots into a bad subsoil by surface-mulching. Summer pinching and thinning the fruit are all important matters in Pear culture, and success will in a great measure depend upon the way in which they are carried out. Pears are especially adapted for espalier training, and a good fruit-bearing tree is more quickly formed than even in the case of the Apple. But as the Apple does not easily assume a pyramidal outline, so the Pear is not readily converted into a dwarf standard. But where espalier training cannot be adopted, the pyramidal is the best and most useful form. The trees should be planted 6 ft. apart, and may be allowed ultimately to attain a height of 8 ft., which will be high enough for a small garden. Of course care must be taken that the tree is properly built up, as in the case of the espalier, if the leaders be allowed to grow too fast, the lower part of the tree will not be well furnished. A wire hoop fixed to three stout stakes will form a very good base for training. When the tree is first headed down after planting, the best and most centrally placed of the young shoots should be selected for the leader and trained up vertically, and the others should be trained at equal distances apart horizontally, and fixed down to the wire to form the base. It is important that a good foundation should be secured to the future tree before the second tier of branches is formed, and this is entirely a matter of pruning and training. Much can be done in summer (about the end of July) by pinching a strong shoot or

drawing its point downwards, and by that means driving the sap into the weaker branches. The leader may be pinched when it has grown about 18 in., in order to throw the strength into the lower buds. At the second winter's pruning the leader must be cut back to within from 6 in. to 1 ft. of the base of the new wood, this depending entirely upon its strength and the strength of the tree generally. Again, the best shoot must be selected for the leader, and the others tied or linked down to the shoots made the previous year. This course must be followed until the tree has attained its allotted size. If it have proved successful, the shape will be a perfect cone, with the points of the branches assuming a weeping or pendent form. In the event of a good selection a small plantation of pyramidal Pears will in the course of a few years turn out to be a most interesting and profitable experiment, involving but a slight expense and an inconsiderable amount of labour, and that, too, of an agreeable kind. Pinching a strong shoot, and drawing its point downwards at the proper time, calls rather for intelligent observation than practical skill, as the term is usually applied, and the man who has had no experience in fruit culture, if thoughtful and penetrating, may obtain as much success as the practical cultivator, especially if the latter be imbued with prejudice and preconceived notions, and too much given to rule-of-thumb work.

The accompanying woodcut shows a capital way of growing Pear trees in small gardens. The trees are kept within bounds by pinching as above described, and if needs be by root pruning. Such trees may be planted 3 ft. or 4 ft. apart, and tied to a single horizontal rail. A hedge is thus formed and space economised.

Pruning Orchard Trees.—After the fall of the leaf is a good time to notice any irregularly of growth in orchard trees, and this may then be rectified in a short time, always bearing in mind that, in the case of large limbs being removed, the wound should be covered with some preparation to shelter it from the weather. Gum shellac dissolved in alcohol, or even cow manure bound on the parts exposed, answers the purpose. A handsomely formed tree is not alone valued for its appearance to the eye; it is in reality more useful, as the crop of fruit is then usually more evenly distributed over the branches.—A. N.

Hardy Grapes.—I have fruited the following collection of hardy Grapes in a glass-covered wall without any artificial heat: Grove-end Sweetwater, Royal Muscadine (the Chasselas Fontainebleau of the French), Pearson's Ferdinand de Lesseps ripened in September, and its peculiar Frontignan flavour was richer than when forced in the hothouse. Buckland's Sweetwater and the Esperione, a black early Grape, ripened in the middle of October, and were finely coloured and better flavoured than when forced early in the houses. Welbeck Black Tripoli, a variety of the Hamburgh, ripened perfectly at the end of October, as well as the Trentham Black.—W. T.

Heavy Pears.—I have gathered some Beurré Bachelier Pears; the weight of one was 1½ lb., six weighing 8¼ lb. One Doyenné du Comice weighed 11 oz., six weighing 4 lb. Six Glou Morceau weighed 4 lb.—S. C., *Dover*.

Training Peach Trees in Houses.—I have a suggestion to make with reference to the planting of trees in a Peach house which may be useful to some of your readers. About eight years ago I built a wooden lean-to, 33 ft. by 10 ft. Against the back were planted three trees, and, of course, it was a prime object to get plenty of sunlight for them. The idea therefore occurred to me to plant the other trees, not so as to be trained against the glass, as is usually the case, but edgewise—say that the house faces the south, then the trees in front of those on the back wall would face east and west. This is done in the following manner: Leave breadth enough for a walk along the front of the trees on the back wall, say 3 ft. wide; place two strong lengths of wood in a sloping position, resting on the ground and reaching a rafter of the roof, to which both are nailed, thus forming the two legs of the letter A. These legs may be about 5 ft. apart at the bottom, meeting at the top, and according to the height of the roof they would be about 8 ft. to 9 ft. high. Place another pair of Λ shaped legs at the front of the house, which, of course, will be much shorter; then run wires from each leg of the higher back A to those of the front A, and you will have two wire trellises 5 ft. apart at the bottom and meeting at the top. Continue these all along the house, and there will be some four or five such double trellises. Now the advantage of planting thus are, first, there is no shade to the back wall; second, the trees can be easily got at on both sides; third, the surface exposed to the sun is nearly twice what it would be if the trees had been trained up against the glass; fourth, a greater number of trees can be cultivated, thus continuing the crop through at least three months, and supplying a variety of kinds. The experience of eight years teaches me that these smaller trees thus planted are as prolific as they can be, and the wood ripens as well as if they had been placed so as to face the full south.—T. R. J.

TREE AND OTHER PÆONIES.

Pæonies, with their crimson, pink, white, and other coloured flowers produced during a great part of the months of May and June, were long great favourites in gardens, although they are now somewhat neglected—probably owing to the fact that they are so large, that in small gardens they would occupy too much room. There are, however, generally to be found, even in gardens of limited size, spots so much shaded that scarcely any flower will thrive in them. In

Fern-leaved Pæony (P. tenuifolia).

such places Pæonies would grow luxuriantly; the colour of their blooms would, in many cases, be even more intense, and they would last much longer than flowers fully exposed to the sun. They may therefore be made useful as well as ornamental, even in small pleasure grounds, although the proper place for them is undoubtedly the fronts of large shrubberies, plantations, or by the sides of carriage drives. Where distant effect is required no plants so admirably answer the end, as their size and brilliancy render them strikingly visible, even at long distances off. Planted on either side of a Grass walk, the effect which they produce is admirable, especially in the morning and at or near sunset, and when planted in masses, as, for instance, in beds in pleasure grounds, they are invaluable for lighting up sombre nooks.

Among the older forms, the best are P. officinalis rubra, rich deep purplish-crimson; officinalis rubescens, double bright ruby, and very fine; and edulis or albiflora, another original species, of which there are several fine varieties. Of newer varieties, the following are worthy of attention: Alba superba, Auguste Van Veert, centifolia rosea, Charles Binder, Duc Decazes, Eugène Verdier, Gloire de Douai, Jeanne d'Arc, lilacina, Madame Margottin, Madonna, Mrs. Hartnell, Prince Charles, pulcherrima, purpurea, The Queen, and tricolor plena. Some of these are of great size and beauty. P. tenuifolia, which we now figure, is not so showy as some of the kinds mentioned, but it is well worth growing.

Tree or Moutan Pæonies are a most important group of plants from an ornamental point of view. They form, as is well known, robust, early spring-flowering shrubs, varying from 2 ft. to 4 ft. and 5 ft. in height, and bearing blossoms of extraordinary size, brilliancy, and beauty. They succeed well in all ordinary garden soils, exclusive of peat, unless found upon a deep dry sub-stratum. Blooming, as they do, early in the year, they occasionally require some slight protection to preserve the blossom-buds from late frosts. I have seen them used with good effect on Grass plots. They have a fine appearance in a mixed border of shrubs. Their blossoms are of various shades of colour, from paper-whiteness to the most brilliant crimson and purple shades, and the plants are of such free-blooming habit, that they become literally covered with their immense blooms during the summer months. They may be transplanted either in autumn or in spring before they make their growth. They are propagated by root-division, by grafting on the roots of the herbaceous varieties, by taking cuttings from the young shoots in spring and striking them under glass in a little heat, and by layering young shoots after ringing round each bud, so that each bud forms a plant. Of Moutans some of the best varieties are alba grandiflora, atro-purpurea, carnea plena, lactea, lilacina ocellata, papaveracea, and the white and red double forms; purpurea, Robert Fortune, Rollissoni, Rosa Mundi, Triomphe de Gand, Triomphe de Malines, versicolor plena, violacea purpurea, and Zenobia.

Soil and Propagation.—Pæonies grow best in light sandy loam, and need but little attention, digging round and manuring in the winter, and some care in tying them up neatly in spring being all they require. They may be readily increased, but it is most injurious to divide the roots too often, as in that case the constitution of the plants is weakened, and they generally take some time to recover their usual vigour; nor should they be dug up and removed too frequently, as this checks their growth for a season at least. R.

Lifting and Storing Dahlia Roots.—There are many different ways of storing Dahlias. The best I know of is to select a thoroughly dry day for lifting the roots and then to carefully cut the top off about 1½ in. or at the most 2 in. from the ground, the very best instrument wherewith to effect this being a sharp pruning knife. The roots should then be laid on any old stages that may be useless in the houses, or, failing these, on a few boughs, which, if placed so that the air can pass freely between them, would answer the purpose equally well. A pointed stick may be used to pick out the soil from between the roots, which the operator must be careful not to injure. Rather than run the risk of this it is better to let a small portion of the soil adhere to them. If the weather is fine the roots might lay out-of-doors for two or three days, care being taken to cover them at night; but if rain appears likely to fall, it would be best to take them into a shed or inside of a Vinery, on the border, at the back or under the stage of which they are not noticeable, and where the ventilation that is required to keep the other things healthy in the house will also prevent the Dahlia roots from damping. In case of a new variety or one that is weak it would be advisable to lift and pot it, placing it in a dry place with the others. Different growers have different methods of storing, such, for example, as laying the roots in a shed, and covering them with straw, ashes, and sand. In some instances each variety is tied up separately in old pieces of fish netting or matting, and suspended to the walls or roof of a warm shed. By such drying modes of storing, the tubers become very shrivelled and are much injured, but in the method I have described the only objection is the somewhat untidy appearance that it gives to the house.—H. G. W.

Primula cortusoides amœna.—All who have a fondness for beautiful spring flowers and have not this Primula and its parti-coloured congeners should at once secure plants, as they are now at rest, and can be easily sent by post in a very small space if shaken out free from soil. Those who have plants will find this to be the most suitable time to propagate them or to repot up either into small pots singly or in large pots in quantity, as desired. When the old plants are shaken out it will be found that a number of crowns are developed, each one having a portion of root attached. If each one be potted up singly into small pots they will

make strong plants in the spring, but in order to produce a good head of bloom, it is best to put several crowns into an 8-in. pot in good fine soil, enough of which should be placed over the crowns to almost cover them. Early in the spring these will push growth, and soon a perfect head of remarkably handsome foliage is produced. The flowers are well thrown up, and, whatever their hue of colour, make a very pleasing pot plant—indeed, I believe this family of Primulas to be one of the most beautiful of the whole genus. Primula cortusoides amœna, because of the rich hue of colour and the stiff erect flowers, produces a most effective mass of colour in the spring garden. For bedding, plants should be turned out of pots early in spring after good growth has been made, as they cannot then be injured by frost. In addition to amœna, lilacina is a very fine lavender-coloured form, grandiflora alba has large pure white flowers, and grandiflora rosea has very large flowers that are white above and red below.—B. D. F.

Belladonna Lilies.—Eight or ten years ago I purchased a number of bulbs of this really handsome Lily at St. Saviour's, Jersey, a portion of which were potted in the same way as Lilium japonicum would be ; the rest were planted in one row 6 in. deep, in rich soil, and 6 in. apart, close to the south wall of a hothouse. Those in pots I could not induce to bloom, probably from neglecting to water them when they were growing, but the bulbs that were planted near the wall made some progress the following year, and produced a few blooms. As they gathered strength, the bulbs, and, consequently, the blooms, increased in size, and are now a fine sight. In a few weeks they will begin to make new growth, and this must be protected from frost by a thin board reared against the wall. In spring the foliage will grow rapidly and attain a height of 15 in. or 18 in., finally ripening and dying by the end of the summer. During May and June occasionally soak them with liquid manure. We all know, or ought to know, that except strong, healthy, and well-matured foliage is produced, it is in vain to look for satisfactory flowers or fruit. The present is the best time to plant these Lilies, and they may be purchased from all seedsmen who sell collections of bulbs. I am informed the supply is somewhat limited ; therefore I should advise all who care to attempt their cultivation to make their purchases at once. The bulbs must remain where planted for many years if a fine display of bloom is desired.—R. S. Y.

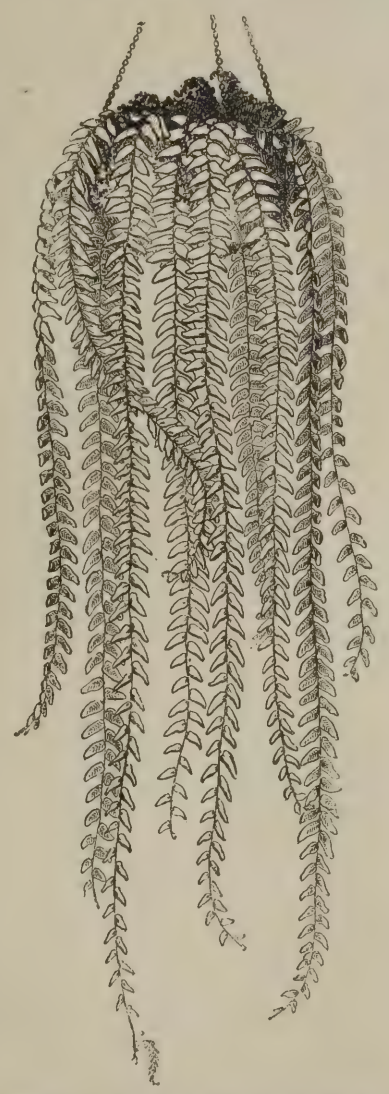
The Best White Edging Plant.—If I were asked to name the most useful, and at the same time most lovely, of the dwarf white edging plants now in use, I should say Achillea umbellata. It is perfectly hardy and certainly requires less manipulation than the dwarf Cerastium tomentosum. The latter requires renewing every year, whereas the former will be as effective the second and third year as the first. For carpet bedding it is a gem in every way, and only requires to be known to be appreciated. It is easily increased by cuttings taken off in September or October and dibbled in very thickly under a wall. We have thousands planted under the foot of a west wall, and they give no more trouble than this—after a severe frost in spring to sprinkle a little sifted leaf-mould over the cuttings, and with the hand press into the soil those that have been forced out by the frost. The few leaves falling from the fruit trees give sufficient covering now until rooted, after which they will take care of themselves.—C.

Tulips.—If the soil is in good condition these should be planted at once. It is always best to have some good fibrous loam under cover to place on the surface of the beds ; this should be free from manure, but the soil should be rather rich underneath. An old author says, "The Tulip asketh a rich soil and the careful hand of the gardener." When the beds are ready begin to plant at once, making a hole with a small trowel, and putting in a little fine dry sand, then the bulb, and over it a little more sand ; then cover all with loam to the depth of 2 in.

Hardy Lady's Slipper.—These are now, to all appearance, at rest, but on examination it will be found that the roots are growing, and that the stem for next season is in an incipient state. Now is the time to re-pot them. Shake all the soil from the roots, fill clean pots half-full of potsherds, and then repot in equal portions of fibrous loam and fibrous peat, mixing some bits of charcoal amongst it. Plant a little Sphagnum on the surface, and if this is just kept in a growing state during winter that will afford sufficient moisture.

Phloxes, Delphiniums, Pyrethrums, &c.—These have now assumed the sere and yellow leaf. The stems must all be cut over close to the ground. Stir the surface soil well up, and keep the beds and borders free from weeds.

Basket Ferns.—The genus Asplenium contains many beautiful species, and, being found in all parts of the world where Ferns grow, they are adapted for the hardy, temperate, and tropical Fernery. Some, from their trailing habit, make desirable basket plants, as will be seen by a glance at the accompanying illustration of A. longissimum, an elegant species with



Greenhouse Basket Fern (Asplenium longissimum).

fronds measuring from 3 ft. to 6 ft. and sometimes 9 ft. in length. Its bright ebony rachises and olive-green shining pinnæ also add greatly to its beauty. It is a native of the Indian Archipelago, and was introduced into this country some years ago by Messrs. Veitch & Son, of Chelsea. The most suitable baskets for it are plain hemispherical wire ones, well painted, and the soil should consist of three parts turfy peat, one part loam, and one part sand. Before inserting the plants the sides of the baskets should be lined with a layer of peat, and a few large potsherds should be placed at the bottom for drainage—an important point even in the case of baskets. The spaces between the roots and the sides of the baskets should be made up of the above compost mixed with pieces of charcoal or potsherds, in order to allow the air to permeate the soil. A few rooted cuttings of Ficus minima or F. stipulata would, if inserted in the sides and pegged down, hide the soil from view. Panicum variegatum, Tradescantia zebrina, Selaginella Kraussiana, S. uncinata, and S. Galeotti would answer the same purpose, and are, moreover, themselves attractive. The spores (seeds) of A. longissimum rarely germinate, but it can be propagated freely from the bulblets, which are produced at the end of almost every frond ; these grow rapidly, and in about three years make fine specimens. Several allied species are also adapted for basket culture, such as the graceful A. furcatum, which grows plentifully on trees in the warmer parts of both the Old and New World, and which has a very ornamental appearance ; A. flaccidum, a fine species with deeply-cut, drooping fronds of a succulent character, also makes a good basket plant, as does likewise A. nitens, though smaller than the preceding ; A. rhizophorum and its numerous varieties make desirable specimens, especially the variety called rachirhizon, the fronds of which taper into long whip-like appendages, the whole frond reaching some 2 ft. in length. A. lineatum, a native of Mauritius, with fronds from 2 ft. to 3 ft. long, cut into numerous linear segments, makes an excellent cool conservatory plant.

Preparing for Spring.—The chief interest attached to spring gardening is the fact that it seems to open up to us a new floral world. What an infinitude of material it brings to the surface ! Double Daisies, single and double Primroses, Polyanthuses, Violas, and Pansies ; Arabis, Aubrietias, Alyssums, hardy Primulas, Saxifrages, Wallflowers, perennial Cheiranthus, Iberis, Anemones, Myosotis, Sedums, hardy annuals of kinds, and innumerable plants, all of which, if cultivated and properly grown for the purpose, will produce masses of colour and charming effects. To the lover of spring flower gardening how welcome is the time when the tender exotics of the summer bedding are sent into their winter quarters, and the beds are ready for winter planting ! What an additional pleasure does this labour bring in the knowledge that, whilst in gardens where there are no spring flowers the beds will be flowerless for the next seven months, in those where spring flower gardening is carried out not only will the beds be full all the year round, but the blooming period will begin in March, and thus add three months to the ordinary floral season. The late rains have not only got the soil into capital order for planting, but all sorts of spring flowers are pushing up strongly, so that the work of separating and increasing the stock may begin at once. The Primrose is the queen of spring flowers—a universal favourite with all, and the new, richly coloured forms are like so many gems set in a green groundwork. Pansies and Violas will also need immediate attention, as these will admit of being pulled to pieces, and will furnish plenty of well-rooted plants. These, put out in rich soil, will flower early, and produce masses of gay colours. Daisies also now require the same treatment, for no spring flower garden is perfect without a sprinkling of these "wee modest flowers," the variegated kinds especially being very striking all through the dull winter months. Spring flower gardening is not essentially of the "bedding" order ; on the contrary, it may be done in any fashion, just as may best suit the taste of the operator ; but spring flowers are essential to the perfect enjoyment of any good garden, and it is only those who have become familiar with them that can fully realise the inestimable pleasure which they afford Where spring flowers are not used, and it is desirable to give flower beds a cheerful appearance during the winter months, they should now be filled with various hardy plants which have been kept in store for that purpose.

Mignonette for Cutting Now.—It is a good plan to sow Mignonette seed in some out-of-the-way spot during the month of June, as it germinates speedily after the first shower, and grows into strong flowering plants by the end of September. If the spot be slightly sheltered by trees the plants will not be affected by the earlier frosts, and as a considerable interval often elapses between these and severe winter weather it is easy to secure an abundant supply of sprigs of this fragrant flower long after other tender plants are over. There is no finer and more useful Mignonette than Parson's Giant white variety, as it grows rapidly, and has long neat branches and flowers that are whiter than those of any other kind. From self-sown plants of this kind I can now cut, at any moment, handfuls of sprigs that are most acceptable at this period of the year.—D.

Cutting Down Herbaceous Plants.—I think some hints as to the ways of protecting choice half hardy and Alpine plants would be useful at this time. I do not think it is the frost which kills the plants, but the alternations of wet and dry. At p. 404 it is stated, "Cut Phloxes and Larkspurs over close to the ground." I think it better to leave the stems of my herbaceous plants 5 in. or 6 in. high, as they are a great protection from frost.—E. A. H.

Lilium auratum.—A friend of mine this year purchased a 1s. 6d. bulb which was placed in the open ground, the soil being sandy and the situation as much exposed as possible. The result was a magnificent spike of bloom, on which I counted thirty-three flowers, all of large size. I should, perhaps, state that the stem was abnormal, *i.e.*, flat, like Asparagus heads occasionally grow. This may account for the large number of blooms.—W. E. G.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

November 15.—Cleaning among herbaceous plants; potting Ghent Azaleas for forcing; shifting large herbaceous Calceolarias in 24-in. pots; re-boxing Ivy; putting cuttings from cold and damp pits on shelves in Vinery; planting out Guernsey Lilies under a warm wall, also Roses, manuring them and giving some of them fresh soil; planting Horseradish; putting some Cinerarias into slight heat, also Seakale, Asparagus, and Rhubarb; filling up empty frames with Lettuce from under wall; taking up more Schizostylis and Narcissi, also more Cauliflower; nailing wall Plum trees; putting Roses (Tea-scented sorts) into a cool Vinery; getting all Violets in pots into frames; covering up Globe Artichokes with straw; protecting seed Potatoes; laying all fresh potted Roses out-of-doors on their sides and plunging them in straw.

Nov. 16.—Digging flower borders; planting Fig and Peach trees, Raspberry canes, also Anemones, giving the latter manure and sand; putting in Hyacinths, Tulips, Dielytra, and Lily of the Valley to force; finishing all north-wall nailing; making a new Mushroom bed.

Nov. 17.—Potting some Azalea pontica; making a pit ready for forcing flowers, keeping it at 65° at night and 70° by day, slightly syringing when necessary; nailing Apple and Pear trees; putting hand-lights over Cauliflowers; looking over bedding Pelargoniums and cleaning them; all Vines pruned now except late ones; shortening Rose shoots a little in order to keep wind from rocking the plants; running dirty water out of boilers.

Nov. 18.—Sowing Mustard and Cress regularly; layering some Cucumber shoots in pots for early spring work; finishing planting old bulbs out-of-doors; planting out February Cucumber plants; put in some Indian Azaleas to force for flowering by December 30; taking the Roman Hyacinths in flower out of heat; syringing Gardenias with soap-suds once a fortnight; watering Asparagus just appearing; also top-dressing Oranges and giving them some Standen's manure; stirring the soil amongst frame Violets.

Nov. 19.—Potting Lilies in peat and sand, and plunging them out-of-doors overhead in sand; planting out Sweet Williams and Wallflowers, taking them up with large balls, also climbing Devoniensis Roses in conservatory; taking up some Anne Boleyn and White Pinks for forcing and potting them; spreading out seed Potatoes in cellar to keep them from sprouting; giving Gardenias a top-dressing of turfy loam and Oak leaves; earthing up winter Cucumbers weekly, ½ in. at a time; pruning all Roses for forcing.

Nov. 20.—Digging borders and manuring highly for Roses; putting in second Seakale to force; wiring Wallflower beds to keep off rabbits; Neapolitan Violet border manured and fresh soiled with rich material; examining Grapes and cutting out decaying berries; freeing cuttings from dead leaves.

Flower Garden.

Presuming that the flower beds have been filled, either with material for winter effect, or with spring-flowering plants and bulbs, there will now be little else to do in the flower garden except the maintenance of neatness, which is a matter more than ever desirable at this dullest of all seasons of the year. In other portions of ornamental grounds, which are generally designated flower gardens, there may still be found abundant work, such as thinning out clumps of shrubs, or planting additional ones or single specimens, of either deciduous trees or evergreens. Any tree or shrub may at this season be moved with safety. Of late years there has been such a demand for Coniferous plants, and particularly within the last two or three years, for the Japanese kinds, that deciduous trees have become neglected; and, granted that this class of plants is interesting and beautiful, still, at the present rate of planting them, combined with a proportionate neglect of deciduous trees, ornamental grounds a few years hence will present more the appearance of cemeteries than that of pleasure grounds. To prevent this in all new planting there should be a judicious admixture of the finer deciduous trees, such as Acacias, Maples, Thorns, Turkey Oaks, Tulip trees, Liquidambars, Purple Beeches, Lombardy Poplars, Spanish and Horse Chestnuts, &c. In forming clumps of shrubs also evergreens are often too prominent, whilst flowering deciduous shrubs, such as Lilacs, Deutzias, Snowberries, Spiræas, and Weigelas, which are in every way suited for association with the dwarfer-growing evergreens, are neglected. Half-hardy plants that are to winter in the open air should now receive partial protection by surrounding the base of the plants with ashes, Cocoa-fibre, or bracken, and some of the choicer Ferns and rock plants will require the same attention. Dahlias, Gladioli, Tigridias, and Marvel of Peru should all now be dug up and dried previous to finally storing them away. The ground is so full of moisture that it will scarcely be safe to leave Cannas out for the winter, as a sodden state of the ground is more fatal to them than severe frost. If lifted the roots will winter safely in any place from which frost can be excluded. This is the most critical time for the well-being of bedding plants; damp is their great foe, and therefore water but sparingly, and keep the hardier kinds well exposed to induce sturdiness. Tender kinds, such as Coleuses and Alternantheras, will not winter successfully in a lower temperature than 65°, and they must be kept well up to the light.

Auriculas.—Remove from beds of alpine Auriculas out-of-doors all decaying leaves, and destroy weeds before they grow to a large size. The surface of the beds should be loosened either with a small hoe or a pointed stick. Slugs are very fond of the leaves, and perhaps the best way in which to destroy them is to pick them off at night. For out-of-doors culture seedlings are better adapted than choice named sorts. A packet of seeds costing about half-a-crown would produce as many plants as would plant a large bed. It is not the time to give precise instructions as to sowing the seeds, as March is a good month for that operation; they are, however, easily raised, and the plants can be grown on to a flowering size with but little expense or trouble. Alpine and show Auriculas thrive well on sheltered banks, planted amongst lumps of stone or clinkers, in such a position that it is not possible that water can lodge about the collars of the plants. However much these fine plants may be valued for frame culture, it is even more desirable that they should be introduced wherever practicable as hardy occupants of the flower garden.

Carnations and Picotees.—Near London growers do not think of planting choice varieties of Carnations and Picotees out-of-doors to stand over the winter, and yet so far north as Newcastle-upon-Tyne this is done successfully; growers there will now be making arrangements to plant. If the plants are put out in the spring such good flowers are not obtained. When the plants are put out a small stick is placed to each, in order to prevent the wind from snapping them over, and the surface of the beds has to be covered with some dry, rotten stable manure. This mulching prevents the plants from being thrown out of the ground by frost, and also further helps to steady them. Damp is one of the worst enemies with which the Carnation has to contend; even intense frost is not so injurious.

Hollyhocks.—If the choice varieties have not yet been taken up, this ought to be done at once, and no time should be lost in potting them. The roots should be cut back considerably, and all old leaves removed, in order to allow the young growths at the base of the stems to develop themselves. Do not overpot nor squeeze the roots into a pot not large enough to contain them, although that is better than over-potting. See that the young plants are kept free from red spider and other pests. If the plants have been put out in a cold frame the leaves will continue to decay in damp, foggy weather; let them be removed at once to prevent further injury. Some take off the cuttings from the base of the stem now, but this is only to be recommended if there be so many that they would injure each other during the winter. January, February, and March are the best months in which to propagate for late flowering plants. See that the frames are freely aired, removing the lights as often as possible with safety.

Pansies and Pinks in Beds.—Any plants that seem as if they would not form free-flowering healthy specimens should be removed, and others taken from the reserve stock to fill up their places. It is necessary that this should be done in the case of scarce sorts that are weakly. They should be taken out and be repotted in small pots, or they may be lost altogether. Pinks may be treated in the same way. A pair of plants should be wintered in a 3-in. pot, and treated in the same manner as Carnations and Picotees. If there are any vacancies in the beds of Pinks they must also be filled up from the reserve stock in pots kept for this purpose.

Forcing Pinks.—These are now, or ought to be, well established in their pots. Go carefully over the plants and remove all dead and decaying leaves. Stir the surface of the soil, and press down the plants gently by placing the fingers near the stems. Give plenty of air at night as well as by day, unless there is danger of frost.

Glasshouses.

All the remaining stock of Gloriosas, summer-flowering Gesneras, Gloxinias, Achimenes, Caladiums, &c., will now require to be put to rest, but avoid the common error of keeping them too cold, or placing them under stages near pipes that are sometimes too hot and at other times the opposite. In such places the soil frequently gets wet with the water that runs from plants on the stages above, and, if severe weather comes, necessitating the use of considerable fire-heat, the roots get too much dried up. While at rest, the temperature of an intermediate house will suit them best, but where room in this way cannot be afforded, so as to allow their remaining in the pots in which they have been grown, let them be taken out and put in dry sand in boxes or paper bags.

Allamandas.—Where plants of these exist grown on the roof, either planted out or in pots, the time of putting them to rest will be dependent upon the purpose they are required for; if not needed in bloom until late in the spring they may still be kept on blooming, and at no season will their flowers be more useful than for some time yet, as when not exposed to an unusually cool dry atmosphere they last longer in a cut state through the winter than during the spring and summer; and where the house in which they are grown affords heat enough to keep them flowering up to the end of the year, and even beyond this, all that is necessary is to give as much water to the roots as required; but where they are wanted to bloom early, and consequently to be cut back about the beginning of the year, it will be better to now subject them to a drying process at the roots that will stop all further growth.

Æschynanthuses.—Where these are grown hung up in baskets and pots in the way they are seen to the best advantage, the soil should be kept as dry as can be done without causing their leaves to shrivel, which will permit of the shoots being now shortened back so far as deemed needful previous to their again commencing growth. The advantage gained by so treating these plants and others of like character that are hung up from the roof is that by the reduction in their heads they intercept less light from the main occupants of ths house.

Hoyas.—The drooping kinds, such as H. bella and H. Paxtoni, so useful for suspending like the Æschynanthus, if their shoots are not well shortened back each year, get into a long, straggling condition, and cutting them in now, as advised with the last-named plants, will answer equally well to deferring it until spring, providing corresponding care is taken to give them no more water than requisite; and when their heads are thus reduced there is a better chance of cleaning them from scale, bugs, or any similar insects with which they may be affected.

Gardenias.—Plants of these required for winter flowering should have the best position that the warmest end of the stove can afford. They are, more than many things, liable to drop their bloom-buds in the winter season, often when so far advanced as to be almost on the verge of expanding; extremes from any cause, either of being too dry or too wet at the roots, too much moisture in the atmosphere, too much heat suddenly applied, or the opposite of being too cold, especially after the

flowers have attained considerable size, will cause their falling off, although the mischief will not always be apparent for some weeks after, whatever may bring it about has occurred. The most effectual means for avoiding the flowers dropping is to keep the plants in as light a position as possible. The little G. citriodora, blooming as it does in such a small state, if grown in quantity will always be found useful, especially where many flowers are wanted for bouquets.

Amaryllises that bloomed late, and made correspondingly late growth, will now need keeping at rest. This refers both to the deciduous and evergreen kinds; the former are safe anywhere with the heat of an ordinary greenhouse, and will bear the soil keeping quite dry. The evergreen sorts should be kept sufficiently dry during the winter to get them fairly to rest; but, on the other hand, they must not be let to become so dry as to cause their leaves to shrivel, as where this happens premature loss of foliage is sure to occur, which reduces the strength of the bulbs. With young stock of the evergreen species the roots should not be further dried than will result from keeping the soil in a slightly moist condition.

Tuberoses.—There are few things that afford such a long succession of flowers as Tuberoses, for where enough are grown they may be had in bloom for much the greater portion of the year. Those who want to have them in good time should at once provide a sufficient quantity of roots, potting a portion up without delay, and keeping the remainder dry for the present, potting them at intervals. The American grown roots are held in much the most favour at the present day. Those who have had little experience with these plants often fail in getting the bulbs to start, generally through their decaying instead of forming roots, and to which they are very liable unless great caution is used in the matter of water; for if the soil is kept in anything approaching the moist condition that most other plants would need the mischief is almost certain to occur. We have succeeded best by potting them in soil in a comparatively dry state, and then standing the pots on the earthen floor of a pit, or some moisture-holding material slightly damp, from which the pots will usually absorb enough until the roots are well in motion, when they will bear the soil to be kept fairly moist.

Planting Fruit Trees.—The necessity for early planting and renovation of fruit tree borders has been so often insisted on in these pages, that nothing further need be added except that such work should, if possible, be brought to a close by the end of this month. Any that then remain to be done had better be deferred till vegetation again becomes active. From the foregoing it will be seen that we attach some importance to the season, or what may be termed the right time for planting; but after all, comparatively speaking, this is but a secondary consideration, as successful planting may be done any time from October to April; but we attach the greatest importance to the mode of planting; by which is meant not only the literal planting of the trees, but the proper preparation of the ground for them, and in doing this the first essential is good drainage. Every kind of cultivated hardy fruit, from a Peach to a Gooseberry, resents anything like a stagnant state of the soil; moreover, good drainage increases by several degrees its temperature, and, as a matter of course, this must aid the more perfect development of the fruit. The kind of soil that suits fruit trees generally is a calcareous loam of moderate texture—that is neither heavy nor light—but of necessity this matter must be subject to local considerations, as often the soil best suited for certain trees is not obtainable; but, though there is a best kind, they are by no means fastidious, and all soils worthy of the name can by a little outlay of time and money be made to grow fruit well. Light ground should be trenched very deeply, and, if procurable, heavy loam or clay should be intermixed with it, but if this be not obtainable, well firming will in some measure atone for its absence. Very heavy or clayey soils should also be trenched, and any sort of material that would render it more porous, such as mortar rubble, charcoal, and cinder ashes should be added, and it must be allowed to subside naturally, without artificial compression. Unless the soil be very poor indeed, no manure of any kind should be mixed directly with it, for the simple reason that the disposition of all fruit trees, when planted in rich soils, inclines towards the production of wood rather than fruit. It must not be inferred from this that manure is not essential to the production of good fruit, for it most certainly is, but never till the trees have fairly begun fruiting, and then annual surface dressings have the most marked effect, for thus applied, it is not only valuable from a fertilising point of view, but it tends to keep the roots near the surface, a position in which they are most benefited by the action of sun and air. All who have plenty of ground for kitchen garden crops should never think of encroaching on the fruit tree borders, and those who by the force of circumstances must thus crop, should at least allow each tree a fair modicum of space. Keep the roots near the surface; deep planting is an error. Above all, let them be well spread out, and the soil worked well amongst them with the hand, and afterwards let the trees be securely staked, for till that is done all fresh roots that may be made will, by the first gale, be destroyed through the swaying to and fro of the tree.

Vegetables.

Celery.—The last crop of Celery should only be about half-earthed up—that is, the ridge ought not to be brought higher than the centre leaves, leaving those exposed to the light until later on, to protect which sufficient material should be in readiness, in the shape of stable litter, dried Pea haulm, dried leaves, or, best of all, Fern. Where possible, secure a good supply of this useful material, which for all purposes of protection from frost is superior to all others. It must, however, be kept under cover, for if it is allowed to lie in masses and get wet, it will rot. It is now dead and in right order for gathering. A dry day may be chosen for cutting it, and it may be stowed until required under a temporary covering of any kind, or placed a couple of yards thick over Potatoes, Carrots, or Beet in the root-shed, and here kept until wanted. Not only is this Fern (the common Bracken) good for the purposes mentioned, but it is also invaluable for laying over beds of Hyacinths, or for placing round crowns of tender herbaceous plants, the collars of Tea Roses on their own roots, or for putting around the heads of standard Teas. It may be added that there is nothing objectionable or untidy in its appearance when thus used.

Potatoes.—It will be well to again turn over the crop of Potatoes and remove any diseased ones that may have escaped detection previously, as, if allowed to remain, they affect all they come in contact with. Even if there is a total absence of disease they are very much improved by turning over in this way if at all damp. To have Potatoes in the best condition they should be quite dry for a considerable time before using.

TOWN GARDENING.

RAISING PLANTS FROM SEED.

In the first place, as we have before urged, always buy the very best seeds, and get them from a well-known house or dealer. Cheap seeds generally turn out to be very dear. Also, when you buy plants or cuttings, get the best named kinds if you can, and pay a good price to a good man or house for a good thing. There is no need, as a rule, to buy a quantity, unless you want a great display at once, and can afford to pay for it. The best way is to get one or two plants of a good variety, and propagate from them yourself; this is much better than buying a lot of cheap rubbish. There is nothing over which an inexperienced person is so likely to be taken in as plants, unless you go to a really respectable place that has a reputation to keep up. Get your seeds in good time, and do not have it all hurry and careless work at the last. Remember that though spring does not come so early in town as country, yet things take longer to grow to a good size and get strong.

Time to Sow Garden Seeds.—Hardy annuals out-of-doors, end of March or April, and if a succession is required, at intervals up to the middle of June. Half hardy annuals, end of April or May out-of-doors. Greenhouse seeds for winter blooming (Primulas, &c.), in March under glass. Greenhouse or garden annuals, half hardy or tender, from April 1 to the end of May.

Soil.—For seed sowing out-of-doors, the soil should be rich and fine on the surface. Most things (annuals, &c.) are sown where they are to grow, and as such are rapid growers, the soil beneath can scarcely be too deep or rich. It should have been recently dug two or three spades deep, working in a quantity of rich, rotten manure especially deep down, and should not be trodden down or made hard, but just left for a few weeks to settle. Of course everyone knows that all digging and working should be done when the ground is dry; during frosty weather is the best. If in a border where there are shrubs or other things, and the ground has not, from this or other cause, been trenched previously, dig in some manure as deep as you can in the patches where the seeds are to go a few days beforehand. If not well settled, pat it down gently with the back of the spade, and rake the surface fine and level, picking out all stones, clods, or lumps, and giving a good watering if very dry. Have a basketful of rather fine sandy soil, such as the refuse from the potting bench, in a nice dry state, and a little fresh leaf-mould mixed with it if at all poor or spent. This should, however, not be too fine, or it is apt to become pasty when wet. Spread a little of this over the patch, and pat down gently with the back of the trowel.

Sowing and Thinning.—Sow the seed not too thickly, say six or eight seeds of large things, or twenty or thirty or more of small ones, and cover again with a sprinkling of the fine soil, but do not bury deeply, especially small seeds. If the weather keeps very dry, water gently with a fine-rosed pot to assist germination. When the seedlings appear thin them out if too thick, as by this means the rest grow stronger and flower finer. The thinnings of some may be transplanted if desired, as Tropæolums, &c., but Linums, Eschscholtzias, Mignonette, and some others do not like or cannot bear being moved. It is astonishing what a splendid display annuals will make if they are well grown, that is, in a deeply stirred, light, and rich soil, into which they can root readily, deeply, and strongly, and if they are properly looked after, weeded, thinned, and watered, when the weather is dry.

Seed Beds.—Many annuals, especially those that are not quite hardy, also perennials and biennials, are sown out-of-doors in what are termed "nursery beds." These may be made in any warm, airy, and light corner. They are better to be somewhat raised above the general ground level, and if a framework can be arranged over them and round, so as to protect them from heavy rains and cutting winds, they will be more successful. Have plenty of broken bricks for drainage at the bottom, or if the seeds are tender and want a little heat, and if you have no frame, it is well to make a heap of manure or spent Hops, and put the soil 3 in. or 4 in. deep upon that. If there is no fermenting material beneath, however, it will be better to have a greater depth than this, say 4 in. or 6 in. of rough and rich soil over the drainage, and 3 in. or 4 in. of nice fine sifted soil on the top, about equal parts of loam, manure, leaf-mould, and sand, or rather less of the latter, is about the best; this will do just as it is for pricking out young plants, but if for sowing seeds, have about 1 in. of fine, light, sandy soil sifted, such as leaf-mould and sand, on the surface. On such a bed as this, with a gentle bottom-heat, all such things as Stocks, Asters, Phloxes, Indian Pinks, &c., will come up easily, but they would be better under glass. These nursery beds, without the bottom-heat, will do well for planting out Stocks, Asters, and many other things to strengthen from the seed-pans say about the first week in May. From here they are planted out into the borders about the end of the month.

Sowing Under Glass.—Although it is much better to sow all but hardy annuals in frames, &c., yet many gardeners even in the country, where not nearly such care is requisite, are far too fond of coddling things and forcing them on in heat. Mimulus, for instance, one is nearly always told to grow in heat; now these pretty little plants are all but hardy, and the seed should be sown either in autumn (September), and pricked off into store pots or boxes, and kept in the greenhouse till spring, or sown in a moderately warm greenhouse or frame (45° to 50° in

quite enough) in January or February, be pricked out into a cold frame at the end of March or early in April, and by this means you will have such plants and flowers as no grower in heat can produce. Lobelias should be treated exactly the same, and not be left till April, and then have to be pushed on fast, with the result of weak and lanky plants and poor flowers. Phlox Drummondi, too, and Indian and Chinese Pinks, Asters, Zinnias, with many others, are far better raised in only a gentle heat (60° is plenty), or even none at all, than run up and spoiled in a Cucumber or other hot frame, as is so often done. Calceolarias (herbaceous) and Cinerarias, too, should never be raised in heat, as many direct; in fact, these plants shou'd never have more heat at any time than just enough to keep frost away, excepting, of course, where Cinerarias are wanted to bloom in winter.

In sowing seeds, especially in early spring, always use plenty of drainage (broken crocks or bricks) in your pots or boxes, or you will find your little plants "go off" at the surface of the soil almost as soon as they are up. When using pots we fill them nearly half full, and for boxes from 1 in. to 1½ in. is enough, if there are plenty of holes bored in the bottom as well. Over the drainage put a thin layer of spent Hops, Moss, or fibrous matter of some kind to prevent the soil from washing down and clogging the drainage. Then put about 1 in. or 1½ in. of soil, not sifted, and if the seeds are small, another thinner layer of very fine sifted soil above that, so that the whole may reach up to within ¾ in. or 1 in. of the top of the pot or box. We use boxes about 3 in. deep inside, though they may be a little more if preferred, and any size up to 8 in. or 9 in. wide, and 16 in. or 18 in. long is suitable.

Watering Seeds.—Watering at first is a most delicate and important point. What is to be aimed at is to have the soil just moist enough not to require any watering till the seeds are well up, as it is very undesirable to do this, and yet it must not be anything like wet, or many seeds are apt to rot and never come up. The best plan is to use the soil almost dry, or only barely moist, but not dust dry; put in the drainage and about half the depth of soil required, press it down firmly, and give it a good watering; if it is in a pot soak it half-way up in water, then fill in the rest of the soil, pressing the upper portion only slightly. Make the surface even and level; use no more water, but sow the seed at once, and cover with only a dusting of dry soil. Place a square of glass over the pot or box, and the job is done. By this means you get enough moisture in the soil to last for days without the surface being wet; the moisture is sure to rise quite sufficiently, and the water being down below induces the seeds to send down roots to find it. You get also a firm bottom, which holds moisture, and is of great importance, and a free, light, uncaked surface, in which the seeds will rapidly germinate, and into which the first tender rootlets can readily penetrate. As soon as ever the seeds are up tilt the glass a little on one side, or remove it altogether for an hour morning and evening. Give more and more air as they advance, and remove the glass altogether as soon as they can bear it. Also bear in mind that damping off occurs as often from too much dryness at the root as from excessive moisture overhead. When you see a pot or box of seedlings beginning to go off, examine the soil, and if dry give a thorough soaking, not a mere sprinkling. It has often been said before, but cannot be repeated too often, and applies especially here: never water plants (particularly tender seedlings) in driblets, whether they want it or not, but wait till the soil is dry, though not necessarily till the plants flag, and then give a full supply, enough to reach every fibre of the roots; after that wait till wanted again. When pots are very dry, and particularly in the case of pots or pans of very small seedlings, such as Lobelias, Calceolarias, or Tuberous Begonias, only just come up, it is better not to water from the top, as the water will often run away without wetting the soil, but plunge the pot or pan in water up to about half-an-inch or an inch below the level of the soil, and let it stay there till the soil is thoroughly moistened. In this way the soil gets well watered, as well as the roots, while the stems and leaves are kept dry, which is just what is wanted. In watering things from a hotbed in any way use water of about the temperature of the frame, a few degrees over rather than under. We always use water with the chill taken off for delicate young things, even from cold quarters, for fear of checks.

For nearly all seeds, a sheet of clean glass placed over the pot or box after sowing is a great help, as it prevents evaporation and creates that close, moist atmosphere inside the box so favourable for germination. If the seeds are such as require heat, place in a hotbed or warm house of the requisite temperature, but be sure and not use more heat than is really necessary; 70° or 75° at the outside is enough for anything, except perhaps such things as Cannas and a few others, but for most things, even Begonias, Gloxinias, &c., we find that from 65° to 70° suits them much better than a higher temperature. More heat than is necessary only brings the plants up weak and sickly, so that many perish in hardening off. Petunias, Lobelias, Balsams, and all half-hardy or tender things of like nature only need from 60° to 65°, or even 5° less rather than more, in which to germinate; even the temperature of a greenhouse is sufficient, though the seeds are slow in coming up. Beware of keeping the sheet of glass on the box too long, or of coddling or keeping too close in any way, or the seedlings soon get so delicate and drawn, that many of them will damp off.

Maranta as a Vase Plant.

After sowing, seeds may be put in a dark place, or any odd corner, so that the temperature is right and there is no mildew or fustiness about; in fact, seeds germinate better in the dark; but as soon as ever they are up they must be brought close to the glass, the closer the better, so that they are not near enough to be touched by a frost or low temperature outside; so keep 3 in. or 4 in. away for fear of injury. It is always safer to cover up all frames, &c., that contain such tender things with mats, &c., on all frosty or cold nights, especially in the spring; this plan saves heat and has many advantages, but do not cover up till it gets dark, and be up and remove again betimes in the morning as soon as it is light, as young things want all the light they can get, especially when in a warm temperature.

Regarding the soil most suitable for seed sowing in pots, it must always be fine, light, and moderately rich, though it should vary considerably for different subjects. Leaf-mould is the most useful of all soils for this purpose, as its nature induces seeds to germinate in it far more readily than in any other kind of soil. Plenty of sand should also always be used, especially near the surface; it insures porosity and prevents damping. For most seeds, especially fine or delicate ones, leaf-mould and sand in nearly equal parts, rather less of the latter, is best. The top ½ in. or ¼ in. should be finely sifted for small seeds, but for Verbenas, Balsams, and other large seeds do not sift at all; only pick out all lumps, sticks, &c. Use the soil rougher and richer below, and finer and sandier on the surface. A little loam may be used in the compost, especially below the surface for strong growing things, as Stocks, Asters, Pansies, Hollyhocks, and others; but as it is apt to make the soil cake, leave it out for delicate growers.

(To be continued.)

GLASSHOUSES & FRAMES.

Fine-leaved Vase Plants.—Amongst the foliage plants that decorate our plant houses, few are more deserving of admiration than Marantas; coming, as most of them do, from wet parts of tropical America, they require to be grown in a moist warm atmosphere, and consequently do not well bear removal to rooms or conservatories, except for a limited time. This is much to be regretted. The well known Maranta zebrina was for many years almost the only one amongst the ornamental-leaved section of the genus that was commonly found in hothouses; but of late years many very beautiful species have been introduced. Amongst them, M. Veitchi is probably the most striking, the leaves being purple underneath and deep green above, with yellow markings near the midrib. They succeed well in peat and charcoal, or good fibrous loam and leaf-mould, and in summer when placed in the room or conservatory they should be sponged frequently to keep them free from dust, and also to keep the leaves moist.

TREATMENT OF CAMELLIAS.

Nearly all Camellia plants, if in good health, will set more buds than they ought to be allowed to carry to perfection; in fact, if left on, they seldom do retain them all till they open; and not unfrequently overloading the plants leads ultimately to weakly growth and small flowers. Therefore, wherever the flower-buds have set thickly they should be thinned, leaving one, two, or three buds on each shoot, according to its length and strength. In but few cases should so many as three buds be left. One bud will be sufficient on all shoots not more than 5 in. or 6 in. long. A plant thickly studded with well-ripened shoots carrying one bud each will in the aggregate bear an enormous number of flowers.

Nowadays, in using Camellia flowers for bouquet making, there is no necessity to cut the branch on which the flower grows, or any portion of it. Simply cut the flower off where the calyx joins the branch, and mount it on wire, so as to form an artificial stalk. There is a special wire made for this purpose, which may be obtained from any of the principal London seedsmen. After a little practice anyone can mount flowers on wire, but Camellias require more delicacy of touch than other flowers, as they show any bruises so distinctly. Two pieces of wire are required for each flower, and they may vary in length according to the length of stalk required, but from 9 in. to 12 in. is generally sufficient. The flower is held carefully but firmly in the left hand, whilst the wires are thrust half-way through, at right angles to each other, with the right. The exact point at which the flowers should be pierced with the wires will vary with different-sized blossoms, but the object is to hold the flower together without the wire being seen. The ends of the wires are brought down under the flower, and one is wound a few times round the other, forming a very handy stalk, much better than the natural one for bouquet making. Should foliage be required, there will be no difficulty in attaching leaves to the base of the flower by means of the wires. Camellia blooms mounted in this way are usually more lasting than if cut with a piece of their own wood attached, as the petals are very apt to drop out of the calyx when taken into a warm room; but when properly wired, the petals are held in position by the wires. Besides, when cut with a piece of wood, it is very difficult to bring the flowers to a face to display them properly, as, unlike Roses, they do not grow straight up from the ends of the shoots; but with a wire stalk they may be made to face in any direction.

Camellias at all times require a good deal of water, but especially at this season, as not only have they a large amount of foliage to sup-

port, but there is the load of rapidly swelling buds. At no season are the roots in a greater state of activity, and if not well supplied with water something must be wrong; usually it is the buds that first give way when the period of trial comes. I have occasionally come across cases where both the buds and leaves were falling through want of water, and when buds or leaves begin to fall the roots should be examined, not only on the surface, but the bottom of the ball, or, if planted out, open the border and see what sort of condition the bottom is in. When a hard ball in a pot becomes thoroughly dry, the pot should be placed in a tub or tank till all the air bubbles have done rising, then lift it out and water with more care in future. At this season onwards for the next two months there is more danger of mischief being done by withholding water than at any other period of the year. Plants do not flag now as they do when the leaves are soft and a hot bright sun is shining, and especial care should now be given to plants growing in beds. Conservatories are often kept too warm in winter to suit the wants of Camellias, and if, in addition, they only receive a scanty supply of water, something must go wrong. A gentle dewing overhead in the morning of fine days will be beneficial, and the sponge should be used as often as possible, to keep every leaf bright and clean. Weak soft soap and water will give a gloss and polish to the plants that add much to their healthful appearance. Camellias, when well cared for, will live to a very old age, constantly increasing in value. I was in a conservatory in Worcestershire a short time since where there was a tree of the old double white that must have been much more than fifty years old. I knew it more than thirty years ago, and it was then a large old plant. It is still in robust health, and is carrying an immense number of blossom-buds.

There is no doubt that Camellias planted out in a lofty house, without much artificial heat, will grow to a much larger size than is generally supposed. Good turfy loam, where it can be had, should form the basis of all borders for Camellias, and everything in the shape of leaf-mould, unless thoroughly decomposed, should be rigidly excluded, as it is apt to engender fungus. I was visiting a large nursery establishment in the north some time ago, and the border of a large house, into which a great number of Camellias had been planted for cut flowers, had become so infested with fungus spores, and these had so affected the health of the plants, in spite of all that could be done, that they were at last compelled to lift the plants and pot them.

This, I know, is not an isolated case. I once had to deal with a similar one. I lifted the plants out and renewed the soil twice, and drenched both the plants and the borders frequently with soot water, until I ultimately conquered the fungus; and afterwards the plants grew amazingly, and produced very fine flowers. Although rough leaf-mould, or the bits of roots and other foreign matter frequently found in peat, will engender fungus under certain conditions, yet, if the border be kept moist, it will not make much headway. It is when the border or any part of it gets dry that the fungus spores vegetate and spread so disastrously; and when the fungus reaches that stage it is very difficult to drown it out, as water will not penetrate the dry spots so long as a passage can be found in any other direction. Hence the necessity for care in watering Camellias that are growing in beds or borders. Soot water in a weak solution may be given with advantage at this season at every watering. It will support the foliage, imparting to it a dark green colour; and a plant with firm, healthy foliage very rarely fails to produce good crops of flowers. H.

Isolepis gracilis as a Fringe to Large Pots.—This is a most useful plant for hanging over the rims of large pots in which Palms, Camellias, &c., are grown, and it should be cultivated in quantity for such purposes. Small plants of it in thumbs, or 3-in. pots, can be readily dibbled in over the surface of large pots, or planted so as to form a fringe hanging over their edges. A few plants, or even a row hanging down in front of the stages in greenhouses or conservatories, have a charming effect. Another method with this plant is to place it in small pots; under the rim of these pots is placed a stout wire, with a portion of it turned up to form a loop. In most old conservatories or on the back walls of old-fashioned plant houses where Camellias and various creepers are usually grown, there are almost sure to be bare naked places in which a nail driven here and there, and a pot of the Isolepis with its wire collar placed on them. will have a novel and refreshing appearance. Under such circumstances the plants will soon hide the pots, and give a character to otherwise uninteresting places. I need scarcely add that the plant is nearly hardy, and that it revels in damp and shade.—T. W.

Chirita sinensis.—This is an evergreen, herbaceous, Chinese plant, the leaves of which spread not unlike those of a Gloxinia; the flowers, which are blue, are also somewhat similar in shape to those of a Gloxinia, but they are produced in bunches on the extremities of erect stalks that rise well above the foliage, and, as these are thrown up freely, the plant has a very effective appearance. It blooms in summer, and is a useful subject for conservatory decoration. It thrives well in a mixture of peat and loam, to which has been added a little leaf-mould and sand; when in active growth it must not be allowed to want for water, or the advancing flowers will be injured. After blooming it should be kept somewhat drier at the root, but, owing to its evergreen character, it must not be allowed to get so dry as to cause the leaves to flag. It does best in a warm, greenhouse temperature. There is also a variegated form of this plant, the leaves of which are handsomely marked.

Blue-flowered Greenhouse Plant (Chirita sinensis).

Anthericum variegatum.—This plant is well worth growing for furnishing small vases or for conservatory decoration. It was introduced from the Cape of Good Hope. It is of a hardy character, and in variegation and habit closely resembles Pandanus Veitchi. It is, however, much more easily cultivated, and its foliage never fails to assume a bright grassy green colour, beautifully striped and margined with creamy-white.

The Effects of Lime-water on Chrysanthemums. — In answer to the inquiries of "A Novice in Horticulture" respecting the effect of lime-water on pot plants, allow me to give my experience. I noticed in a recent number of GARDENING ILLUSTRATED an article on Chrysanthemums in which the writer finishes by saying, "If there are worms in pots give a soaking of lime-water, &c." Having a good collection of plants in pots, in some of which I could see there were worms by the casts, I made some lime-water in the usual way, and, to be explicit, will say how: One pennyworth lump of lime was slaked in a large pan, and then cold water was poured on it, the pan filled, then stirred, and two days after when quite clear with quite 1 ft. of clear water above deposit, a can was filled with it, and it was given to the plants—result, a couple of worms came to the surface. Now for the after effects. The plants have been ruined by the application; the leaves, which were perfect and growing from the bottom of the stem, became flaccid, yellow, spotted, and gradually dried up, and are still doing so. The buds ceased to expand, and though under glass, plenty of air, warmth, and proper management, they are only now just moving a little, nearly a month stationary, and, considering they were for our local show, splendid plants and the choicest varieties, you can imagine my feelings. I should be glad to know if there are fellow-sufferers.—TRIED ONE.

ROSES.

MARECHAL NIEL ROSE.

THE leading article in GARDENING ILLUSTRATED, October 30, stirs up pleasant memories of Rose growing and gardening of all kinds in an old Bangalorean, who for the last ten years of his service was able to do a great deal in raising the status of the native gardeners, and improving the practice of horticulture generally in the province of Mysore. I will content myself today with noticing the fact of Maréchal Niel having been found not to answer for profitable cultivation, on account of its being so shy a bloomer. But in the interest of the amateur, I should like to give a brief description of its growth at Bangalore, where it has found a most congenial habitat, and blooms freely from July to December and well on into January in perfect beauty and fragrance, either as a pillar, umbrella-headed standard, or climber. It is difficult to say which suits it best, but perhaps a tall standard or an orchard walk, where one can look up into the golden blooms that hang down naturally, is most effective. Good feeding and just sufficient summer pinching to ensure a regular growth, with an occasional excision of gross shoots, &c., and keeping it judiciously supplied with water, so as not to allow of any alternation of wet and drought, is all that is really required.

Like the Tea and Noisette class generally, it does not stand the knife well, and the shaping is done by turning in where possible objectionable shoots, and stopping here and there as required. We have at Bangalore naturally a good, red, sandy loam of basaltic origin that is highly manured, and although the Maréchal Niel requires a little more scientific attention than Gloire de Dijon, Devoniensis, Cloth of Gold, and Lamarque, which flower in profusion

almost uncared for, it highly repays the extra trouble. With such treatment it revels in the sun in any place where it is sheltered from strong wind, to which it is very sensitive. About January 20 the dry easterly wind sets in during the day, which scorches up the flowers, and no more are seen till July.

With high feeding, soil renewal, judicious watering and handling, and a careful and frequent stirring of the surface earth to prevent its caking—all points on which the native gardeners at Bangalore rely for success—the shelter of glass would enable the amateur probably to bloom his Maréchal Niel more than "the one week in fifty-two" spoken of at page 412.

Roses at Bangalore are chiefly grown in pots, for convenience of carriage to exhibitions, as a precaution against white ants, for economy of space and superintendence, and for a concentration of show flowers. Considerable ingenuity is exercised in this display, an account of which, if acceptable, will be forwarded for publication. When asked about the climate of Bangalore, it is not an unfrequent answer: "Roses and Apples all the year round; Strawberries and Peaches from Christmas to June; and Bougainvillea spectabilis and other magnificent climbers in the grandest profusion of colour in January and February." This last remark reminds me of Mr. Boscawen's success with the Bougainvillea glabra, which flowers so well at Malta in January, but where in 1877 they so ignorantly pruned it. The plant needs a dry, warm climate. It will hardly flower at Madras, and with all Mr. Boscawen's skill and care he will hardly keep it alive in winter without shelter.

J. P.

Scrambling Roses.—Of scrambling Roses among the most common and the hardiest are the Ayrshire Roses. These are all double or semi-double, and the best of them are white or of a pinkish colour. There are hardly a dozen varieties altogether, and most of them are worth growing for the sake of variety. About equally hardy and useful for the same purposes is the Evergreen Rose, so called on account of the length of time it retains its leaves in winter. There are several good varieties, and they are vigorous and rapid growers, and need little or no attention except thinning when they are trained to pillars or walls. In rustic situations they need not be meddled with at all. To these may be added the Boursault varieties, a few of the Bourbon kinds, of which Souvenir de la Malmaison is the best example, and Gloire de Dijon and Maréchal Niel among the Tea-scented class. The last two are worthy of all the attention that can be bestowed upon them. Gloire de Dijon comes in early and goes out late, the second growth often producing flowers in abundance late in the season, and in the south the Maréchal Niel does well either on a wall or as a rambler in the open ground.

Soil for Potting.—No one need be short of a suitable compost for potting purposes who has clay for a staple, and can find sufficient sand and thoroughly decayed vegetable mould, whether from Grass, leaves, or litter, to mix with it. The common soil of the garden is the only loam which many can procure, and with such material at their disposal they need not complain. To get it in good condition they should obtain it from a quarter that has been rough dug and exposed to the frosts, which reduce the most tenacious clods to a fine meal, and it may then be shovelled up in that condition very dry and stored in the shed, when it will always be fit for use. Such a soil, with the usual additions in the shape of manure, sand, and leaf-mould, according to its texture, may be employed without any hesitation for most greenhouse plants that require loam. All soils which have a tendency to settle down into the consistency of putty—and even turfy loams, if heavy, do this eventually—are unfit for plants alone, but add sand in sufficient quantity, and their tenacity is broken up, and you can almost do anything with them. The root action of plants is yet a comparative mystery to us, and cultivators have been, perhaps, a little too dogmatic on the subject of soils, and too particular, thereby engendering a timidity among the half-experienced, which has no doubt, in many instances, been an obstacle to progress, for people do not attempt those things, as a rule, which they are taught to believe they have not the means of accomplishing. There is little doubt that plants are distinctly affected by the character of the soil in which they grow, and particularly by its texture, whether it be hard or soft; but experience seems to prove that any wholesome soil, freely pervious to air and moisture, and containing the necessary elements of plant food in an accessible form, is a perfectly suitable root medium, whether prepared from turfy loam and peat, or more simple and easily procurable materials.—C.

ANSWERS TO QUERIES.

3519.—**Renovating Pear Tree.**—One good method of renovating an old Pear tree is by grafting, but this involves the loss of any fruit crop for two years at least; in the end the tree is so renewed that its life is prolonged indefinitely. The tree should be headed back to several strong clean branches late in March, and be grafted at once or a week or two later. If the wood to be grafted is large, two or three stout grafts may be used on one branch. In your particular case perhaps the proper thinning of the tree during the winter will be efficacious, as the prospects of a fine fruit season next year are so great, that you may share the general prospective plenty. Cultivate the ground around the roots. If these, however, have gone deep into the clay, so that the points of the branches constantly die, then there is little hope that the tree can be restored to a healthy state.

3522.—**Potatoes for Autumn Planting.**—Late Potatoes will be safer to plant than early ones, as a mild winter may induce the latter to push into growth too early. Magnum Bonum will do well for autumn planting, as also may Bresee's Prolific, but Snowflake is probably too tender. Try Victoria, Champion, Climax, and Schoolmaster. Plant in 3-ft. rows and 6 in. deep, and then lay over each row a ridge of soil quite another 4 in. deep. This will throw rain from off the rows during the winter, and will exclude frost. In the early spring this ridge may be forked down, and thus leave but a moderate thickness of soil for the growth to come through. We know of no real advantage to be gained by autumn planting, whilst the risks are many.—A. D.

3525.—**Unproductive Garden.**—Perhaps if other and earlier sorts of Potatoes were planted than late kinds, such as Champion and German Reds, both uncertain as to root produce in some soils, better results may follow. No doubt the great need of the soil is a heavy dressing of animal manure. It evidently wants stamina, and this can only be got by heavy manuring and trenching. Salt is useful in hot dry soils, but the great need is ammonia. Still further, strong animal manure affords a valuable stay in hot weather. Deep cultivation may do much good, and dressings of guano, soot, salt, and lime are not without value, but a heavy dressing of stable manure put on now and worked in would be of more service than all the others put together.

3526.—**Grafting Potatoes.**—The witness who before the Potato Diseases Committee told that body that grafting would produce new varieties was mistaken, but such information was largely in keeping with the nonsense told to the committee. Grafting Potatoes is a means of amusement, but no tangible results follow. It is performed in this way: Take tubers equal in size and shape, but of two different kinds, say one white the other red. Cut out of one the bud end in the shape of a wedge; then cut out the bud end of the other in the same way, and exactly the same size; then insert the wedges or crowns into the reverse tubers, and tie them in tightly, making the cut surfaces to meet. Take care to cut out all eye-buds from the stock tuber, leaving only those in the graft or bud crown. Plant at once as usual. The graft may absorb some of the juices from the main tuber, but it is most doubtful, and no change is obtained. Grafts may also be made by starting two tubers, and when the shoots are high enough, slicing a piece of the side off each stem and tying them together. These should be grown in pots.—A. D.

3522.—**Holes in Pears.**—I have not the least doubt that the holes in the Pears which "R. D." complains of are made in the first place by birds; after that woodlice, flies, and earwigs get inside. As a Pear once perforated is simply useless, some year ago I adopted the following plan, which I have practised ever since with success: Take a card of the size and texture of a lady's visiting card, punch a hole, clean out in the middle of it nearly ¼ in. in diameter, and then slit the card from one end up to the hole in the middle, pass this card over the stalk of the Pear until it passes through the hole in the middle of the card, cross the two ends of the card and stick a pin through, and a most complete bird puzzle is formed. This plan is only practicable in the case of espaliers and pyramids where the fruit is within easy reach, when it quite repays the trouble. The plan has saved me some hundreds of fine Pears, and can be done very quickly.—S. J. U.

3202.—**Roses in Windows.**—At Princetown, Devon, the highest point in Devonshire, I believe, you can see in almost every window fine healthy Rose plants, mostly Teas, but many H. P. at least I saw them there at the end of May, 1879. They were as healthy and far more attractive than the average of window plants, and many were models of good cultivation. Princetown is the place where they have some fabulous number of wet days in the year, and it is in a very cold and exposed situation. Whether the scant sunshine, abundant moisture, and strong wind, *i.e.*, pure air, are together enough to account for the success of the Princetown people in growing Roses in pots, I know not, but I believe these said people are thoroughly in earnest over their Roses. To any one who doubts my statement, I say go and see for yourselves.—G. L. Whitby.

3582.—**Sea-sand to Mix with Soil for Plants.**—I have never prepared the sand prior to using it in any way. I procure it from an old heap standing outside a stable, where it is used for the flooring. I put some into a box and keep it in the potting room, where it gets gradually perfectly dry, same as silver sand. It has no doubt been well soaked with rain whilst outside and exposed to all weathers, and it is replenished at intervals of several months; fresh sand I have never used. Let those who fear its ill effects after this long exposure outside try a few experiments with it; a correct and practical proof will then be had.—H. B. S., *Ipswich.*

3580.—**Best Carnations.**—The twelve best Carnations according to my idea are Mars, Clipper, James Taylor, Admiral Curzon, Rifleman, Unexpected, Dan Godfrey, Falconbridge, Dr. Foster, James Merryweather, John Bull, J. D. Hextall. The twelve best Picotees—Royal Visit, Brunette, Alliance, Mary, Miss Horner, Thomas William, Edith Dombrain, Zerlina, J. B. Bryant, Mrs. Allcroft, Mrs. Payne, Minnie. Fancies and yellows—Gazelle, Congress, Lady Aitchison, Alice, Flavius, Titania. Cloves—Fire-eater (scarlet), Lady of Avenel (white), Rosa Bonheur (pink), Coroner (scarlet), Imperial Purple (purple), Sulphur King (yellow). "Burns" will find that these (or a selection from them) will give him a lovely collection of well-known flowers. Of course, they do not comprise the highly expensive novelties, but for show, table, or bouquets, he could not have better varieties. They should be got at once, put into 3-in. pots, and wintered in a cold frame, the pots bedded in Cocoa-nut fibre refuse.—Girofle.

3585.—**New Roses.**—I think the following are the best six H.P. that have been sent out during the last six years, viz.—Comtesse de Serenye (Lacharme), 1874; Monsieur E. Y. Teas (E. Verdier), 1874; Star of Waltham (Wm. Paul & Son), 1874; Duchesse de Vallombrosa (Schwartz), 1875; A. K. Williams (Schwartz), 1878; Constantine Tretiakoff (H. Jamain), 1878. The first four are now well known and generally admitted to be amongst the best for exhibition, A. K. Williams is one of the best Roses we have, and will be a great favourite when fully known, and Constantine Tretiakoff is distinct and altogether a most desirable variety. There are a few other new Roses which well deserve to be named, and they are as follows: Mrs. Laxton (G. Paul & Son), 1878; Duchess of Bedford (Wm. Paul & Son), 1879; Countess of Rosebery (Wm. Paul & Son), 1879; and lastly, Julius Finger (Lacharme), 1880, which is introduced as and promises to be an improvement on that grand Rose Captain Christy (Lacharme), 1873. —William Walters, *Burton-on-Trent.*

3527.—**Large Strawberry**—The large Strawberry referred to is, perhaps, that once known as the Great Exhibition, a huge, but worthless kind, or it may have been Kittey's Goliath. Autumn fruiting is not, however, a natural characteristic of any garden Strawberry, but is the result of some accident in culture; thus plants forced in pots early in the year will, if planted out in May, often bloom and fruit freely in the autumn.

3528.—**Rose Not Flowering.**—The best course to adopt with a strong-growing Gloire de Dijon that does not bloom would be to bud it again with the same kind, or if planted on a south wall with Maréchal Niel. Both of these kinds, as well as most of the strong-growing Tea Roses, are best fitted for south walls.

3529.—**Protecting Roses.**—Very little is to be gained by endeavouring to protect Rosebuds formed now. It is not probable that these would bloom in the spring if protected ever so much. If the plants were in a house and a gentle heat kept up they would expand the blooms, but in a cool house would lose them, therefore no good result can follow any attempt to protect them through the winter. You will find it desirable to cut away this late growth next spring, and get the wood to push afresh from dormant buds.

3534.—**Watercresses in Frames.**—For this purpose a quantity of young-rooted pieces should be obtained at once and be dibbled out into good, rich, porous soil, in a frame about 9 in. from the glass. It is obvious, however, that if very hard weather sets in, there will be no growth unless the frost can be excluded and a little warmth kept up. When watered in fine, open weather, slightly tepid water should be used to induce growth. After February, no doubt, plenty of gatherings could be got, but the waterings must be frequent.—A. D.

3531.—**Killing Stumps of Trees.**—Bore a hole into the stump large enough to hold a pennyworth of aqua-fortis, and then pour it in. This will effect the purpose.—A. W. FARMER.

3589.—**Pruning Pear Tree.**—*V.*—Any time after the leaves have fallen. Cut all shoots made during the year to within two eyes of their base. Your best plan would be to visit a gardener and let him explain it to you, or you may do serious injury to your tree.

3590.—**Variegated Hydrangeas.**—I have a variegated Hydrangea which has grown rapidly during the summer. Its lower leaves are now turning yellow and falling off. Ought it to be cut back like the common Hydrangea? and if so, when?—F. JACKSON. [If you want it to remain a dwarf bushy plant, cut it down in spring when the leaf-buds begin to burst. Keep it rather dry through the winter.]

3591.—**Liquid Manure for Apple Trees.**—Is it advisable to give liquid manure to Apple trees at this time of year? They are in an orchard from which the Grass is mown many times during every summer.—B. J. C. [During summer when the trees are in full bearing it would be beneficial; now it would be partly wasted.]

3592.—**Wintering Fuchsias.**—If Fuchsias are wintered in a cellar, are they best kept quite dry or little water given?—ZARA. [A little water now and then should be given if the soil gets very dry.]

3593.—**Outdoor Fuchsias.**—Are Fuchsias best cut down and covered over? or should the stems be left and the covering put round?—ZARA. [Leave the stems till they die, then cut them down. Cover the roots up with ashes.]

3594.—**Chrysanthemums Failing.**—I have a large number of all sorts of Chrysanthemums in pots, but they don't appear to be doing well; the leaves at the bottom of the stems seem dead. I have had the plants in the house now about three weeks, and have watered them with manure water two or three times, and about the same number of times with ordinary water. The buds are numerous, but I don't think even they are properly healthy.—H. B. [If you have them in the dwelling-house they are probably suffering from want of air. If in a greenhouse they ought to do well, unless you have overwatered them.]

3595.—**Lilium auratum.**—*H. B.*—Now the stem is dead remove most of the soil from the bulb, and re-pot it in good turfy loam and rotten manure and sand. Keep it where frost will not reach it, and do not water it until growth appears, unless the soil becomes very dry.

3596.—**Begonia Leaves Curling.**—*H. B.*—The spotted-leaved Begonias require a warm greenhouse at this time of the year. If they are in a cool place the leaves are sure to curl. Keep the plants rather dry through the winter, and cut them back slightly in spring if you have no heat in which to place them.

3597.—**Plants Becoming Drawn under Glass.**—*H. Ward.*—The practice of placing a square of glass over seed pots or pans is a good one, but when the seedlings are well up the glass should be removed, and the pans or pots be placed on a shelf close to the glass of the greenhouse, otherwise they will get drawn.

3598.—**Raspberries not Fruiting.**—What treatment should I pursue to get my Raspberries to bear? They are in rich, damp soil, some trained to stakes, some to wire. The canes are from two to five years old. They flower well, but when in blossom the suckers come up vigorously and overtop the blossoming canes, which turn yellow and form no fruit. The suckers surely should not sprout so early; the whole bed would be full of them were they not cut back.—W. A. A. [You have been cutting away your fruit-bearing canes and leaving the old and worthless ones. The system of Raspberry culture is this: Remove all old canes in autumn, and select enough young ones made during the summer to take their places, removing the remainder. The next year these are cut away and so on.]

3599.—**Wintering Solanums.**—*Enquirer, Liverpool.*—If you have well-established plants they may be wintered safely in an ordinary sitting-room if they are secure from frost. They will need to be watered with tepid water when the soil is getting dry, giving enough to thoroughly soak the whole of the soil. Watering at regular intervals, whether a plant wants it or not, is the cause of the loss of hundreds of window plants. A sprinkling overhead occasionally to free the leaves from dust will be an advantage.

3600.—**Tough Celery.**—*F. H. F.*—This is often caused by being grown in poor, dry soil. To have crisp Celery, rich soil and plenty of water in dry weather are necessary, and from the time the seed is sown till the Celery is finally blanched it must be kept growing without a check.

3601.—**Watering and Airing Plants.**—*Bot.*—Such plants as Geraniums, Fuchsias, &c., require to be watered in winter only when they are really dry. Air should be given whenever the weather is fine, and damp should be expelled by fire heat, a temperature of 40° at night and 45° by day will be ample. As regards treatment, you can only manage a mixed collection of plants in the same house by reading GARDENING regularly, and by experience ascertaining the requirements of each plant.

3602.—**Planting Clematis.**—*C. H.*—If the plant is a small and weakly one, you had better wait till March or April before you plant.

3603.—**Wireworm in Pots of Lilium auratum.**—*C. H.*—We should advise you to shake the soil from the bulbs at once and pot them in soil which is free from wireworm. Turfy loam or peat and leaf-mould or rotten cow manure make a good compost for them.

3604.—**Bamboo Stakes.**—*A. B. C.*—Apply to some of the dealers in such articles who advertise in our columns.

3605.—**Insects on Ferns.**—*G. T.*—The insects are thrips. Cut off the worst fronds and sponge the others two or three times with Tobacco water and soft soap at intervals of a few days.

3606.—**Insect on Vine Leaf.**—*M.*—Thrips.—Sponging with clean water is the only safe remedy in the case of Vines. The rods should be painted after being pruned with a mixture of soft soap, soot, sulphur and clay, or Gishurst compound—this will be a partial preventive.

3607.—**Vallotas Not Flowering.**—I have a pot full of Vallotas which, until two years ago, gave me the utmost satisfaction in respect to bloom, but about that time I shifted them into a larger pot, and, although quite fresh, they have never since bloomed. What can I do with them?—GREENOCK. [You over-potted them. When the pots get filled with roots the plants will no doubt flower again. Keep them rather dry through the winter, then place them in a moist heat, and they may flower next summer.]

3608.—**Spent Whitening for Soils.**—*J. W.*—We presume you mean chalk. It will be beneficial to clayey soils, but not to light sandy soils.

3609.—**Uses of a Cellar.**—I have a large, dark cellar, fairly ventilated, and not very damp. Can I turn it to any use?—HYSSOP. [Rhubarb roots or Seakale, placed in large pots or boxes of soil, may be put in the cellar in successive batches. Keep the cellar dark and close.]

3610.—**Berberis Darwini.**—*R. H. P.*—Prune it back in spring. It is easily raised from seed.

3611.—**Cutting Laurel Hedges.**—*R. H. P.*—Cut back hard in January or February.

3612.—**Espalier Apple Trees.**—*R. H. H.*—The only advantage wire trellises possess over wooden ones is that they last longer and look neater. Galvanised wire is said to be injurious to fruit trees.

3613.—**Ferns in Rooms.**—Will you kindly give me information on the treatment of Maiden-hair and other Ferns? having just purchased a lot, and having no greenhouse, I am obliged to keep them in my dining-room.—W. H. B. [If you keep them in the window where they will get plenty of light, and keep them free from frost, dust, the fumes of gas, and supply them liberally with tepid water when the soil is getting dry you may keep them healthy for some time. A large glass case would be an advantage; you could put the plants in it whilst the gas was burning, and it would also keep the dust from them.]

3614.—**Manure for Roses, &c.**—*Chole.*—Artificial manure is a great help to Roses and other plants, but it is not equal to good stable manure.

3615.—**Temperature for Greenhouse.**—What temperature should a greenhouse be kept at containing Geraniums, Camellias, Ferns, Primulas, Pelargoniums, &c.?—G. W. G. [Do not let it get below 40° at night unless the weather is very severe, nor above 45° unless very mild. During the day 5° higher.]

3616.—**Arable Land in the United Kingdom.**—*M. W. M.*—About thirteen and a half million acres, which includes corn crops, green crops, and uncropped arable land. An acre of Cabbage would cost to cultivate by the spade about £10 without reckoning manure or cartage, but including seed. We cannot answer your other question.

3617.—**Saving Onion Seed.**—*Cambridge.*—Select well-formed bulbs in spring and plant them in land well manured during the previous autumn or winter. Plant them in rows 2 ft. apart and 1½ ft. apart in the rows. When the flower-stalks appear place a stake to each, and when the seed turns black and shows signs of falling out of the husks, cut off the heads and place them on a sheet of paper in the sun to dry, taking care that rain does not fall on them. Clean and put in paper bags till wanted for use. A warm, sunny border is the best place for seed Onions.

3618.—**Filling up Gaps in Asparagus Beds.**—*Cambridge.*—March is the best time for this purpose.

3619.—**Planting Horseradish.**—*Cambridge.*—The best way is to draw drills 4 in. or 6 in. deep, and plant in them crowns or pieces of the root 6 in. apart, covering them 1 in. or 2 in. deep. When growing, fill up the drills with soil, and finally, earth the plants up like Potatoes. Deep, rich land is necessary for the culture of good Horseradish.

3620.—**Maréchal Niel Rose.**—I have a Maréchal Niel Rose in greenhouse in an 8-in. pot; it has made some shoots 11 ft. or 12 ft. long, and looks remarkably healthy. How must I treat it to insure a good bloom next spring? Must it be kept moist or dry? Will it require any pruning? and must it be re-potted or not?—INQUIRER. [Insert four or five neat flower sticks round the edge of the pot. Then twist the branches round the sticks. Give it plenty of water when in active growth, and early in spring a top-dressing of rich soil or artificial manure will be an advantage. A little weak soot water occasionally will also do good. Re-pot after it has done flowering.]

3621.—**Planting out Roses.**—*W. H. T.*—If you do not want to force the Roses into bloom early, the roots may be outside of the greenhouse, but if you can plant them inside you will have them more under control.

3622.—**Manuring Flower Beds.**—*S. B.*—Manure is best applied in a decomposed state, but if applied now it may be used when half rotten.

3623.—**Pots for Orchard-house Trees.**—*J. S.*—For trees in large houses 18-in. pots; for moderate-sized houses 13-in. or 15-in.; for small compact bushes 11-in. If you get good trees at once they should fruit next year.

3624.—**Worms in Frames.**—I have some Calceolarias in a frame, and the worms keep forcing them out of the earth; can you tell me what to do to destroy them?—A. O. [Water the soil with lime water. Put a double handful of lime into a bucket of water, and when dissolved use it through a rosed watering-pot.]

3625.—**Lifting Vines.**—*Weekly Reader.*—You can successfully lift Vines five years old whilst you make a new border. Carefully lift the roots from the soil, and cover them up with mats, &c., so that they do not get injured by frost. When you have made the border lay the roots out regularly, and cut off any that are bruised. Perform the work during mild weather if possible. If the Vines have been forced early, do the work at once; if they have not been forced February, will be the best time. The Vines must be started gently as soon as the work is completed.]

3626.—**Jerusalem Artichokes Flowering.**—*W. E. A. Y.*—There is nothing remarkable in these flowering when planted in warm soil and in a sunny situation.

3627.—**Root-pruning Apple Trees.**—I have a splendid young Apple tree which has made a wonderful lot of wood. When is the proper time to prune the roots? and how?—E. W. [Lift the tree carefully; then cut back to at least half their length all the strong roots. Be careful not to injure the fibrous roots. Plant again at once.]

3628.—**Original Dahlia.**—*Constant Reader.*—The name of the original Dahlia is D variabilis. We do not know where it can be obtained, but probably at any nursery where Dahlias are largely grown.

3629.—**Passion-flower.**—*Fairfield.*—As shoots are rising from the bottom you may safely cut out old wood if you desire to do so.

3630.—**Pollarding Acacias.**—I have two Acacias in front of my sitting-room which are now about eight years old. They have grown so luxuriantly that they are now altogether too large. Would it do to pollard them? and if so, when? and what precautions ought to be observed in doing so?—A. R. [We would cut back some of the longest and largest branches, but not pollard them.]

3631.—**Cutting Branches off Pear Tree.**—I have a Pear tree, a large branch of which overhangs my neighbour's garden. Would it do to cut it off?—A. R. [Yes.]

3632.—**Propagating Marguerites.**—*Enquirer.*—Cuttings of the young shoots strike any time during summer if placed in sandy soil under a bell-glass. In spring they require a little heat.

3633.—**Layering Magnolias.**—*A. W.*—Any time during summer or autumn. Bend down the shoots and slit them upwards with a sharp knife, so as to leave a kind of tongue to the layer. Peg this down firmly in sandy soil, and cover over to a depth of 2 in. or 3 in. Keep moist during summer.

3634.—**Caterpillars and Slugs.**—*M. A.*—Well dig or trench the ground and apply a good dressing of lime. Leave the ground rough on the surface, so that the frost may penetrate it. We know of no other way of preventing caterpillars and slugs in summer.

3635.—**Uses of Cellars.**—I have four large dry cellars, one of them very light and having a stove in for the greenhouse. What are the most useful things I can grow in them during the coming winter? I have planted my bulbs and set the pots in a layer of ashes in the cellar. Am I to lay anything over the pots or leave them uncovered?—M. F. [If you have plenty of horse manure you might grow Mushrooms. You can force Seakale, Rhubarb, and Chicory in them. The bulbs would be better with small flower-pots inverted over them.]

3636.—**Renovating Vine Border.**—*Fairfield.*—This is a good time of year for this work.

3637.—**Washing Fruit Walls.**—My garden walls are washed every year with a mixture of cement, lime, and copperas. The fruit trees have always been unfastened, but as that entails a deal of work, would the above mixture injure Peach trees if washed over them?—ELEANOR. [We would advise you to continue your usual practice.]

3638.—**Pruning Rose Trees.**—*R. T. H. M.*—Let them remain till spring; before that time we shall doubtless publish articles on the subject.

3639.—**Fancy Dahlias.**—*True to Name.*—Self-coloured Dahlias are not "Fancys," and are therefore of no use to propagate from when "Fancys" only are needed. You cannot make a single Dahlia come double.

3640.—**Treatment of Annuals.**—I planted about three weeks ago Nemophila, Virginian Stock, and Pansy seeds, all of which are now ½ in. out of the ground. What steps must I now take to preserve them for spring-flowering? Also, may I plant out in the open some Polyanthus seedlings raised in the house?—E. O. B. [Thin out the plants to 3 in. apart, and cover the ground with a little Cocoa-nut fibre or leaf-mould. The Polyanthuses would be better pricked out into boxes, and put in a frame till spring.]

3641.—**Wintering Ageratums.**—Kindly say how Ageratums ought to be treated. I have some cuttings and a great many large plants. I have a frame and small unheated greenhouse.—F. H. B. [Pot them and place them in the greenhouse; keep them free from damp and frost. You may save them, but it is doubtful.]

3642.—**Wintering Coleuses.**—*F. H. B.*—If you have not a warm greenhouse or frame throw the plants away, and get a few more in spring.

Silver Sand.—*C. F.*—Reigate supplies a greater amount of silver sand than any other place we know of.

Moving Asparagus Plants.—*C. S.*—Wait till March.

B. R. H.—Send your address and we will advise you.

Names of Plants.—*G. H.*—1, Beurre Capiaumont; 2, Winter Nelis.——*Richmond.*—No enclosure.——2, *Grasses.*—1, Anthoxanthum odoratum; 2, Cynosurus cristatus; 3, Holcus lanatus; 5, Agrostis alba; 6, Linum catharticum.——*Amos.*—Francoa sonchifolia.——*G. Sandford.*—Campanula muralis.——*E. D. T.*—Lamium maculatum; we do not name varieties of Fuchsia.—*Greenock.*—The leaves you send appear to be those of Lilium candidum (the Bourbon Lily).——*Park.*—A species of

Echeveria ; cannot name without flowers.——*M. Brown.*—Cassia Sophora ; keep it in the greenhouse or window in winter ; cuttings strike in spring or autumn.——*F. R.*—A species of Solidago; cannot name from such scanty material.——*Busy Bee.*—Erythrina Crista-galli.——*N. Porter.*—Helichrysum bracteatum ——*J. Jarvis.*—Hoya carnosa ; we can assign no cause for its dying without knowing what treatment it has received.——*Subscriber, Barnsbury.*—Escallonia macrantha ; from top of shoots in spring, sandy soil in a warm frame, or in August in open ground under a bell-glass.——*Zara.*—No plant enclosed.——*Ashtead.*—1, Brooke's Pippin ; 2, Court Pendu Plat probably ; 3, not known ; 4, Mother Davis ; 5, not known ; 6, Hawthornden ; we cannot name Apples or Pears with certainty from single specimens.——*H. H.*—Kindly send us better specimens.

QUERIES.

3643.—**Draining a Garden.**—I have a piece of ground attached to my house (I cannot as yet call it a garden) 80 ft. by 18 ft., which consists of clay, and which I should like to drain, and should also like to know the best way to go about it, as it is not practicable to drain it into the sewer. I could open the ground at the bottom and make a ditch to receive the drainage, but am at a loss to know how to get the water out when the ditch becomes full. Will any of your readers' inform me of a simple and cheap remedy ?—W. G.

3644.—**Unsatisfactory Vines.**—I have a Vinery 62 ft. by 14 ft., span-roofed, the borders of which were made good last year. My Vines, which have been planted twenty years, have since slightly improved. When they break they do so with a white down on the leaves, and the leaves turn off with a black-brownish appearance. The same on the wood; also rusty like spots on the leaf ; air roots on the canes very thick. I shall be glad if any reader can give me some instructions.—J. R.

3645.—**Deformed Cyclamen Flowers.**—What is the cause of Cyclamen flowers coming a bad shape? mine are very large, but some of the blooms are almost flat. They are young bulbs, the first time of blooming, and seem very healthy.—WOODCOCK.

3646.—**Planting Gooseberry Trees.**—I am anxious to plant some Gooseberry bushes immediately, and I wish to know whether the subsoil should be manured in forming a permanent bed for them, and being quite a novice, I should like to receive any useful hints as to planting, &c. The top soil is a good fibrous loam, the subsoil is a sandy loam, inclined to clay in some places. The ground slopes towards the north.—W. H.

3647.—**Leather Shavings as Manure.**—What is the best way to convert leather shavings and the refuse from a currier's shop into manure for the garden ?—H. Y.

3648.—**Treatment of Deutzias.**—I have got a plant named Deutzia which used to flower and smell very sweet; it is a small bush. For the last year or two it has not bloomed or grown at all ; the leaves seem to curl downwards and half wither. Can any reader give me a few hints respecting it.—BOT.

3649.—**American Water Melons.**—I shall be much obliged if any reader can inform me what is the proper culture of the Water Melon in England. I was in Canada and the United States during part of August and September this year, and they seemed to grow almost like a weed there amongst Potatoes and other crops. The price for a very large one was only twopence or threepence.—H. E. HULL.

3650.—**Beet and Parsnip Wine.**—Can any one oblige me with a recipe for making Beet and Parsnip wine ?—J. B.

3651.—**Plants to Withstand Gas.**—Will some one give me a list of hard-leaved plants that would live in the window of a room where gas is burnt ?—H. R.

3652.—**Plants for Screens under Tall Trees.** I have a row of Elm trees close to the road, under which I wish to get a thick evergreen hedge or narrow shrubbery as a screen, and I should prefer it composed of different shrubs. Will some correspondent give me a list of some that would thrive in this situation? The Escallonia does well here, and I purpose trying that amongst others.—R. W. P.

3653.—**Chinese Miniature Plants.**—By what means do the Chinese produce miniature plants ? Real information on this subject would be acceptable to readers of GARDENING ILLUSTRATED.—J. P.

3654.—**Drying Manure.**—If animal droppings are left to dry in the sun, do they lose their manurial properties ? and to what extent ? Some say they do so entirely, others say not.—J. P.

3655.—**American Cranberry.**—In what kind of climate, as to drought and frost, does the American Cranberry succeed ? and is it propagated from seed ? If so, where is it procurable for trial in some of the hill climates of South India ?—J. P.

3656.—**Propagating Bougainvilleas in India.** How are Bougainvillea plants propagated here ? In Bangalore, though the B. spectabilis blooms amid such grand surroundings of purple and gold, it yields no seed, and is propagated by layering.—J. P.

3657.—**Striking Rose Cuttings.**—Is it too late to strike Rose cuttings now if great care is exercised ? If not, every suburban gardener might at least strike a few dozen under a large hand-glass, which would well repay the trouble in little flowering bushes for window decoration next June and July.—J. P.

3658.—**Dried Lavender.**—Can any one tell me where this can be procured ?—SAFFY.

3659.—**Leucophytum Browni.**—Can any one tell me how to propagate and treat this plant through the winter ?—HEREFORD.

3660.—**Fern Case and Aquaria.**—Being about to construct a Fern case with aquaria combined (wood), I should feel grateful to any reader who would assist me with a good design. I want one 3 ft. or 4 ft. long. I shall want all details, sort of wood best adapted, &c.—W. T., *Glasgow.*

3661.—**Clematis Henryi.**—I have one of these on a west wall, only planted there in the spring. What treatment does it require ?—T. H.

3662.—**Tulips for Outdoor Planting.**—Which are the best single and double Tulips for outdoor planting, to flower in March—colours crimson, gold, and white, and about 8 in. or 10 in. high?—S. B.

3663.—**Zinnia elegans.**—Will some one tell me the best way to sow and grow Zinnias for exhibition ?—W. W. W.

3664.—**Silica Paint.**—Where is this to be procured ? I have a fine concrete floor to conservatory off my drawing-room. Will this paint stand the drip from flower-pots, walking, &c. ?—H. A. D.

3665.—**Rabbits Gnawing Forest Trees.**—I should be glad if some reader could inform me of some solution for dressing trees, which would prevent rabbits gnawing the bark, and not injure the trees. Also where to obtain it.—A. G.

3666.—**Begonias and Calceolarias Dropping their Buds.**—Will some one suggest the cause of the blooms dropping from my herbaceous Calceolarias and Begonias immediately after watering ? When I let them go dry the bloom hangs on till withered. In the summer my Calceolarias on being watered would drop a dozen or more of the best blooms within half-an-hour, and now my pink Begonias are just the same, except that the Begonias drop the small buds. I water just sufficiently to show through the bottom of the pots. They are in a small heated greenhouse, average temperature 50°.—L. M. T.

3667.—**Violets in Autumn.**—How can I manage my Violets so as to have them in bloom early in the autumn ? I have five or six varieties, all warranted to bloom from October to December, and have paid every attention to the planting, &c., but only get half-a-dozen blooms at a time off a large bed.—A CONSTANT SUBSCRIBER.

POULTRY.

Treatment of Fowls.—I am often surprised at the difficulties experienced by your correspondents in the management of their poultry, and at the unfortunate diseases to which they appear to be subject. We keep nearer one hundred than fifty head of poultry—fowls, ducks, chickens, &c., of all ages and several kinds, and all running together and cross-bred. They are kept for the use of the house ; that is, home consumption, and are fed upon Barley, Indian Corn, Rice, and Barley-meal mixed with water. They have a run of several acres of Grass, and they also have scraps from the house ; they are not subject to any disease whatsoever, and require neither physicking nor coddling. Fowl keepers should remember that a fowl is not a cooking animal, like man, and therefore I am of opinion that it does not require cooked food, and they should also remember that it has a gizzard to grind its hard food. All it requires for health is a dry place to roost in, a good run, water, and some dry Corn. It should never be put up to fatten, but always be in condition for the table when required. Some years back I made some experiments in hatching, being of opinion that a hen knew best how to manage her eggs and bring the chickens from them. I had as many as twenty-one chickens from twenty-one eggs put under a hen. The number of eggs should be apportioned to the size of the hen. My plan was simply this, to put the hen and eggs under a coop on the Grass, or if wet weather when put to sit under a shed, so that the ground may be dry under her ; put some water in a small jar, and some Corn in a saucer into the coop and put a board up in front with a heavy stone against it, to keep the hen from being interfered with. I used to see daily that there was water and Corn, but never meddled in any way with either hen or eggs. I remember the first experiment was on the lawn, with a fine cross-bred hen and 21 eggs. One day when taking a peep at her—the eggs were scattered all over the ground under the coop—I thought to myself, here's an end of my experiment ; she has got tired of the eggs and ceased to sit ; but, however, I put up the board and looked again some time after, when, to my astonishment and delight, not an egg was to be seen ; they were all under the hen, and she looked comfortable and contented, the result being that she hatched all the eggs, viz., 21. After that I always adopted the same plan, and if the eggs were good, with the like success. The simple fact is, human nature is too fond of meddling and doctoring, and fancies it knows very much more than it really does, and thinks that other animal nature does not know anything ; in fact, that a hen does not know how to hatch its own eggs. I may add that the chickens were never meddled with, but left entirely with the hen.

Fowl-keeping in Small Spaces.—"T. F." seems to have chanced upon an unfortunate strain of Brahmas which are "perpetually wanting to sit," &c. The fact is, the Brahma is the most abused fowl in this respect that I know of. The general run of Brahmas do not get broody half so frequently as Cochins, and if this quality be discouraged by a little careful selection, a strain having the tendency in a very moderate degree will soon be obtained. Hamburghs of all sorts are peculiarly unsuitable for closely confined spaces, although individual cases may prove the exception to the rule. The very best birds to keep in a small place to produce eggs during the winter months are produced by mating a stout Houdan cock with dark Brahma hens ; the pullets generally do not sit, lay freely, and produce large eggs. This is practical experience and not theory.—FLEUR-DE-LIS.

Cross-breeds in Poultry.—Will any one who knows kindly tell me whether a creve-cœur cock and black Hamburgh hens would make a good cross ?—L. G

BEES.

"J. W." should transfer his bees to a bar frame hive, which can now be purchased cheaper and is more serviceable than straw skeps. The bees will do best for the winter if confined with dummy board to a few frames only for wintering. The frames should be covered over with a piece of strong calico, and above that some material that will keep the bees warm, whilst allowing all generative moisture to escape. Some use common household flannel, chaff bags, &c., but I have found it more convenient to use chaff a few inches deep, which can be confined to its place with a bottomless box ; but the hives should, if constructed properly for feeding or supering, do without any other box. If possible, some driven bees should be obtained to strengthen the stock, when, if the queen is present, all will go well if fed continuously and not too fast. If "Novice" will wait patiently I will endeavour to comply with his wishes before the next honey harvest. "Weaver" would do well to feed his bees continuously with syrup, arranged so that only one bee can feed at once. There are several fancy feeders sold for this purpose. The plan that I have found to answer best is to fill an ordinary pickle bottle with syrup, then tie it over with a piece of bladder previously softened in warm water ; prick one fine hole in it, and place on the feeding hole. This if protected from weather may remain on all winter. Care should be taken that the sugar is boiled properly, so as not to crystalise. The syrup I use is made of the best lump sugar, which I find cheapest in the end, to which I add five pints of water ; it should be boiled a few minutes, then 2 oz. of vinegar and a small spoonful of salt added, boil a few minutes longer and set to cool. If when cold it shows any sign of crystalising, more water should be added, and boiled up again. For spring and summer feeding a thinner syrup should be used, and at certain times Pea meal given. BAR FRAME.

Feeding Bees.—"A Weaver" need not feed his bees until February or March. Should the winter be frosty he may get through without any feeding, as they eat but little, if any, in frosty or very cold weather. In February weigh them, and should they be not more than 6 lb. or 7 lb. in weight, feed gradually at the top of the hive if possible with sugar and water boiled to the consistency of thin syrup ; at the same time keep them warm by wrapping any old sack or other material around the hive ; keep them as dry as possible. If the spring be warm and the stock strong, they will swarm early in the month of May.—APIARY.

HOME PETS.

Canaries.—Can any of your subscribers tell me what is the matter with my canary ? It appears to be in good health, but it breathes so laboriously that the act seems painful. What is the cause and cure ?—W. P.

Pigeon with Weak Wings.—I have a pair of magpie pigeons, and one of them has lost the strength in the wings. I should be glad if any one could tell me what to give it, as I do not want to kill it ?—LITTLE VIXEN.

Rabbits for Show.—W. G. Hackett may obtain all he requires of Mr. Tonkinson, Catherine Street, Doncaster, who is a noted breeder.—W.

Book on Rabbits.—*Monmouth.*—"General Management of Rabbits," 1s. 1d. post free. "Rabbits for Prizes and Profit," by Leonard W. Gull, 2s. 9d., post free from 170, Strand, W.C.

Teaching Parrots to Talk.—I have two young birds, one an African grey, and the other a green one from Jamaica. Will some one kindly inform me the best way of teaching them to talk ? Is it best to talk to them in the dark ?—F. M. A. S.

Difficulty of breathing in Canaries.—I have a canary which I am under the impression suffers from asthma. I should be obliged to any reader for a remedy ? I feed it upon ordinary seed, and likewise a little of Hartz Mountain food.—C. W. W.

GARDENING

REGISTERED FOR TRANSMISSION ABROAD.

TALL SCARLET LOBELIAS.

THESE are among the best of flower garden plants for autumn display, and though quite hardy in some soils they are best taken up yearly. They do not, however, require half the trouble bestowed upon them as is necessary with Pelargoniums and similar plants used for flower garden decoration. The foliage of the Cardinal Lobelia (L. cardinalis), which we now figure, is of a deep bronze colour, and therefore, even when not in flower, the plants are quite as attractive as many of the plants used in the garden for their foliage alone, Iresines for example. The roots should be lifted in the winter and potted, or may be grown in pots altogether, but should be treated as a hardy border plant during the summer, and have a deep, rich loam, well manured. The plants will keep well if planted up for the winter in a cold frame which has the protection of some covering in severe weather. The spring is the best time for propagation, when the plants have pushed a few inches of growth; the roots are then either divided, or the shoots are taken off at the base and struck in a gentle warmth. Lobelia fulgens, the leaves of which are deep green, tinted with bronze, is one of the most brilliant of flowering plants in September, October, and even November. It is hardier than the one just alluded to, but requires similar treatment. One rarely sees it in good condition, probably owing to the fact of its requirements not being sufficiently studied. It luxuriates, and will last in good condition for an indefinite period in a free, porous, well-drained soil; but where the soil is naturally of a cold, heavy description, the roots are liable to the attacks of a kind of canker. The plants succumb to the first period of inclement weather, and very often—much to the vexation and wonderment of the grower—altogether fail to show signs of growth the ensuing spring. The safest plan is, where any doubt exists upon the matter, to take the plants up as soon as they are done flowering, wash the roots, and lay them in a free soil in a frame. They then immediately make fresh rootlets, and are thus ensured against decay. The situation chosen for planting should also be sheltered. No better place can be found than amongst evergreen shrubs, where there is plenty of light, air, and space for their development. The cold nights and damp days of autumn do not appear in the least to dim the beauty of this Lobelia, the flowers being then produced as fresh, highly-coloured, and well developed as those which expand earlier in the season. Such plants as these which flower freely and brightly amongst the fogs and dark autumn days are very welcome, and are well deserving of some cultural care.

THE CARDINAL FLOWER (LOBELIA CARDINALIS)

Either or both kinds may be planted out in April or May either in groups or beds by themselves, or at intervals in beds of Pansies or other dwarf spring or summer-flowering plants. This is a good plan, as when the Pansies are out of bloom they form a green carpet, from which the tall spikes of brilliant crimson blossoms of the Lobelias will spring with excellent effect. When obtaining these plants from a nursery care should be taken o get them from a reliable source, as there are in cultivation some inferior kinds, which would disappoint the grower. The plants from which our illustration was prepared were grown in the garden of Leopold Rothschild, Esq., at Ascott, Bedfordshire, and were examples of culture rarely seen in the case of these Lobelias.

TOWN GARDENING.

Striking Cuttings.

Pots are better than boxes for striking cuttings in as a rule, except where a large quantity have to be raised ; then use a properly prepared frame, without pots or boxes, the soil being filled in to form a bed. 3-in. pots, or what are known as large 60's are the most useful size ; fill them nearly half full of drainage ; on that place a few Hops or a little Moss, and fill up to the rim with nice sandy soil, not sifted. When filled, stand nearly up to the rim in water till soaked through ; then set aside for an hour or two to drain. Make good large holes with a stick for the cuttings, pour a little dry silver sand into each hole for the base of the cutting to rest on, put in your cuttings, and fill up and around with silver sand, pressing them in pretty firmly. Then give a light sprinkle to settle the cuttings in the soil, stand aside till the leaves are dry, and then place in a frame or house, with or without heat as required. Keep them close, only admitting a little air for an hour in the morning or evening to dry the leaves and prevent damping until rooted, when gradually accustom to plenty of air, and when well rooted, pot off singly. Most cuttings, except Geraniums, must be shaded from hot sun until roots are formed, and in some cases after. Three or four Geranium cuttings in a 3-in. pot are enough ; these like a rather loamy soil to root in. For Fuchsias use only leaf-mould and sand, and put five or six or even eight cuttings in a pot. Petunias, Verbenas, &c., like equal parts of loam, leaf-mould, and sand. It is as well to let cuttings have a little sun morning and evening to raise the temperature of the frame, but shade as soon as the sun gets hot. They must also be kept moist, but not wet, and as close as possible, so that damping does not occur, till rooted. It is astonishing what numbers of things can be rooted in a simple box of any convenient size and 9 in. to 1 ft. in depth, half filled with drainage and soil, and covered over with a sheet or sheets of glass. During May, June, July and August, Fuchsias, Geraniums, Pelargoniums, Myrtles, and nearly all greenhouse plants will do well thus, and if the box can be kept in a greenhouse, will do better and strike sooner.

Many things root readily in Cocoa-nut fibre refuse mixed with sand. All cuttings should be growing when taken ; they should be cut clean off with a sharp knife, cutting just below a joint and in a sloping direction ; the lower leaves should be removed and the slip planted at once. As soon as the young roots are 1 in. long, or even less, pot off singly, and do not wait until the roots are a tangled mass, and have to be broken. After potting off, keep close for a few days again, until they are rooted out.

Plants for Outdoor Gardens.

For greater convenience we give three separate lists — the first containing those plants that will do well in any situation, however bad, with moderate care ; many of them indeed will grow almost anyhow and anywhere, though of course if carefully cultivated they will give better results. The second list contains the names of such as require more care and attention than the first, special soil, &c., to do well, or that would do well in suburbs or small towns. And the third list, such as cannot be made to grow at all in town air, or that will at best only drag out a miserable existence for a year or two, and give more pain than pleasure to their owners. After the lists we will take the most desirable kinds separately, and give instructions for their successful cultivation, with the soil most suitable for them, and so on. The lists are all arranged alphabetically for greater convenience. We do not strictly adhere to the botanical names, but give those by which the plants are generally known. The most suitable plants are marked thus (*), and those marked (†), though really perennials, are better treated as annuals.

FIRST LIST.

Trees.

Cherry, American double white
Elder
* Fig
* Lime
Maple (Acer). A. plantanoides and monspessulanum are best
* Plane

Shrubs.

Aucuba japonica
Cuba (variegated) Laurel
Cytisus cyprius (Gum Cistus)
* Euonymus
French Willow
Hawthorns will live and grow, but hardly ever flower
Lilac
* Ribes
* Sumach (Rhus)
,, Fern-leaved (R. glabra laciniata)

Climbing and Trailing Shrubs.

* Cratægus pyracantha
Ivy (Hedera) vars.
* Jasmine (summer flower, white)
Pyrus japonica
* The Vine
* Virginian Creeper (Ampelopsis hederacea and Veitchi)

Hardy Plants.

Aconite (Eranthus hyemalis) yellow
Asclepias tuberosa (Swallow-wort)
* Auricula
* Canterbury Bells
* Chrysanthemum (old early white and red are best)
Commelina cœlestis (Spider-wort)
Cowslip
* Creeping Jenny or Moneywort (Lysimachia nummularia)
Crocus
Daffodils
Delphinium (perennial Larkspur)
Dielytra spectabilis
* Evening Primrose (Œnothera Lamarckiana or grandiflora)
Everlasting Pea (Lathyrus latifolius)
* Hyacinth (wild)
* Iris (German and common yellow, also other varieties)
Lilies (white garden and Tiger)
* London Pride
* Michaelmas Daisies (perennial Asters)
Polyanthus
* Primroses
Rose Campion
†* Snapdragon (Antirrhinum)
Solomon's Seal
Sweet Williams (Dianthus)
Tritoma Uvaria (Flame flower)
* Thrift (Armeria)
Veronica (herbaceous, blue)—Speedwell

Half-hardy Plants Needing Protection in Winter.

* Calceolaria (shrubby)
* Carnations
* Chrysanthemum (show or exhibition varieties)
† Cineraria (maritima and candidissima)
* Dahlias
* Geraniums (zonal and Ivy-leaved, not tricolors)
†* Golden Feather (Pyrethrum)
†* Lobelias, both dwarf blue and herbaceous (cardinals)
†* Marvel of Peru (Mirabilis)
* Mimulus
†* Petunias
†* Pinks (Indian and Chinese)
†* Verbenas

Annuals.

* Amarantus (mel. ruber and varieties)
* Asters
Balsams
* Candytuft
Cannabis (Hemp plant)
Chrysanthemum (annual)
* Convolulus major and minor
* Corn flowers (Cyanus)
Eschscholtzia
* Helichrysum (Everlasting flowers)
Larkspur (annual)
Maize (striped Japanese)
* Marigolds (French and common garden)
* Mignonette
* Phlox Drummondi
Poppy
Silene pendula and varieties
* Stocks (German and Virginian)
* Sunflowers
Tropæolum (Nasturtium)
* Venus' Looking-glass
* Zinnia

SECOND LIST.

Trees and Shrubs, &c.

Amelanchier vulgaris
Barberry (Berberis Darwini, best)
Clematis (preferably montana)
Forsythia viridissima
Horse Chestnut
* Laburnum
Laurustinus
Lignum vitæ
Magnolia conspicua
Passiflora cœrulea
Persian lilac
Privet
* Poplar and Aspen
Sycamore
Syringa
* Wistaria

Hardy and Half-hardy Plants.

Campanula (pyramidalis and carpatica, &c.)
Ferns (hardy)
Foxglove (Digitalis)
* Fuchsias (some kinds)
* Gladiolus
Godetia (annual)
Heartsease (some vigorous varieties)
* Hollyhocks
* Hyacinths
Lily of the Valley (Convallaria
* Lupins
Pentstemons
Perilla nankinensis (annual)
* Phlox (perennial)
Pinks (garden)
Salpiglossis (annual)
Scabious
Stonecrops (Sedums, varieties of)
Tulips
Wallflowers

THIRD LIST

Includes nearly all Forest Trees, Oak, Ash, Elm, &c., in any smoky or thickly populated districts.

Shrubs.

Arbutus
Azalea
Broom
Guelder Rose
Heaths (Erica
Holly
Laurel

Plants.

Anemone
Coleus
Cuphæa
Daisies (Bellis)
Gentians
Hepaticas
Hibiscus
Jasminum nudiflorum
Linums
Pansies
Pelargoniums (zonal tricolors)
Portulacas
Primula acaulis fl.-pl., the spring flower
Ranunculus
Roses
Sweet Peas
Violets
Violas

(To be continued.)

Pansies in Towns.—The writer of the article on "Town Gardening" (p. 425) states that Pansies never do well in towns. Now, my experience is widely different ; in fact, I look upon the Pansy as one of the most valuable plants for the purpose ; it may be that they will not do quite as well as in the country, but just the same objection could be raised against any other hardy perennial. Let any one who wishes to test the matter for himself get a packet of good mixed seed and sow towards the end of March in boxes ; when sufficiently large to handle plant out the seedlings, and they will commence blooming in June ; from these select what are worth growing, and afterwards rely only upon cuttings, which may be taken almost at any time. My method, however, is to nearly fill a frame with light rich soil during September, and plant the cuttings in that ; the glass is only put on during foggy weather, and at night after November commences. I have thus plenty of strong healthy plants ready for planting out in the spring, when care is taken to disturb the roots as little as possible ; in other words, they are lifted with a good ball and planted out. The after treatment consists in keeping the plants from going to seed, and helping with a little manure water during the summer. Mulching is also of assistance to them, especially if planted in a sunny situation, and they require plenty of water. It is quite waste of money to buy what are sold in the London shops and streets as Pansy roots ; no plant with such delicate root fibre could be expected to do well after the treatment they get. Raise your own plants or buy them from where you can see them taken direct from the ground ; treated as I have described in London, at least they will pay for growing, and will bloom from April to September. I saw beds of light purple Pansies in Camberwell Green last summer which would have convinced anyone who required convincing that they can be grown in towns, and grown well, too.—W. D., *Peckham*.

VEGETABLES.

EARLY VEGETABLES.

Although hot-water involves much less trouble in forwarding early crops than fermenting material, yet there is no warmth so regular and congenial for the purpose as a good bed of leaves, such as those of Oak or Chestnut, which, got together before they lose their virtues, hold heat for a considerable period. To catch them at their best they should not only be collected as soon as possible after they are shed, but when they are in a moderately dry condition, for if wet, the fermentation is either excessively violent or so imperfect as to be of little or no service, unless mixed with an equal bulk of stable manure. The two combined, if turned over a few times and thoroughly sweetened by allowing the rank steam and gases to escape, form an admirable bed for forcing Asparagus. Next to forced Asparagus,

Potatoes are considered the greatest luxury in the vegetable way, and there is no plan of obtaining these so good as growing them on a gentle hotbed, as, although warmth is required for the roots, the cooler in reason the tops can be kept the better and more satisfactory will the crop be. Heat above only produces long, attenuated haulm, and more particularly is this the case if there is at any time a deficiency of air

or sun to thicken and consolidate the growth and foliage; the latter of which, when under confinement, always comes thin and flimsy in texture. One advantage in growing early Potatoes is that the frame may be made to do double duty, and thus economise space, as, between the rows, Cauliflower or Lettuce may be sown and raised, or a crop of Radishes obtained and cleared off long before they can be got in the open, however favoured a border or position they may have. In order to get these well in advance of the Potatoes it is always advisable to soak the seeds a few hours in warm water before sowing, which accelerates its germination considerably, but when this is done, it should be well timed, so as to have the bed all ready, with a proper degree of heat in the soil, otherwise the tender germs get a chill, and instead of having handsome-shaped Radishes they are all fangs and roots.

Where frames are now in use, and it may, on that account, be desirable to defer making up hotbeds for Potatoes, they may be forwarded very much by placing them on end in boxes, filled with sifted leaf-soil, so as to just cover the crowns of the tubers, and if then stood in any warm shed or house they will form strong shoots, round which a quantity of roots will be emitted, so that each Potato may be lifted and planted with a large ball without suffering the least check if the planting is done in a careful manner. A very good way of getting a few early is to get some large pots and place two or three tubers in each, according to their size, when they may be set in any light, airy house, where they can get a little heat, and afterwards plunged in a bed of fermenting material to finish them off. The pots at starting should only be about half filled with light soil, as they do better earthed up later on when the tops get advanced and require support to keep them erect.

Seakale may be forced to any extent with a few cartloads of leaves shot in any out-of-the-way corner by digging up the roots and plunging them therein, the bulk of ours being brought on in this manner before the leaves come into use for hotbed work, and while they would otherwise be lying idle. The plan we adopt is to pack the roots tightly in rich soil in large pots, over which others of the same dimensions are inverted and slightly covered to exclude the light, when the heads come slowly on, are of large size, and of most perfect whiteness and quality. Besides forcing well in a bed of leaves, as above named, Seakale may be brought on almost anywhere if there be heat available, as there is always near chimneys or furnaces in use, or where hot-water pipes run underground before reaching the houses they are intended to warm. Such places made the most of will yield a large supply and answer equally well for Rhubarb, but as the heat so obtained is of a dry nature, the soil immediately surrounding the roots should be kept well watered to prevent them from shrivelling.

French Beans a little later on do far better planted out on hotbeds than they ever do with their roots confined to the limited area of a pot however well they may be attended to, and if a pit can be made use of with a pipe for top heat, they succeed almost as satisfactorily as when planted out in the open. The steam arising from manure and leaves, impregnated as it is with ammonia, is very conducive to the health of the plants, as it not only wards off red spider, which are generally so troublesome to Beans grown under glass, but the leaves, no doubt, absorb some of its nutritive properties, on which the roots feed likewise, when it is passing through the soil. It is a well-known fact to those who have had much to do with raising Cucumbers and Melons, that there is no place where they do so well after the turn of the year as in a hotbed frame, and many who grow them on trellises in houses prefer sowing their seed and nursing the plants on in the genial atmosphere such a situation affords. A small frame will render much good service for all purposes of this kind, and the most useful way of making it up is to have a few rough faggots at the bottom, so as to admit of driving fresh heat under by means of linings instead of having so large a body of stuff at starting. The linings can then be added to or renewed at pleasure, and a tolerably regular temperature thus kept up.

S. W.

How to Grow Good Onions. — Manure and trench the land in autumn or winter; if heavy, throw it into ridges, but if light, leave it flat. In February spread over the surface of the beds about 3 in. of thoroughly decayed manure or rich compost, including the charred refuse from the rubbish-heap; fork it lightly in, so as to mix it with the surface-soil. In March, when the surface is dry, tread all firm, rake level, and draw drills 1 in. deep and 8 in. or 9 in. apart, or more if large bulbs of Onions be required. Sow the seeds evenly and thinly; tread them in, and draw the back of the rake over all, leaving a level surface. As soon as the young plants appear, choose a fine day to stir the soil amongst them, and follow this up as often as time can be spared during the growing season. When large enough thin out to 3 in. or 4 in. apart; this should be done in showery weather, as they come up better and without disturbing the roots of those intended for the main crop. Salt in small quantities is an excellent stimulant for Onions, especially for a dry soil; soot, also, is very beneficial when applied to the land in spring, or as a top-dressing to the crop during its early growth. The season of growth of the Onion, especially when sown in spring, is short; therefore, everything should be done to prevent the crop receiving a check when the plants are young. Sprinklings of artificial manure in the majority of seasons will well repay for the outlay and labour. It is when a check comes from sudden drought, or any other cause, that Onion maggots are usually so difficult to be dealt with. If by high culture continuous growth can be secured till the bulbs ripen off naturally, the maggots will not do much injury. In August or as soon as the tops die down—and it is a good plan to assist the maturing of the bulbs by bending the tops—pull them up and lay them on a hard surface to dry, turning them over occasionally; and when thoroughly harvested, tie them in ropes or bunches and hang them in some dry, cool, well-ventilated place, as frost does not injure them. In all inferior or difficult soils, sow in August, about the second or third week, on a dry open piece of ground; keep them free from weeds during autumn, and transplant early in February on to land prepared as recommended for spring-sown Onions. In this way very fine bulbs are invariably obtained. The truth is, that Onions require a longer season of growth than can usually be had in our climate. Drought too often checks growth and dwarfs the produce, hence the advantage of sowing in autumn to give an early start. The sorts commonly sown in autumn are the various forms of Tripoli; but it is by no means necessary to confine ourselves to these kinds alone, as the Spanish, Globe, and other better-keeping kinds will do equally well if sown in autumn; and if the main sowing be made at that time, it is important for a portion of the crop to be of the best-keeping kinds.

Javanese Screw Pine as a vase plant

Snowflake Potatoes.—In a recent issue of GARDENING a correspondent ("Burns") finds that Snowflake is rather a slow growing variety. Now this is very different from not only my own experience of it, but also, I believe, diametrically opposed to its generally recognised character, viz., that of "possessing very rapid growth and early development of the young tubers." I am afraid that the cause lies somewhat in the too early planting of them. I planted mine on April 13. These were dug up for table and exhibition purposes on July 23, and a finer or handsomer crop I never turned out. I would advise our friend for the future to defer planting them till the middle or even the end of April. They will then not only be less liable to get frosted down, but will have a warmer temperature, and consequently a quicker growth, which, I need scarcely add, conduces immensely to the formation of handsome tubers.—NORTHANTS.

GLASSHOUSES & FRAMES.

THE VARIEGATED JAVANESE SCREW PINE.

(PANDANUS JAVANICUS VARIEGATUS.)

WHERE room can be afforded this is well worth cultivation. A finely grown specimen of it well furnished with its prettily variegated pendent leaves is highly attractive; but it should never be too much crowded, for if it cannot stand quite clear of other plants half its beauty is lost, a remark which also holds good in reference to all plants of a similar habit. Their greatest charm lies in their finely-arched drooping leaves, which to be seen to advantage must stand clear of everything near them. This Pandanus is very attractive even in a small state, but it is only when it acquires a size of some 4 ft. high, and as much through, that it is seen in proper character. It is of easy culture; a small healthy plant of it in, say a 6-in. pot, if potted in February or March, into a 10-in. or 12-in. pot, well drained, using good turfy loam, with the addition of one-sixth of clean sand, making the soil quite firm in potting, will make a nice half-specimen in a year. It requires a night temperature of from 65° to 70° during the growing season, and a rise of 10° in the daytime. Keep the soil moderately moist, syringe the plant in the afternoons, and keep it well elevated near the glass, in order to induce a short, compact growth; shading very little, as when much shaded it does not come so finely variegated. It is not very liable to the attacks of insects, except scale or mealy bug, both of which must be kept down by a diligent use of the sponge and camel's-hair brush. In the winter keep the soil a little drier than in summer, and maintain a night temperature not lower than 60°. Small plants may be used for table decoration, or in a larger state for vases, but they must not be kept long out of heat, or they will suffer. Suckers taken off and inserted in small pots, using half sand and loam, and keeping them moderately close, soon root, after which they should be treated as recommended for larger plants.

Ageratums in Winter.—To have these in full bloom at this time of the year may be of little moment to some, but where house room is limited, any bits of bloom at this period are highly valued. Plants which are used in the flower garden during summer, if cut well back early in September, will start a second bloom. If these are lifted into 4½-in. pots they will bloom in a greenhouse far into the winter.

Ageratum Countess of Stair has a close, compact habit, and is well suited for pot culture; moreover, it furnishes a delicate pleasing hue of colour that is far from abundant at this time of the year. Those who have plenty of house room and a gentle warmth will have no difficulty in keeping it in bloom for some time.—D.

GREENHOUSE ACACIAS.

Acacias, though very showy, are but seldom met with in small gardens.

A. Drummondi, when covered with a mass of bright yellow flowers, is one of the most telling plants we have, and is valuable either as a small plant or large specimen, flowering equally well in either state. Bushy, well-grown plants in 4-in. and 6-in. pots are very useful for decorative purposes, the habit being neat and compact, and the colour striking. When associated with such plants as Cinerarias, Cyclamens, and Azaleas it is seen at its best. This species is easily propagated from half-ripened shoots inserted in silver sand and placed in a close frame or house, covering them with a bell-glass. In March they may be potted off into a compost of fibrous loam and peat, and kept growing along during the summer in a frame, stopping them occasionally to induce a bushy formation. In September they should be thoroughly hardened by full exposure to sun and air, housing them about the commencement of October. The following season shift into 4-in. pots, placing a neat stake to each, tying the stem firmly thereto at the base, and treat them as before. They will the next year flower profusely, and may then be shifted on as required. Where large specimens are necessary for conservatory decoration this Acacia will be found very suitable, as it is not at all of a miffy nature or liable to go off, as many New Holland plants are apt to do when they arrive at specimen size.

A. pulchella is a beautiful species, and not at all difficult to grow.

A. armata is an old and well-known kind, one that will bear a deal of rough usage, but it is very liable to be attacked by scale, which must be promptly exterminated if the plants are to be kept in a healthy state.

A. lophantha is a great favourite for window decoration, its light, feathery, gracefully-disposed foliage rendering it one of the most suitable plants which we possess for that purpose. It should be grown by every one, and as it comes freely from seed, which may be obtained very cheaply, there is no reason why anyone who has the smallest amount of convenience for plant growing should not possess it. The seed should be sown early in the spring, if possible in a little gentle bottom-heat, and kept growing on during the summer months, potting so that it does not become stunted; a free quick growth is essential to secure handsome foliage. Plants suitable for window decoration may be thus obtained the first year. Where convenience for raising the seeds does not easily exist, then they may be sown in April and placed in a cold frame, placing a piece of glass on the pan. When up pot the plants off into small pots, and keep them till the following April, when they may be shifted into 4-in. pots.

By no means allow them to suffer from want of water, as they will become naked at the base, thereby much impairing their decorative value. Good fibrous loam and leaf-mould suit them very well, but they are by no means fastidious as to soil. The best plants I ever grew were potted in some very old rotten manure, but if this be used it should have been thoroughly well sweetened, and should be at least three years old. This plant is most useful when from 1 ft. to 2 ft. in height, but if sufficient space can be accorded it, it will increase in beauty as it attains larger dimensions. It is not advisable, however, to retain them after they have filled the largest-sized pot; it is better to grow a few on every year, so that those that show signs of becoming bare or stunted may be made away with. Where there is sufficient space to plant it out, it naturally assumes more handsome proportions than are to be obtained by pot culture. It is well worthy of a place in a large cool house, as, by reason of the unique disposition of its foliage, it affords a fine contrast to most other plants. I once had it planted out amongst Camellias in a lofty house, and it presented at all times a charming appearance. This species does not flower in a small state; it is, consequently, to be regarded as being valuable only as an ornamental foliaged plant. The Acacias are essentially amateurs' plants, inasmuch as they are of easy culture, and do not require so much care in a general way as many greenhouse plants do; they grow rapidly, and are by no means fastidious with respect to winter quarters. Those who would wish to grow a few of this genus should procure their plants in the autumn, choosing young, thrifty plants, if possible, in 3-in. pots. Keep them in a cool, airy house during the winter, water only when dry, and they will be in good condition for growing on in the spring.—B.

Winter-flowering climbing Abutilon (A. igneum).

Chrysanthemums and Standard Pelargoniums.—A few years ago much was written in reference to the superiority of the zonal Pelargonium over the Chrysanthemum, and *vice versâ*, for late autumn and early winter displays in the conservatory. Each plant had its admirers, but I never recollect seeing a mixture of the two recommended, a circumstance which I have often wondered at, seeing what a pleasing effect a few standard Pelargoniums make at this season judiciously dotted about amongst the Chrysanthemums. The fine scarlet blossoms of the one are seen to good advantage surrounded by the delicate blooms of the other, and that monotony which is apt to pervade a collection of Chrysanthemums is thus obviated. Any one who will take the trouble to prepare a few of the best winter-flowering zonal Pelargoniums as standards, for the purpose just indicated, will, I am sure, be amply repaid by the result.—H. H.

Shaded Walls and their Ornamentation.—Where walls are very much shaded it is often difficult to find effective coverings for them. In a place where Creepers have been planted from time to time, but only to dwindle and die, we have tried the following with good results: We placed the trellis on which the Creepers were trained 6 in. from the wall, and filled up the intervening space with Moss and soil. We commenced at the bottom with a layer of Moss, then soil in which the plants were placed, and in this way we proceeded, placing Moss and soil alternately, until the whole was finished. Among the plants Begonias occupied a prominent place; these were mixed with Ferns and Lycopods. And now in place of unsightly and unhealthy Creepers we have a beautiful wall, on which the large leaves of the Begonias have a fine effect. Among Ferns, Platyceriums are well suited for the purpose if placed near the top, where their forked overhanging fronds make a good finish. Davallias also soon overrun a wall of this kind, and mix well with the Lycopods.—W. B.

A Climbing Abutilon (A. igneum).—This is one of the best winter flowering plants we have seen for a long time. It is now in full bloom in the Royal Horticultural Gardens, Chiswick. It is trained up one of the rafters of a lean-to greenhouse, from whence its bell-shaped flowers, which are of a rich red colour veined with velvety-maroon markings, depend in a graceful manner. Its blooms and buds stand out free from the foliage, a quality of which other species of Abutilon are deficient. It will grow in any good sandy soil, and a little manure water or clear soot water applied when the plant is in full bloom are of great assistance.

The Greenhouse Jasmine (Jasminum grandiflorum).—This is one of the most fragrant and acceptable of all indoor shrubs, and one which is largely grown in all good nurseries where cut flowers for bouquets are desired. It is generally cultivated as a stove plant, but such treatment is not essential, inasmuch as we have seen vigorous specimens of it growing and blooming freely in a cool house. In a warm temperature, however, the plant keeps on growing and flowering, and is almost invaluable where choice flowers are much in request during autumn and winter. It is a plant by no means so plentiful as it deserves to be, since its fragrance and pure white flowers are quite distinct from those of any other plant with which we are familiar. It is easily propagated by means of layering, and grows luxuriantly when planted out in any deep well-drained soil, or when grown in pots of sandy loam and rotten cow manure. After blooming it requires to be pruned into shape, and it will flower all the better the next year.

Wintering Garden Plants.—In a well-known London nursery Tritonia aurea, and Commelina cœlestis are successfully preserved by being lifted in autumn, and having their roots laid in dry soil, in cold frames or sheds. The different kinds of Oxalis, too, are treated in a similar manner; and if planted in March or April they will flower all through the summer. The bulbs of Arum cornutum and A. maculatum are laid in sand in a cool shed, a way in which they keep much sounder, and are more likely to grow satisfactorily than those left in the open ground, even if protected. Many more plants of similar character would be benefited by being treated in this way, and an advantage would be gained by having the ground vacant, so that it could be thoroughly dug and manured as might be required.—S.

House and Window Gardening.

Cyclamens for the Window.—The Cyclamen is really an excellent window plant, and if some are purchased now that they are just throwing up their first blooms, they will, if kept in an ordinary sitting-room window, bloom freely all through the winter. Even gas seems to injure them but slightly, the deep coloured flowers suffering most, but if the room is large and well ventilated the injury done is but small. The soil should be kept just moist, and to produce this it is well to have the plants taken where the leaves can be carefully sponged and then gently sprinkled, but permitted to dry before returning to the window. Such a cleansing once a week will prove of the utmost value. The plants may be turned round from day to day to keep them from having only one side. It is very well to show the world outside the window the beauties of our plants, but we also want to see something of them ourselves. It is rather a curious fact that Cyclamens are rarely well grown away from the locality of London, where they are produced yearly by the hundred thousand for market. Many large establishments turn out

10,000 plants annually, the majority about fifteen months old or from seed. Formerly, the bulbs or corms were dried off regularly in the summer. It was a rule-of-thumb practice, from which eventually some growers broke away, and thus created a revolution in the culture of the Cyclamen. It is now never dried off; the roots are rarely at rest even in the case of old ones, but seedlings are kept growing on as fast as possible. The fact that it blooms all through the winter renders the Cyclamen so valuable; it is, in fact, one of the best of winter flowers. In the market good plants in 4½-in. pots are sold at from 12s. to 18s. per dozen.—A. D.

FRUIT.

HOW TO MAKE AND PLANT A VINE BORDER.

Draining.—The first consideration in making a Vine border is the drainage, for however great the care afterwards may be, good results cannot be attained if the young roots made in summer are destroyed in winter by ineffective drainage. The character of the drainage must be arranged according to the position of the Vinery. But few situations occur in which Vines derive any benefit by being allowed to run into the subsoil, so that, as a rule, it is safest and cheapest in the end to concrete the bottom, which should have a slope of 1 in. in the foot from the Vinery to the extremity of the border. If the subsoil be damp and retentive, take out the surface soil to the depth of 18 in. or 2 ft., and fill in with refuse brick or stone, covering the whole floor with 4 in. or 5 in. of concrete, and allowing it to get thoroughly dry before introducing the drainage. Run a main drain parallel with the border 10 in. below the concrete; and, to make sure of perfect drainage in case of spouts running over, lay a row of 2-in. drain tiles, at distances of 6 ft. apart, at right angles with the main drain, filling in between with refuse brick or stone to the depth of 9 in., and finishing off with finer material; over the drainage place fresh turf with the Grass side downwards.

Soil.—In making borders for Vines care should be taken to have them of a permanent character, avoiding rank manures and a too retentive soil, which destroys the active roots in winter, producing long-jointed wood, and shanking the following season. Under good treatment, Vines will continue in a healthy bearing state for a good many years. The best material for borders is a good, strong, fibrous loam, of a calcareous character, with plenty of fibre in it, taken not more than 3 in. deep from an old pasture. First mow off the Grass and stack the thin turves for a month or two previous to using them; although, if the turf be in a dry state, it may be used at once. Fibrous turf, being often difficult to procure, is, however, fortunately, not the only material in which Vines can be grown, for fair Grapes may be obtained from Vines in any good ordinary soil, mixed with a few ½-in. bones, broken brick, or lime rubbish, with rich top-dressings of manure. In forming the border it is a mistake to make it the full width at first, as a great portion of it must be unoccupied with roots for some time, while the fibre is decomposing to no purpose. Make it piecemeal, as every addition throws fresh vigour into the Vines. Get a quantity of waste bricks, according to the size of the border, and break them up similar in size to stones used for road making. I prefer broken bricks to lime rubbish, particularly in the case of early forcing, where the borders have to be kept dry during the months of July and August. The roots, coming in contact with the pieces of brick, throw out rootlets that completely envelop them, and, even if the border be dust dry, I find these rootlets quite fresh, being preserved by the moisture contained in the brick. There is no necessity for going to a great expense for materials, inasmuch as broken bricks, a few ½-in. bones, and some good fibrous loam, with perfect drainage, are all that is required. Such a mixture is always sweet and lasting. Manures of any kind should always be applied on the surface, the water from rains and otherwise conveying it to the roots by degrees, as required by the Vines, thus keeping the border sweet and healthy. The drainage being complete, let the border extend 5 ft. from the front wall, both inside and out, making, together with the arch, about 11 ft. To every five or six barrowfuls of chopped turf, add one or so of broken bricks, according to the character of the loam; beat all well down, with the back of a four-pronged fork, to the depth of 3 ft., sloping to the front, where there should be a dry wall of single bricks, to keep the materials in their place, and to induce any roots that come in contact with them to throw out laterals or rootlets, and protect them from the weather. Additions of not less than 3 ft. should be made to the border every year until it is completed. If the soil surrounding the border be of an unfavourable character, it is best to cut the roots off from it by means of a wall.

Planting.—The following are the best Vines for forcing, to cut in March, April, or May, viz., Black Hamburgh, Foster's Seedling, Madresfield Court, and Muscat of Alexandria. Muscat of Alexandria should be planted at the hottest end, and given less air than the others. Late Grapes, for use in the winter months, should consist of Muscat of Alexandria, Alicante, Lady Downes, Gros Colmar, and many other varieties might be added. In selecting Vines for planting, those that are one year old are perhaps the best in the hands of the inexperienced; and, to make sure of being free from the Phylloxera, it is best for all growers to raise their own Vines. I prefer Vines raised from eyes in spring on pieces of turf, as they are easily transplanted without interrupting the growth. When your neighbour, who possesses healthy Vines, is pruning select the best ripened short-jointed prunings with plump eyes, tie them in a bundle, label them, and lay them in the soil by the heels in a cool greenhouse until say the beginning of February. In preparing the eyes cut the shoots with a sharp knife into lengths of 2 in., the eye being in the centre; cut away the wood on the upper side within a ¼ in. from the eye in a slanting direction. Cut rather more than the number required of fibrous turves, 6 in. square and 2 in. thick. Cut a niche in the centre, and place in it the eye, covering it over with fine soil, and packing the turves closely together on slates; then give a gentle watering with tepid water, and place them on a bottom heat of from 70° to 75°, with a moist atmospheric temperature of from 60° to 62° at night, and from 70° to 75° in the daytime, with plenty of light. When started in a low temperature, the buds lose vitality, which weakens the growth. As soon as the roots begin to show themselves through the sides of the turf prepare for a shift by cutting double the number of turves you require 12 in. square and 2 in. thick, placing one on the other on separate slates, and cutting the centre out of the uppermost 6 in. square. Select the most promising young Vines, and carefully place them in the turf, which should fit exactly, cutting off first, with a sharp knife, the points of the strong roots round the edges of the turf, an operation which causes them to throw out more lateral roots and strengthens the growth of the weaker rootlets, closing the union with a little fine soil; then give a gentle watering and replace them in bottom-heat, which must be maintained. Give ventilation only when the weather is favourable, and if all goes well, they will be ready for planting out in a month or six weeks. The border being ready, a hillock, 5 in. or 6 in. higher than the intended position at which the Vines should stand, should be made against the front wall of the house, to allow for subsiding. This keeps the collar of the roots well up, and allows plenty of room for top-dressing. Vines should never be allowed to root up the stem through earthing them up. Being on separate slates, the plants may be carried and placed in their positions on the slates, slipping them from under the Vines without the least check, and filling up with the compost. Give a gentle watering, and tie each plant to a small stake, until it has reached the wires. If it be intended to grow plants beneath the Vines, they should be planted 3 ft. 6 in. apart, but if for Vines only, 2 ft. 6 in.

Large-flowered Greenhouse Jasmine (Jasminum grandiflorum).

After Treatment.—After planting, cover the borders with half-rotten stable manure to the depth of 3 in. or 4 in.; this protects the surface, and water carries down the manurial properties into the border. The Vines being planted, the chief object is to obtain the largest possible amount of well-ripened wood and roots. On these depend future productions. Keep the day temperature at from 70° or 75°, or 5° more with sunheat, and from 60° to 65° at night, paying strict attention to ventilation, and shutting up early in the afternoon. Sprinkle every part of the floor and inside border with water. Tie the leading shoots to the wires, allowing the laterals to grow freely; and if any should take the lead, pinch out the centre, so as to keep them equally balanced, allowing them to cover every inch of the roof. In proportion to the foliage which the house contains will be the number of roots in the border. When they reach the top of the house, train them down the other side, *i.e.*, if the house be span-roofed; but if a lean-to, train them on the back wall. Watering with tepid water must be regularly attended to as the Vines get into rapid growth. When the house gets well filled with foliage and the wood begins to ripen, admit air freely, and to some extent withhold moisture. To prevent red spider, mix sulphur with milk, and paint it on the hot pipes; take care to keep the foliage healthy until the wood gets brown and solid, when the ventilators may be opened to their full extent. As soon as the leaves have fallen prune at once, heading the Vines back to a foot or so below the bottom wire, as the buds at the base rarely break if the shoot be left long. When the wounds are dried up, rub a little painter's

knotting over them, young Vines being liable to bleed. Cover the outside border with litter and wooden shutters to protect the roots from rain and frost, keeping the inside cool until the time to start again has returned.

The Second Year.—In the case of late Grapes, the Vines should be allowed to break into growth without fire-heat, which they generally do about the end of April; but, if for early fruit, close the Vinery the first week in February. Wash the glass and woodwork with soft soap and water; whitewash the walls with new slaked lime mixed with a handful of sulphur; paint the wires with white lead and turpentine, or as a substitute paraffin; in fact, it is the best plan to give a coat of paint inside every year at starting time, an operation which both destroys the eggs of insects and preserves the wood. All the spent manure on the surface of the borders, both inside and out, must be carefully taken off when the Vines are started into growth, removing all the loose bricks against the front of the borders, and any roots tending downwards must be reversed. Then add 3 ft. more to the border, replace the loose bricks, and over the whole spread 3 in. of half-rotten manure, with 8 in. or 10. in. of litter, covering with wooden shutters.

Temperature.—Commence with fire-heat the last week in February, syringing the Vines three times a day, and filling the evaporating pans. Maintain a night temperature of from 45° to 50°, and in the daytime from 55° to 60°, according to the state of the weather. As the growth begins to push, the temperature may be increased, and the same attention in every way paid, as directed for the first season. At the end of April remove the shutters and litter from the outside border, only leaving the manure. Pay every attention to watering the inside border, as the Vines will grow rapidly this season, and any check from over dryness should be prevented, it being almost impossible to give a young growing Vine too much water if the border be well drained. When the leading shoots get half up the rafter, pinch out the centre and also the top of the laterals, allowing the others to grow until the leading bud breaks again, when the laterals may be pinched to three leaves. This strengthens the buds at the lower part of the Vine, which are to bear fruit next season. Allow the leader to grow to the top, where it should be stopped, thus causing the rod to thicken and the buds to swell. Allow the laterals to grow freely, as they encourage root action; if the season should be very dry, see that the outside borders receive plenty of water.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

November 22.—Planting Golden Feather Pyrethrums, Hyacinths, Anemones, and double Narcissi in flower-beds; putting a few Hyacinths in Seakale pit and plunging them amongst leaves; covering Seakale crowns, so as to be able to get at them during severe frost; manuring hand-glass Cauliflowers, putting half a barrowful to a glass; giving Cucumbers some Standen's manure; pruning old Apple trees; thinning and stopping late Cinerarias; cleaning Violets in frames; plants in flower—Mignonette, Heliotropes, Narcissi, Roman Hyacinths, Scarlet, Pink, and Scented Pelargoniums, Heaths, Coleus, Epacrises, Primulas, Bouvardias, Chrysanthemums, Tree Carnations, Fuchsias, Schizostylis, Gardenias, Cytisus, and Violets.

Nov. 23.—Sowing more pots of Fulmer's Beans; also Cucumbers on bottom-heat; planting Peach trees; moving a good-sized Apricot tree; cleaning herb beds; digging flower borders.

Nov. 24.—Sowing Radishes in orchard house; still planting Cabbage; taking up some Jerusalem Artichokes and storing them in soil to be ready in case of frost; Broccoli coming in plentifully; stubbing up useless fruit trees; pruning, tying, and painting trees in orchard house; clearing Asparagus beds; weeding beds of Lily of the Valley; starting second early Vinery at 60° at night, 65° by day with fire-heat, and 75° with sun-heat and air.

Nov. 25.—Shifting some old plants of Calceolaria aurea floribunda into 8-in. pots for spring flowering; putting batches of Asparagus and Rhubarb into heat; covering stacked Strawberry plants from frost and snow; putting some litter over Parsnips, Seakale, and Artichokes; packing some Parsnips, Carrots, Salsafy, &c., in ashes in root house, so as to get at them easily during frosty weather; examining Orchids for thrips and fly; inspecting fruit room; filling up remaining space in Seakale-bin with manure for next crop; pruning pillar Roses; beginning to prune Vines generally, also espalier Pears.

Nov. 26.—Putting Roman Narcissi in flower in 3-in. pots for stand embellishment; taking up and re-planting over-luxuriant Plum trees in order to induce fruitfulness; putting in Roses and Pinks to force; strawing Endive under walls; covering young hand-glass Cauliflowers, frost being very severe; fumigating Orchid houses for fly and thrips; cutting tops off Gladioli and putting their roots under greenhouse stage.

Nov. 27.—Taking up, dressing, and re-planting Briers; putting some small Heliotropes into early Vinery to induce them to open their buds; washing Camellias; making up hotbed for Carrots and Radishes; securing the necessary quantity of Chrysanthemums for cuttings, and seeing that those to be saved are correctly labelled.

Glasshouses.

Chrysanthemums.—Everything should be done to keep the foliage fresh and healthy; air ought to be given when the weather is at all favourable, for if there is any mildew, anything approaching a stagnant atmosphere will cause it to spread. Where Roman Hyacinths are grown in considerable quantities, these will be very useful in assisting to keep up the display of flowers in positions that are unsuitable for large plants, and successional stock of them will be found much more satisfactory for bringing on into bloom than any attempt to force the larger kinds until later in the season.

Brugmansias.—These plants are only suitable for roomy houses, and for such there are few more commanding objects when in flower. A mistake which often occurs is letting them get too large both in the head and at the root, for which there is no necessity whatever. They look best as standards on straight clean stems from 4 ft. to 5 ft. high. In order to keep them within bounds as to size, nothing more is necessary than to cut the heads close in after blooming, and instead of increasing the root-room, remove a considerable portion of the soil once a year, and replace it with fresh material. If the plants are cut in now they will occupy very little room through the winter, as they can then be set in any house or pit out of the reach of frost, just keeping the soil in a slightly moist condition.

Myrtles.—Time was when large bushes of Myrtles might be seen in almost every greenhouse, for although they will live out-of-doors in some parts of the kingdom, their leaves are not so bright looking as when they are grown under glass, particularly in the winter season, when they are of most use. Not only are their flowers pretty, and the plants, when well managed, always fresh and green in appearance, but for mixing with arrangements of cut flowers they are most serviceable; a moderate number of their green sprays may with advantage be used even in the choicest bouquets, as, besides the perfume of their leaves being agreeable, employed round the outside there is no better material for giving support to the whole. Cuttings made from the young shoots now and inserted thickly in pots filled with a mixture of sand and peat, with a little sand on the surface, well moistened, and covered with propagating glasses, and kept in a greenhouse temperature during the winter, will by that time be callused over, and if then put in a little heat will root freely. If through the spring they are kept where a little warmth can be given them they will get a start such as will enable them to make good, small, bushy plants before the autumn. Old specimens that have become at all naked and bare may be freely cut back any time, and if affected with scale or other insects they should be frequently dipped in or syringed with insecticide before they break. If placed in a greenhouse and kept somewhat warmer than ordinary, they will start into growth in good time, and though it may not be the practice with many to reduce the heads of anything of this character until nearer the time when they would naturally begin to grow, by thus treating them in the winter, where means exist of keeping them slightly warmer than they would otherwise need to be, they not only get a start that enables them to make much more growth through the summer, but the weakening influence of bleeding, that generally results when they are cut back a little time before the spring growth commences, is avoided. It also affords an opportunity for a thorough cleansing of the plants when they are at all affected with insects.

Cinerarias and Herbaceous Calceolarias.—Cinerarias intended for the latest spring-flowering, if not already placed in their blooming pots, should be so before the roots get too much matted, as, when once they get into that condition, there is less chance of the additional root room which they receive when put in their flowering pots having its full effect in inducing strength and vigour. They will bear the soil being made very rich by the addition to good ordinary turfy loam of some well rotted manure and leaf-mould, and they should be potted firmly in all cases, leaving a little more space than usual for watering. Herbaceous Calceolarias should on no account be allowed to remain in the little pots which they have so far occupied until their roots get at all matted; they will bear larger shifts than most plants. For the ordinary purposes of decoration they will, in the majority of cases, he found most useful flowered in from 6-in. to 8-in. pots; but any one wishing to have them as strong and vigorous as possible may, by keeping them shifted on as often as is permissible, grow them so as to attain a large size, and be proportionately better flowered than smaller plants. Like the Cinerarias, they enjoy the soil being made very rich with rotten manure and leaf-mould. In order to grow the above plants with anything like success they must be kept perfectly clear from green fly, for if ever allowed to get much infected with that they are certain to injure the leaves in a way that so far weakens the plants as to prevent the possibility of their flowering well, and the foliage having such an objection to severe fumigations or strong applications of Tobacco water, as soon as any of the stock becomes the least affected means should at once be taken for the destruction of the insects, examining the plants at short intervals with a view to detect them directly they make their appearance. The first batch of Cinerarias that either are now or will shortly be pushing up their bloom-stems, as also those that are later, and whose roots have got fairly hold of the soil, should be regularly supplied with manure water. There is one thing in plant cultivation always apparent when the subjects are vigorous and strong, resulting from a continued course of attentive management from their first propagation upwards; they are generally much more seriously injured by any neglect than others whose growth is of a more stunted, less free description. This is particularly the case with plants whose leaves and stems are soft in texture like those of Cinerarias, which, where really well grown, and furnished with large, stout, healthy foliage, if only once allowed to get too dry at the roots are thereby so far affected as not only to lose much in appearance, but have their flowering capabilities proportionately diminished. These remarks are made with a view to impress upon those not experienced in their culture the greater need for carefully attending to the wants of strong early propagated plants that either at the present time, or shortly will be, throwing up their flower-stems, as it often happens at this season of the year, when plants need water so much seldomer, that they quite as frequently suffer from its non-application as in dry summer weather, when the whole require it possibly every day. Especially does this occur when such things, for want of room, have to be placed on shelves over the paths and other positions not very easy of access. The same remarks apply to herbaceous Calceolarias, though these, except those propagated from cuttings, will in few cases yet have attained sufficient size to be so much liable to injury through the soil getting dry.

Shrubby Calceolarias.—Not only are these very effective when in flower, but they are much more easily managed than the herbaceous kinds. Their woody nature and the proportionately tougher character of their leaves make them less susceptible to attacks of insects, and when affected they are better able to bear fumigation, or whatever means are taken for the destruction of the animal parasites. The plants will last for years, and with fair treatment will keep getting larger, with sufficient root room, forming bushes of considerable size, very suitable for conservatory decoration. For use in this way they are better adapted than the herbaceous kinds or many other soft-wooded subjects, as they will bear when in bloom placing in positions where there is less light, such as would make the softer growing kinds unsightly in a very short time. Plants that were cut back after flowering, part of the soil removed, and repotted, something in the way that large-flowered Pelargoniums are treated, but with less destruction of their roots, should now be moved to the pots wherein they are intended to bloom. The

yellow flowered kinds, particularly the old sort, aurea floribunda, are especially adapted for using in this way, as if kept a little warm through the winter, say from 40° to 46° in the night, they will flower early, and with sufficient root room and regular liquid feeding will keep producing flowers in succession for a great portion of the summer.

Lilies.—Those that flowered the latest should now receive whatever attention they require in repotting or renewal of the surface soil; where there are not more bulbs in the pots than will have sufficient room for another season, the latter will suffice. But with all it is well at the same time to see that the drainage is efficient, for, standing about as these plants usually are a good portion of the summer on the ground or other moist surfaces, worms are very apt to get into the pots, in which case the drainage is almost certain to get more or less clogged up. From this time until spring, when the young shoots have appeared above the surface, the soil should be kept in not more than a slightly moist condition, that is, just so as to permit of the root growth that with most kinds will after this time very shortly commence. There are few finer subjects for a large conservatory than L. giganteum, although the plant in favourable situations will live and thrive with a little protection through the winter; yet it is seldom so fine as when under pot culture. Plants of this species now in cold frames or pits should have plenty of air on all favourable occasions, and, if they are expected to bloom next year, should not be allowed to suffer for want of root room, though where there is not danger of their being thus affected, it is not advisable to place them in the flowering pots until later on.

Flower Garden.

Carnations and Picotees.—The plants that are well rooted will be quite safe in cold frames. When thaw comes look carefully over all choice sorts, remove any dead leaves, and just stirring the surface soil in the pots if it is caked. Those who have planted out their beds will now see the value of a surface dressing of dry rotten manure. After the frost is over examine all the plants carefully, and gently press them into the ground with the fingers of both hands.

Gladioli.—Those who have not yet stored their bulbs should lose no time in doing so; cut the stem over close to the top of the corm or bulbs. They must be dried in the same way as Dahlia tubers before storing them; each sort may be put separately in a bag, and the whole can be stored away in a box until February, when it will be necessary to overhaul them to see if any are injured by decay, and those that are starting into growth must either be potted or planted in a warm sheltered border in order to obtain an early bloom.

Phloxes and other herbaceous plants in pots will be quite safe in cold frames if the weather is severe; if previous instructions have been followed the soil in the pots will not be very moist, and no water should be applied during frost.

Vegetables.

The long evenings will now afford abundant leisure for devising plans for future cropping, and also for summing up the results of the past season's operations, such as noting the varieties of vegetables that have been most satisfactory, or, indeed, anything by which we are likely to profit in future. By thus mentally arranging our work in something like methodical style, we save ourselves a large amount of physical labour and embarrassment, to which haphazard cultivators must of necessity be subjected. If the hints given in former notes have been acted on, all root crops will now be securely stored, and when bad weather impedes labour in the open air such root stores can be overhauled. Potatoes will need frequent examination. Examine Cauliflowers and early Broccoli daily, for the purpose of either cutting or sheltering from frost all that are ready for use. Cauliflower plants under handlights will now be the better for having the lights put over them at night, for though they may not seem hurt for some time, a few degrees of frost cripples or stunts them, and this leads to "buttoning." Those plants that were pricked out at the foot of south walls will now require shelter in order to ensure their safety, and the same remark is applicable to Lettuces and Endive. Plants of these that are fully grown are best lifted with balls of earth and planted in orchard houses, cold pits, or frames. Besides affording protection and arranging details as regards forcing Asparagus, Seakale, and Rhubarb, there is little else of a routine character that now demands attention, and therefore the present will be a good time to undertake extra work, such as making new walks, opening or putting in new drains, planting Box edgings, levelling, grubbing, trenching, and, indeed, any work for which time cannot be afforded during the busy season.

Fruit.

Vines.—The present month is generally a most anxious one for those having Grapes still hanging on the Vines, for, unless they have been well ripened, the probability is that cracking and damping off will be prevalent, and though it may be impossible to entirely stop such occurrences, much may be done to check them by daily removing all bad berries, and by keeping the atmosphere dry and warm, and removing all surplus shoots that have hitherto been left as root producers. Good keeping can only be secured by thorough and early ripeness, and any who are troubled because their Grapes are keeping badly would do well to in future start their Vines earlier. Some are prevented from doing this under a belief that if ripe too early the Grapes would shrivel before they were required for use, but with late Grapes this is never the case; but in early houses with Grapes ripe in May or June it would be marvellous if they did not shrivel, considering both the varieties of Grapes that are grown for early use and the weather at that season. Prune Vines in mid-season houses as soon as the Grapes are cut, and where there are but few remaining, cut and bottle them, in order that the Vines may receive the treatment most conductive to rest, viz., plenty of ventilation.

Notes on Lilium auratum out-of-doors.—My bulbs of this Lily were planted singly in the open ground in the spring of 1867 in Rose beds, in a light sandy loam, the subsoil being gravelly. The Rose beds are from 2 ft. to 2 ft. 6 in. wide. At no time did they receive any liquid or artificial manure; the beds were simply mulched with well-rotted farmyard manure in the month of November, this being the only protection afforded them. Out of all the bulbs planted, only five have died up to the present time. The bulbs have increased remarkably, as this past season from six to ten stalks were common enough, and in quantity and quality the blooms were most remarkable. The greatest height attained was 7 ft.; only a very few reached that figure, one stem measuring 4 ft. 9 in. high and 6 in. across the top. The stem bore 242 blooms; this was a single stem resembling in shape a Cockscomb. The appearance of the head when in flower was like a huge Hyacinth; a clump of six stems bore 166 blooms, another with four stems 75 blooms; three stems 62 blooms; one stem 6 ft. high 59 blooms; one 7 ft. 50 blooms; one 4 ft. 46 blooms. Some heads of flower lasted in perfection up till the middle of October. Lilium auratum is the only variety at present under cultivation here, at least out-of-doors. The situation where grown is only moderately sheltered, being most exposed to the west. Admirers of this beautiful Lily should find encouragement in the fact that at this place the winter of '78 and '79 had not the least injurious effect on my bulbs.—S. M., *Fortbreda, Belfast, Co. Down, Ireland.*

French Marigolds in Autumn.—I do not think that the merits of these free-growing, profuse-flowering, and continuous-blooming annuals have received the appreciation which is their due at the hands of the owners of gardens generally. Were it better known how fresh and bright they remain throughout the autumn months, presenting quite a gay appearance when the generality of tender plants have had their beauty washed away, they would undoubtedly be held in much higher esteem. Many turn from the Marigold with something like contempt, holding it as a coarse and weed-like subject. This flower has, however, been so much improved of late years, that it now forms an elegant plant for any garden, and will not fail to charm by its finely-cut, rich green foliage and bright, exquisitely-formed flowers. I recommend these annual Marigolds to the attention of flower lovers generally, as, owing to the neat, compact habit which distinguishes the best strains, they are suitable for the smallest of gardens.—John Cornhill.

Polygonum fagopyrum.—I do not find the above plant "an annual" in any seedsman's catalogue, which has surprised me very much, nor do I ever remember to have seen it catalogued. In spring, a neighbour of mine, a French gentleman, brought over a few young plants and gave one to me, which I put in a 7-in. pot and placed in the greenhouse, where it grew rapidly, and flowered in September. He put his in the open ground, where they did pretty well, but did not form any seeds, whereas mine did. There was also a difference in the beauty of the leaves; in the greenhouse they were glossy and large, his were dull and yellow, probably from the weather. The plant forms a single very strong cane, exactly like a Bamboo, except at each joint there is a singular collar composed of a leaf, and from each joint comes one leaf. When it attains a height of about 5 ft. it throws out five or six stems, each with three or four tassels composed of small crimson flowers, and each tassel being about 3 in. in length. The whole plant is perfectly straight, and therefore occupies very little room; it requires no support, the cane being like a small walking cane. The plant turned out the most interesting one I had, and was greatly admired. Groups of three or four together would show admirably in Kensington Gardens or any public park. I cannot say anything as to its improvement, but should imagine that a simple affair; it was potted in the usual potting soil, and stood waterings with guano water, but on a future occasion I shall put it in a larger pot.—W. T., *Dorset.*

Polygonum fagopyrum.

Adam's-needles and Stonecrops.—Having on my lawn a bed of Yuccas which could not be planted very near together, I was anxious to fill up between with a suitable plant, but could not for some time decide what this should be. Ordinary bedding plants would be out of the question, and although the variegated Ivies have been recommended for this purpose, I objected to them, as taking too much out of the soil. I, therefore, at the end of April took off some shoots from my old plants of Sedum fabarium, which were then about 4 in. in length, and studded them all over the bed about 6 in. apart. The combination has been much admired all the season, and when the Sedum was in bloom it formed a most distinct and handsome bed.—Berks.

Gladioli Wintered Out-of-doors.—It has been my practice for some years past to leave our Gladioli in the ground all the winter, taking them up once in three or four years and transplanting them. When the tops are dead I cut them off near the ground and give a good

coating of half-decayed manure and leaves before frost sets in ; this, I find, to be sufficient protection, the soil here being a light, sharp loam. I have sometimes had the early kinds damaged by late spring frosts. It is, I think, incorrect to say that bulbs taken up and dried till spring do not produce as fine spikes as those left in the ground. I know a very extensive grower of Gladioli whose bulbs are taken up every year, dried, cleaned, and labelled, and yet at every exhibition at which they have been shown they have carried off most of the prizes for years past —W. D., *Maidstone.*

Propagating Wallflowers.—I have lately put in some cuttings of selected dark and yellow Wallflowers. If put into some good light sandy soil, as one would those of Pansies and such like, they strike quickly and make good plants for blooming in spring. Amongst Wallflowers it will always be found that some are finer than others—of a dwarf bushy growth, and with large, well-formed flowers of good quality. The best strain of seed may not ensure kinds so good as these, therefore the expediency of using cuttings. The pretty dwarf Belvoir Castle Yellow and the double kinds are best kept propagated in this way in order to preserve the correct type.—D.

Dahlias.—While the weather is still favourable the ground should be prepared for next year. Even if the soil is rich it will not do to trust to only digging it over. It will be necessary to trench it 2 ft. deep or more, working in to it plenty of good manure. The best for this purpose is to obtain, if possible, equal quantities from the cow-sheds and stables ; throw the two up into a heap, mixing them well ; turn them over twice at intervals of a week, and in a month it is ready for use. A word here on trenching : Workmen may frequently be seen trenching a piece of ground that has been trodden hard ; they throw the lumps of soil just as they move them into the bottom of the trench. Where the soil is heavy this is very bad management, and such a loose style of trenching is to be depreciated under any circumstances. Choose a fine day, when the soil is rather dry, to fork the surface over, breaking up the lumps well. In a week or ten days after this has been done the ground may be trenched. Thus treated, a loose dry soil will be placed in the bottom instead of hard lumps, which, even if they are broken up as thrown in, have not been submitted to the meliorating effects of the atmosphere.

Felicia capensis.—This plant does not seem to be much known, or if known, is not appreciated, for out of some eight or ten lists of plants, I only find a Felicia in one, and this variety is called angustifolia, and described as a charming Aster from Australia. Now, my experience of capensis, entitles it to a similar commendation, for, having bought a small plant for 2d. in the summer of 1879, it continued to give its pretty blue and yellow flowers in a cool and shady greenhouse nearly up to Christmas ; it then gave a good quantity of bloom in the spring, and, having enjoyed the summer out-of-doors, is now full of bloom and bud again.—Bath.

Virginian Poke (Phytolacca decandra).—This is an exceedingly ornamental plant, and very suitable for the back of the herbaceous border, or for growing in spare open spaces amongst shrubs. It has been a striking object with us in the latter position for several years past, and has stood the severity of the winters with only slight protection in the form of a little mulching thrown over the roots. The plant is herbaceous, and has immense fleshy roots that penetrate deeply into the earth in search of food, thus rendering it independent of the weather, as regards moisture, and of easy cultivation. Early in spring it sends up from its crown several stout shoots that soon run to the height of 4 ft. or 5 ft., when they divide into numerous branches. These send forth numerous bunches of flower, greatly resembling those of the Currant, and when these are set and ripe the plant has a very striking appearance, on account of their great profusion and rich colour. The berries, which are of a bluish-black colour, are about the size of a Pea, but are rugged and furrowed, and generally contain ten or twelve seeds. These should be sown early in the spring in light soil, and when up and large enough to handle may be at once transferred to the positions intended for them. Should the soil be at all rich, they must be allowed plenty of room, or they will soon overgrow anything that may be standing near. Although the plant will not attain so large a size in poor soil, it will be found to fruit more freely. Grown as a pot plant, it is valuable for winter decoration in large conservatories. The juice of the berries is of a rich purple colour, and the Portuguese have the credit of using it to give a high colour to their port wine.—J. S.

The Catalpa one of the best trees for towns. (See next page)

Trailing Varieties of Tropæolum Lobbianum. — Trailing Tropæolums until lately have been in beautiful bloom, and the plants are in luxuriant growth. This glorious autumn has prolonged many tender plants beyond their usual term of existence, for it is seldom that such as Tropæolums, Balsams, &c., are in bloom at the end of October. The trailing Tropæolums, from the luxuriant growth they make, are admirably adapted for covering up bare spots that are not uncommon in gardens. In large shrubberies, where the shrubs have during the summer and autumn a bald, flowerless appearance, these trailing Tropæolums answer admirably to light them up here and there, thrusting up their gay blossoms of scarlet, yellow, or maroon amongst the leaves. As soon as touched by frost they should be speedily cleared away, and any unsightliness occasioned by their decay at once removed. Seeds scattered in the spring give stronger plants than those turned out from pots, and produce better results.—M.

Indian Shot Plants (Cannas) **Out-of-doors.**—No person visiting the parks and gardens of Paris can help being struck with the prominent part these fine plants occupy in the laying-out of the flower-beds and borders in summer. They are most frequently grown in masses in round or oval beds, the taller specimens being put in the centre and the smaller near the edge. The leaves of the Canna are generally crimson or green, the former bearing bright scarlet flowers somewhat like a small Lily, and the latter handsome spikes of yellow blossoms. They look extremely well planted alternately in rows of red and green, and then when not in bloom they always appear gay and attractive. For a background in a ribbon border nothing can be better, but the foliage of some of the species grows very erect, and therefore the drooping kinds are preferable, being much more graceful. The Canna is valuable both as an indoor and outdoor plant, and should be more extensively grown for this reason than we generally see it. It is easily raised from seed in the spring, and can be wintered with so little trouble when left in the ground and covered with ashes, that it ranks amongst the best of our garden foliaged plants.—W. A. G.

The Large-leaved Saxifrages as Carpet Plants.—These with their fine glossy leaves form an admirable carpet of the larger sorts under thin trees and on banks ; even tall hardy flowers might be allowed at times to spring from them. The effect of the foliage when seen in broad sheets in autumn is very fine ; and where the plants flower well on warm soils, the rosy blooms in spring are charming. —V.

Wood Sorrels.—Where autumn-flowering plants are needed the three pretty Wood Sorrels, Oxalis Deppei, Bowiei, and elegans, ought to be planted. They are all still in full bloom, and would go on till Christmas if the frost would let them.—H. H.

THE SHRUBBERY.

WHERE AND HOW TO PLANT TREES.

This is a large subject, but as we are now at that season of the year when planting is done, some suggestions may not be out of place.

There is a general error in planting, and especially in the case of suburban villa residences, namely, that of placing the subjects too close to the dwelling-house. Many suburban residences are literally hidden by trees, render the interior gloomy in the extreme in dull, dark weather, besides keeping the houses damp. In an infant state the trees have a pleasing appearance, but a few years' growth will cause them to cast a gloom over the apartments and keep off a free circulation of air. A few years ago it was the prevailing fashion to plant Conifers, and they were placed in quite small forecourt gardens, and soon filled up the space and darkened the house.

The plants which stand nearest to the dwelling should be of a dwarf kind, and as far as possible of an ornamental character. There is a large collection to select from, and planters cannot plead excuse for planting incongruous subjects. The trees should be selected as far as possible to correspond with the style of building. The villa shows best when surrounded by light, ornamental trees, such as the Birch, Acacia, Sumach, Laburnum, Thorn, &c., and a clump of Poplars may sometimes be introduced, so as to break the line with good effect. The cottage may have more rustic trees, while to the castle belong the Oak, Elm, Beech, Pine, &c. The mansion admits of all at their proper distance and in suitable situations.

One of the most important things in planting is to attend particularly to the shades of green, especially where the trees lie in the line of sight from the house or lawn. Flowers, which Pliny calls the joys of the trees, continue but for

a short period in comparison to the duration of foliage, therefore, charming and entrancing natural pictures should be formed by judiciously contrasting the shades of green. Even the effect of perspective may be considerably increased by the proper arrangement of lines. Trees whose leaves are of a gray or bluish tint, when seen over or between shrubs of a yellow or bright green, seem to be thrown into the distance. Trees with small and tremulous leaves should wave over or before those of broad or fixed foliage. The light and elegant Acacia has a more beautiful effect when its branches float over the firm and dark Holly or Bay tree. In some situations the bare trunks of trees may be shown; in some they should be concealed by evergreens and creepers. Vine-like creepers can be utilised to furnish these, and form natural festoons where the extent of ground will allow of wilderness scenery. In all situations Nature should be assisted, but never deformed by clipping, for ingenuity ought to be employed to disguise art, not to expose it.

The individual beauty and graceful outline of plants cannot be displayed when they are too much crowded, as they are then in danger of being drawn up into unnatural shapes; indeed, this is a common fault in arboreal gardening; therefore the oftener open spaces can be admitted, the more fully will the shrubs exhibit themselves to advantage, and the more cheerful will be the walks winding among plantations of this character, for walks become insipid and gloomy when confined for any distance. When the wind and its possible effect on trees or on the plain need to be considered by the planter, it is necessary to take care so to arrange the position of the trees that only those gales which are most congenial to the growth of particular plants should be allowed access to them.

The undulating appearance of a plantation or piece of landscape will be considerably attested by a gradual progression from the lowest shrub to the highest tree, and, again, from the highest to the lowest. But as many shrubs will not flourish under certain trees, their respective situations demand consideration. These shrubs may, indeed, exist under such favourable circumstances, but their unhealthy appearance will never be pleasing. Where the shade of any tree is too powerful for Laurel to thrive, Ivy may be planted with advantage if it is desirable to cover the ground with evergreen. Indeed, we can scarcely overrate the value of Ivy as a subject for carpeting spaces under large trees, like the Cedar of Lebanon, where Grass will not grow. In proportion as the shrubbery or plantation recedes from the dwelling it should become more rural in its character, more especially if the residence be in the cottage style. Here climbers and such plants as require support from others can be introduced with advantage. The most delightful groups which charm the eye in a pleasure ground are generally those where Nature, freeing herself from the shackles of art, depends only on her own assistance for support. Her most delightful beauty is chiefly to be seen there where her various creations combine spontaneously and without restraint.

The means by which climbers and such plants raise themselves up, so to speak, so as to offer their flowers to the sun, are as various as they are curious, and they seldom blossom whilst trailing on the ground. The Ivy, Bignonia, Ampelopsis, &c., ascend by the help of little fibres, which fix themselves to the bark of trees or crevices in walls so tightly, as to render their disengagement a difficult thing to be accomplished without injury to the trunk or building they are attached to. The Honeysuckle, like the Hop, twines itself spirally around the trunks or branches of trees, and often clasps them so closely and tightly as to make an impression on the hardest timber. Others, as the Vine, Passion-flower, &c., rear themselves by means of corkscrew tendrils, which holds so fast, that the strongest winds seldom disunite them from their support. Some plants climb by means of a hook on their leaf-stalks, or have a kind of vegetable hand given them, by which they are assisted in mounting, as the Pea and several others. But this is something of a digression, though related to the subject. The sombre, gloomy walks formed by lines or hedges of Yew, Cypress, Holly, &c., should lead to the spot from which there is the most beautiful prospect, and to the gay parterre where Flora has diffused her flowery beauties, as a contrast of this character, particularly when it breaks suddenly upon the view, adds greatly to the cheerfulness of the terminating view.

Bad taste is seldom more conspicuous than when we see trees or plants marshalled in regular order, and at equal distances, like beaux and belles standing up for a quadrille or country dance. Where the situation will permit, and it is desirable to introduce patches of colour, four or six Lilacs, or Guelder Roses, or Thorns, or Laburnums, &c., should be grouped in one place, so as to give effect in various parts by means of such masses of colour. The Guelder Rose should appear as if escaping from the dark bosom of Evergreens, and not a plant should be set in the ground without the design of adding harmony to the whole. A shrubbery should be planted as a court dress or a stage costume is ornamented—for general effect, and not merely for particular and partial inspection. Boldness of design, which seems to be more the offspring of Nature and chance than of art and study, should be attempted, but though boldness is what the planter should aspire to, all harshness or too great abruptness must be avoided by a judicious mixture of plants whose colours will blend easily into one another.

The most beautiful shrubs should occupy the most conspicuous and prominent places. For instance, a projecting part of the plantation should be reserved for the fine, high-coloured Rhododendrons, or clumps of R. ponticum, American Azaleas, Kalmia latifolia, and other bog plants. Here, it should be observed, that there is a necessity for proper soil being prepared for these American plants, as they are likely to decay if not placed in earth congenial to their nature. With these can be associated some of the fine hardy kinds of Heath, as the same soil suits both. With respect to evergreens, considerable judgment is required, in order to relieve their uniform appearance during winter. This may be done by a skilful arrangement of different kinds and those with variegated leaves and ornamental growth, or such as retain their brilliant berries during the winter months. However, a well planted shrubbery depends not so much for the beauty, on the expense, or rarity of the plants it contains, as on the selection of trees and shrubs which succeed each other in blooming throughout the year, or whose various coloured fruits grace them for the longest duration of time.

R. D.

Old Judas Tree in a French garden

The Catalpa.—This is one of the best of ornamental trees, so far as foliage is concerned, and one that not unfrequently produces conspicuous panicles of white lilac-dotted flowers after seasons sufficiently warm and dry to ripen its somewhat luxuriant and succulent growth. It is a a native of China and Japan, and grows rapidly on warm soils in sheltered situations. It is one of the best of all trees for town gardens, growing well and flowering like a tree Gloxinia in the heart of London. The Japanese employ the wood in cabinet work and in the manufacture of fancy articles, but it is only as an ornamental tree that it is of value in English gardens. In the Middle Temple Gardens there is a singular old specimen of it, which has evidently at one time been of large size, but it is now much reduced and time worn. Another example of it, fully 30 ft. in height, used to grow in the arboretum of the Royal Horticultural Society at Chiswick, where it bloomed well every year. It is rather a curious fact that the honey or nectar secreted by the flowers of this tree is poisonous. A golden-leaved variety of it, called aurea, has been often used in Battersea Park as a sub-tropical plant, and when contrasted with the purple-flowered Clematis Jackmani in one of the beds near the rockery, it had a fine appearance. For flower garden purposes it should be cut back every spring, so as to induce it to throw up vigorous shoots and produce large leaves.

The Judas Tree.—This, which is supposed to be the kind of tree on which Judas hanged himself, ranks amongst the best of flowering trees, but when old it is not much valued for beauty of form. The annexed engraving shows an old specimen of it that has always seemed to us remarkable from the point of view of form alone. It is, of course, when in full flower, an object of great beauty. The Judas Tree is one of the most neglected in modern planting, though there are good specimens of it to be seen here and there in old gardens. The one which we figure grows in front of one of the buildings in the Garden of Plants. The botanical name of the Judas Tree is Cercis Siliquastrum. Its flowers, which are purple, are produced in May, both from the young twigs and the old wood, before the leaves appear. The flowers are succeeded by thin seed-pods 6 in. long, which remain on the tree throughout the year. Seed seldom ripens in this country, and propagation is effected by seed procured from foreign sources or from layers and cuttings of the young branches.

Weeping Trees.—The association of the common Weeping Willow with water leads people to think that it will not succeed elsewhere; but there are few spots, even away from water, in which it will not thrive if the soil be deep. I have seen really grand specimens of it

growing on lawns. Scarcely less beautiful is the Weeping Birch; for, although its spray is not so long as that of the Willow, yet, owing to the tree being more lofty, it is nearly equally effective. Not so graceful, perhaps, as either of these, but a better arbour tree, is the Weeping Ash. Owing to its extreme pendulous habit, it is necessary that it should be worked on very tall stocks, as if height is not secured at first, it cannot be obtained afterwards. The Weeping Ash should be planted in quiet, secluded spots, where, when fully grown, it may form a pleasant retreat during sunny days. It will be found that a tree, with a stem considerably bent or inclined at the top, will form the most convenient arbour tree, as the position of the stem will then be at one side, instead of in the centre.—A.

ROSES.

Tea-scented Roses.—Tea Roses may be budded on the Brier as successfully as Perpetuals. Some are, however, too tender for outdoor culture, but we have many varieties raised from seed of Gloire de Dijon which are quite as hardy as the Hybrid Perpetuals. Strong-growing sorts must be selected for standards, but the more moderate growers may be worked on Briers from 6 in. to 2 ft. above the ground. These may be potted and placed in a pit or cold frame during the winter. Tea Roses generally grow and bloom so freely that the sap is nearly always in motion, and it is partly on this account that they get injured by frost; they grow so freely, particularly in the autumn, that much of the wood that is made does not get ripened. Various plans have therefore been tried to stop their growth in autumn and winter. One consists in cutting the roots and lifting the plants with a strong garden fork as much as will be sufficient to stop the root action; but undoubtedly the best plan is to nip out the tops of all growing shoots in November, and at the same time to cut off every Rose and bud found upon the tree—operations which induce it to rest, and which cause much of the wood to ripen, and in that way withstand the effects of frost. It is even good practice to nip out the tops of Hybrid Perpetuals which are found to be growing vigorously in November. All dwarf Tea Roses are best taken up this month, potted, and placed under glass in a pit or cold frame. In May they may be planted out again. The following make good standards, and need no protection, being quite as hardy as most of the Perpetuals, viz.: Cheshunt Hybrid, Belle Lyonnaise, Adrienne Christophle, Gloire de Dijon, Comtesse Ouvaroff, Madame Emile Dupuy, Madame Levet, Madame Ducher, La Tour Bertrand, Triomphe de Guillot Fils. The following Noisettes have been proved to be perfectly hardy, viz.: Reine des Massiffs, Bouquet d'Or, Madame Caroline Kuster. As half-standards the following can be recommended, but they will want a little protection, viz.: Comte de Paris, Safrano, Abricoté, Madame Villermoz, Madame Berard, Souvenir d'un Ami, Devoniensis, Madame Falcot, and the fine new yellow Rose, Perle des Jardins.—H. T.

Pruning Roses.—The usual season for pruning Roses being near at hand, it is well to form some definite plan as to the system which shall be adopted. Where the object aimed at is a large display of bloom, I find that long shoots "pegged down" are preferable to close spur pruning. Raised banks for shutting out unsightly objects look remarkably well clothed with Roses in this way; and for a background, standards pruned a similar manner, with t eir long shoots brought down in the form of an umbrella, thereby concealing the bare stems, have a fine effect. Such varieties as Maréchal Niel, Gloire de Dijon, and Souvenir de la Malmaison, treated in this way, answer admirably, and are, indeed, more continuous bloomers than many of the so-called Perpetuals. That beautiful summer Rose, Charles Lawson, is, in its season, a really splendid object. After the beds are pruned and manured, we usually peg down the shoots with a quantity of stout pegs, varying from 18 in. to 24 in. in length, selected when preparing Pea sticks, and if good Ash or Hazel, they will last two or three seasons, and have a neat appearance.—G., *Henham.*

Correction.—"Note on Planting Fruit Trees," p. 424.—Wall trees should be so placed that the base of the stem may be about 6 in. from the wall (not 16 in.).—Ombu.

To the Trade.—Nurserymen and seedsmen are requested to forward copies of their catalogues to the editor of Gardening as soon as they are published. Office: 37, Southampton Street, Covent Garden, London, W.C.

ANSWERS TO QUERIES.

3576.—**Pentstemons, Auriculas, and Polyanthus.**—Six good Pentstemons are—A. Laing, deep rose, white throat; Meteor, bright rose; Atro-cœrulea, purplish-violet; Helvetia, white, shaded lilac; Louis Kien, crimson-scarlet; and Stanstead Rival, bright crimson. This will be found to be a fine selection, probably as good as can be had. It must, however, be understood that the Pentstemon reproduces itself freely from seed, and seed saved from a first-class strain will probably give plants that will produce as fine blooms as any good named kinds. Six good Alpine Auriculas are—King of the Belgians, Selina, Diadem, John Ball, Evening Star, and Prima Donna. With the exception of Diadem, raised by Mr. Gorton, of Manchester, all the rest are raised by Mr. Turner, of Slough, and all may be got from him. Six good Polyanthus, of the Gold-laced section, which is the old florists' section, are—Buck's George IV., Lancer, Exile, Cheshire Favourite, President, and Early Lincoln. These are as good as can be found, and are always placed in the front ranks at exhibitions. Pentstemons are about 12s. per doz. for good kinds. Auriculas are more costly; the selected six would perhaps be priced at from 2s. 6d. to 3s. 6d. each, whilst the Polyanthus could hardly be obtained for less. These latter are very slow propagators, and strong plants are not freely parted with. It is necessary that they should be obtained from some bonâfide grower, as there are not a few wretched sorts in commerce under these names that are in no way equal in refinement and beauty. Few classes of florists' flowers give such indifferent results from seed as does the Gold-laced Polyanthus. It is just possible that 10,000 seedlings of a first-rate strain would not give one really good flower. Many of the best kinds were raised twenty, thirty, or forty years ago, and cannot be beaten. There is a fine field open to the amateur florist here.—A. D.

3569.—**Woolly Aphis on Auriculas.**—There are various methods of getting rid of the woolly aphis on the roots of the Auricula, and the one we found most effective when suffering from a similar difficulty was to put a wineglass of paraffin into a gallon of water, stir it well to mix the oil with the water, and then to knock the plants with balls of soil entire from the pots, dipping them into the solution, giving them a little motion to get all the insects and the outer surface of the ball in contact with it, and then setting them close together in shallow boxes to allow the balls to dry off a little before repotting. The old pots should be well washed in strong soda-water, or new ones be used in their places. If this does not answer the plants must be shaken out and the roots washed clean. We think with you, as with us, the dipping will prove quite effectual.

3575.—**Violets not Flowering.**—There can be little doubt but that sometimes Violets will become blind, as Strawberries will, and fail to produce bloom. The only remedy in both cases is to get rid of the old stocks and obtain other plants from stocks that are true. The Violet naturally produces seed pods or female flowers in the summer, but these are entirely dissimilar from the blossoms that yield such delicious perfume in the spring. Charred garden refuse is strongly recommended for Violets, and it may prove useful in the present case if either applied to old plants as a top dressing, or applied to other soil where a new bed is made. This bloom blindness is an unusual feature, and must be the result either of the stock or of the soil. All through the Middlesex market gardens Violets are blooming freely now.—A. D.

3583.—**Trees and Plants for Boggy Soil.**—The Liquidambar or Sweet Gum tree would probably thrive on the highest, most distant spot from the river, as would also many other trees and shrubs, including the Bird Cherry, Dogwoods, Taxodium distichum or Deciduous Cypress, and Rhododendrons. There are also many beautiful things among the Maples and Poplars which will thrive in moist situations—notably the Eagle's-claw, Maple and the variegated Acer Negundo, the scarlet Maple, the white Poplar, and Canadensis Nova. Among flowering plants a very extensive list might be made out. Round the margins of the water good situations would be found for the strong growing Grasses, such as the Carex family, the Pampas Grass, and some of the Bamboos, including the common one, Arundo donax. The New Zealand Flax (Phormium tenax) would be quite at home, as would also many of the Spiræas or Meadow Sweets, and Lythrum roseum superbum and Salicaria. The hardy Lobelias, such as syphilitica, delight in moisture; and then there are the Epilobiums or Willow Weeds, the Trilliums or Wood Lilies; and as select choice plants, the hardy Cypripediums should have a place, and a few of the Japan Iris might be tried.

3581.—**Soil for Plants.**—The best substitute for peat is leaf-mould thoroughly decomposed, with crushed charcoal to keep it open. Sand is of use only for its mechanical effect, and because it blends more perfectly with the soil than any other agent will do. River or pit sand or road drift may be obtained nearly everywhere; sea sand, by reason of its containing salt, should not be used for delicate rooted plants till the salt has been removed by frequent washings. Loam and leaf-mould of good quality may be worked in, varying proportions to suit nearly all plants.

3566.—**Brussels Sprouts Seed.**—Instead of digging up the stems, as would be requisite when the produce was gathered in the ordinary course, leave them to flower, and in due course seeds will be produced. Take care no other member of the Brassica family are in flower at the same time very near, or a cross may be effected, and the goodness of the strain be injured.

3586.—**Insects in Mushroom Bed.**—Visit the Mushroom house at night with a candle; you will soon ascertain what eats the Mushrooms, and may take your measures accordingly. If woodlice are present, trap them by placing wisps of hay in empty 6-in. pots inverted or laid on their sides. Occasionally empty the insects out into boiling water. Pour boiling water round the outsides of the bed close to the wall; both the woodlice and the snails will retire there when not feeding and may be destroyed. To trap the snails lay down small heaps of brewers' grains or bran, or bits of orange peel laid hollow side downwards will attract them.—E. H.

3648.—**Treatment of Deutzias.**—It is not stated whether the Deutzia is in a pot or in the ground. In either case the roots are probably earth-bound; 3 in. or 4 in. of the top soil may be carefully removed, and replaced by any suitable compost. The lower depth of soil may previously have been stirred and loosened, and the drainage attended to.

3649.—**Water Melons.**—In India Water Melons are grown to a large size in the sandy beds of certain rivers in the hot weather when no freshets are expected. A hole is scooped out and filled with manure and loam; in it the young plants are set. The water is close to the surface, and the hot sun draws it up to the roots. The plant in this way revels in the sun, and the Melons seem to be growing, as if by magic, in a dry sandy waste. Acres are grown in this way about Seringapatam.

3653.—**Dried Lavender.**—Mitcham and thereaway is the home of Lavender. J. Field, Medical Hall, Marine Parade, Brighton, supplied me with excellent dried Lavender at a moderate price.—M. P.

3660.—**Plants for Aquarium.**—An aquarium, 3 ft. long and say 1½ ft. wide, is best made of slate frame, with one part dark where the fish can go into retirement. They should have rockwork studded about, among which they can amuse themselves by playing at hide and seek. Vallisneria is one of the best plants to grow. The bottom should be covered with clean gravelly pebbles. A tin tray containing damp sand to grow small Ferns, or to keep filled with cut flowers, &c., looks well, and the top of the open gauze cover may be similarly decorated.

3571.—**Grass under Trees.**—The best thing "G. J." can do is to write to Messrs. Sutton or Messrs. Carter. State the nature of the soil and some approximation to the density of the shade, and ask them to make a selection of the best Grasses for the purpose. And if it is possible for Grass to grow at all, he will in the course of time have a good turf. This is the plan I have tried, and I am satisfied with it.—E. H.

3572.—**Jasmines not Flowering.**—Perhaps the cutting back has been at fault. Lay in some of the best young wood at nearly full length and you will obtain flowers.

Uses of Lawn Mowings.—It is a waste of good Grass to make it directly into manure if there are any animals kept on the place; horses, cows, pigs, asses, and goats eat Grass cut with the machine readily.

Hollow Celery.—The early white Celery is apt to become hollow at this season, especially when sown early and checked in its growth.—E. H.

3570.—**Fir Trees for Screens.**—The common Spruce Fir will answer the purpose, and so will the common Yew and the American Arbor-vitæ, and the Cupressus Lawsoniana makes a quick-growing elegant hedge plant.

3577.—**Figs under Glass.**—Have the house 16 ft. wide. Grow the plants in large pots, and plunge the pots in a pit or border, lifting them annually, top-dressing frequently, and support with liquid manure when necessary. The Brown Turkey and White Marseilles are the best and surest bearers.

3574.—**Keeping Roots of Scarlet Runners.**—Dig up the roots and preserve them in dry sand. Examine them occasionally during winter, removing any dead or decaying matter. Plant again towards the end of April.—E. H.

3584.—**Scale on Peach Trees.**—Dissolve 6 oz. of Gishurst Compound in a gallon of soft water. Add one quart of Tobacco liquor and sufficient clay to make it as thick as paint. Apply it carefully with a soft brush when the leaves are down.—E. H.

3582.—**Sea-sand for Plants.**—I use sea-sand for all purposes, and with the best results. For years I have used it for bulbs of all sorts. I first wash it in plenty of fresh water, and then dry it for use.—G. R. BARRETT.

—— The salt in sea-sand is of no use to the plant which is being struck in it; the sand acts as a mechanical agent in keeping open the soil; it is to facilitate the passage of water and the retention of air; any coarse, gritty material is of equal utility.

3533.—**Fungus in Vine Border.**—Take out the soil from your Vine border, and replace it with good coarse loam, with a fair proportion of coarse bones added. If the fungus is only on the top of the border a mixture of soot and salt diluted with water would destroy it, but I would advise you to engage the services of a practical man to perform the operation.—T. LOWE, *Penketh.*

3584.—**Scale on Peach Trees.**—Wash the trees infested with a solution of Gishurst Compound, about 8 oz., to the gallon, then mix up into a paint a small quantity of soot, soft soap, and clay, and paint the trees carefully over. I have found the above the best remedy to exterminate this pest.—THOS. LOWE, *Penketh.*

3579.—**Acorns for Picture Frames.**—1. Shellac put in a bottle, and methylated spirit just sufficient to reach the top of the shellac; shake and get it dissolved. 2, Judson's Brown Dye

—— "Nil Desperandum" should buy about ½ an oz. of shellac and put it into about a tablespoonful of methylated spirit of wine. Keep it in a well-corked bottle until dissolved. Then apply it in the same way as glue to stick the Acorns in the cups; but use a common brush, as a good one will be spoilt.

3578.—**Passion Flowers from Suckers.**—My Passion flowers were four or five suckers pulled up and stuck round the edge of a pot in the spring of 1879; the same autumn I turned the potful out into a bed made with walls of turf, and filled with drainage and rich soil, plenty of manure, prepared for a Maréchal Niel. This year they made nearly a dozen shoots from 6 ft. to 13 ft. long, and bloomed very fairly during the past summer.—PAT.

3553.—**Palm Losing its Leaves.**—I know of a Palm, which having lost its leaves, was restored by being shook out and re-potted in good soil with plenty of leaf-mould. It was kept in a dwelling-house. The re-potting and nursing were done by an inexperienced lady.—PAT.

Although the following questions are answered by the Editor, he will be obliged to any of our readers who may think well to answer them according to their experience.

3668.—**Plants for Boxes on Greenhouse Shelves.**—*H.N.*—Hyacinths, Tulips, Squills, Lily of the Valley, Anemones, and other bulbs would do well in boxes on greenhouse shelves. They must have good drainage and good sandy soil.

3669.—**Pear Trees Not Growing.**—A twelvemonth ago I planted some pyramid fruit trees, two of which (Pears) did not "break" in the spring, and have remained as if dead. On examining them now, however, prior to replacing them, I find the wood plump and quite green when the skin is raised with the nail; the branches also break green and fresh, even at the tips. Is it possible for trees to remain dormant so long? and is there any chance of their recovering next spring? or must I consider them dead?—MAS ELOH. [It is not unusual for transplanted trees to remain, as it were, dormant during the summer after they are moved, and to break into growth the following spring. We would leave them till spring and see the result.]

3670.—**Azaleas Losing their Leaves.**—I have some sweet-scented and other Azaleas which are losing their leaves. Should they do so? They have been out-of-doors during the summer months, and are now in a cool greenhouse.—META. [The Ghent or hardy Azaleas are deciduous, and lose their leaves at this season, but Indian or greenhouse Azaleas are evergreen.]

3671.—**Crassulas Bare at the Bottom.**—*F. M. S.*—Cut the plants down to within 4 in. or 5 in. of the soil and put in the young tops as cuttings, using sandy soil or the purpose.

3672.—**Euphorbia jacquiniæflora.**—*H. E.*—This plant wants a temperature of at least 60° at this time of the year to keep it in good health. If 10° higher can be given all the better, provided the plants are not kept too far away from the glass.

3673.—**Planting Forget-me-nots.**—Is is right to plant out Forget-me-nots and Pansies for spring blooming into the beds at once? They have been raised in a frame, and I thought of planting Crocus bulbs, &c., at the same time, so as to keep up a succession of bloom in the flower-beds near the house.—E. P. [Plant at once if the weather continues open.]

3674.—**Flowering Almond.**—*John Williams.*—The flowering Almond succeeds well in some of the forecourts near London. It resembles a Peach tree.

3675.—**Adiantum farleyense.**—I have one of these Ferns, which has flourished until lately, but the fronds have turned yellow. It is kept in a moderately heated greenhouse.—EINNA. [Probably the heat is not sufficient to keep it growing through the winter. Keep the soil moist, and put the plant into the warmest end of the house. Do not wet the foliage. A moist heat is necessary for the well-being of this plant. It will no doubt throw up new fronds in spring.]

3676.—**Spent Hops in the Garden.**—Are spent Hops of any use as a top-dressing for Raspberries, Rhubarb, and Black Currants?—J. H. L. [They would serve as a mulch in dry weather, but their manurial properties are very small.]

3677.—**Cordon Peach Trees.**—*Rev. R. M.*—You would certainly succeed better with cordon Peach trees planted out in an orchard house than with trees in pots, provided the roots can be got at for pruning when needed.

3678.—**Wintering Tuberous-rooted Begonias.**—*M. C.*—Keep them in a greenhouse temperature, and gradually put them to rest by keeping the soil drier. Store them in a shelf or turn the bulbs out of the pots, and put them in a box of Cocoa-nut fibre.

3679.—**Arum Lilies.**—*M. C.*—At this time of the year these require a temperature of 40° to 50°, keeping them well supplied with water. If in small pots, liquid manure will be beneficial to them. When they have done flowering in spring re-pot them or plant them out-of-doors in rich soil, and lift them and pot them in September. Any good soil will do for them, but turfy loam and rotten manure or leaf-mould make the best compost.

3680.—**Heat for Conservatory.**—What degree of heat should a conservatory be kept at containing Azaleas, Geraniums, Camellias?—M. L. [40° at night. During cold weather a few degrees lower will not hurt, and during very mild weather a few degrees higher may be allowed. By day 45° to 50° will be plenty high enough.]

3681.—**Wintering Coleuses.**—*S. H. L.*—If you have not a warm greenhouse you will do little good with Coleuses. Your best plan would be to throw them away and get a few young plants in spring.

3682.—**Tropæolum Leaves Turning Yellow.**—*E. T.*—They generally do when winter approaches. Your flower is of the Lobbianum section.

3683.—**Pigeon Manure for Plants.**—*Wordsley.*—This is quite equal to fowls' manure. It is very strong, and should be used with care.

3684.—**Begonia Leaves and Pelargonium Blooms Falling.**—*F. J. L.*—We might tell the reason of this if we knew under what circumstances the plants are being grown.

3685.—**Heat for Hyacinths.**—*H. C.*—Hyacinths which have been potted and covered up in a frame for six weeks should be ready for placing in heat. Examine them, and if the pots are full of roots, place them in a temperature of 50° or 60° if convenient. If you can plunge the pots in a gentle bottom-heat, so much the better. Keep them slightly shaded from the light for a few days, and afterwards give them all the light and sun possible. It is not imperative that they should be very close to the glass if they are in a light situation.

3686.—**Removing Leaves from Christmas Roses.**—*F. L. L.*—Dead or decaying leaves may be removed, but it is not wise to cut off those which are green and healthy.

3687.—**Achimenes for Window Culture.**—*A. A., Stafford.*—Having shaken the bulbs out of the soil and put them into a pot of sand, you may keep them on a warm (but not hot) shelf till spring, when you may pot them in good soil, and place them in the window of a warm room. Do not water till you have potted them and they show signs of growth.

3688.—**Washing the Leaves of Geraniums.**—*A. A., Stafford.*—You are quite right in removing the dust from the leaves of your window plants, but you must be careful not to deluge the roots with water at this time of the year. A damp sponge is all that is needed.

3689.—**Chrysanthemums with Different Coloured Flowers.**—*P. H. S.*—It is not unusual for the Chrysanthemum to bear differently coloured flowers on the same plant.

3690.—**Mushroom Growing.**—I have a Mushroom house with all the appliances of hot water and shelves, but the results are not satisfactory. I have been now two winters without anything like a crop. I am told that the failure arises from the want of a shed to dry the horse droppings, and that this kind of manure only is of any use in Mushroom growing, and that the droppings from cows are useless. Is this so?—INDOCTUS. [Cow manure alone is useless for Mushrooms; horse manure only can be depended upon. The long straw should be shaken out of it, and it should be placed under cover and be frequently turned to let the rank steam out of it. Mix a few barrow-loads of good garden soil with it, and make the beds 12 in. or 18 in. thick. It must be well trodden or beaten down, and when the temperature of the beds is found to be on the decline spawn at once, and cover with a little sifted soil.]

3691.—**Planting Figs for Covering House.**—*J. E. T.*—Plant now or in spring. Virginian Creepers may also be planted now or in spring. We do not know what Flax you mean.

3692.—**Pear Tree for Front of House.**—What kind of Pear tree would be best to plant against a wall of house with a south-west aspect to cover a large space?—PAT. [Marie Louise.]

3693.—**Bulbs Out-of-doors.**—I wish to plant out-of-doors Hyacinths and Polyanthus Narcissus, purchased for pot culture, but fear they are too tender. How can I plant and protect them so as to be safe from frost? Will they flower freely outside?—VIX. [They will be all right if you protect the blossoms by means of canvas, or some similar material.]

3694.—**Covering Bare Walls.**—Having an ugly wall 8 ft. high which I want to cover, would you advise my making a box to place at the top, planting it with variegated Periwinkle to hang down?—G. EUSTACE. [We should rather advise making a good border at the foot of the wall, and planting in it quick-growing Ivy.]

3695.—**Washing Fruit Walls.**—When walls are washed with a mixture of Portland cement, grey lime, and copperas, ought the fruit trees to be untied? and will the mixture hurt them or may they with safety be washed over?—ELEANOR. [The trees must not be washed with such a mixture as you mention.]

3696.—**Strawberries for Forcing.**—*H. C.*—Put them in cold frames at once if you can do so.

3697.—**Loam.**—*Novice.*—The top spit of a pasture laid by and rotted is the soil known as loam. Clayey loam well when pulverised by the weather is well suited for plants if plenty of sand be added to it, and its heaviness is counteracted by a mixture of light leaf-mould or peat. Bog soil is of no use for pot plants; it goes sour.

3698.—**Camellia Buds Falling off.**—*J. H.*—See article in last issue of GARDENING.

Red Musk.—*R. J. Thompson.*—Mimulus cardinalis.

Books.—*Constant Subscriber.*—1 and 2, "Hobday's Cottage Gardening," price 1s. 9d., post free from our office; 4 and 5 we cannot answer.

Names of Plants.—*F. M. S.*—Hedychium Gardnerianum. It is not hardy, but may be planted out during summer.——*Saxon.*—1, Selaginella formosa; 2, S. denticulata; 3, Pteris serrulata.——*Moss Side.*—Selaginella denticulata. If the air of the room is very dry, you must keep the plant under a bell-glass.——*J. B.*—Kniphofia Uvaria.——*Mrs. R. P.*—Tradescantia discolor.——*R. A G.*—Asplenium Fabianum, Tradescantia zebrina, Platyloma falcata, Curculigo recurvata.——*M. R.*—Nerine crispa.——*M. J. M. B.*—Lycium barbarum.——*J. Stark.*—Begonia Weltoniensis. It is tuberous rooted and dies down in winter.——*A. B., Esher.*—3, Marie Louise d'Uccle; 4, Buerré Bosc; 5, Marie Louise; 6, Beurré Capiaumont; 8, Marie Louise d'Uccle.——*Dalton.*—1, not known; send when ripe; 2, Emile D'Heyst; 3, Althorpe Crassane.——*Leeds Subscriber.*—1, Pilea muscosa; 2, Cineraria; 11, Trachelium cœruleum; 13, Gasteria (species); 14, Phyllocactus (species). All the Begonias are varieties of B. Rex, except No. 8, which is B. argyrospila.——*Joseph Eustace.*—Cox's Orange Pippin, probably. We cannot be certain when only one specimen is sent.——*H. Mason.*—The Apples were crushed to pieces.

QUERIES.

To Querists.—*All questions are inserted or answered in these columns free of charge, provided the following rules are observed: 1.—Write clearly and concisely on one side of the paper only. 2.—Use a separate sheet of paper for each query. 3.—Give full name and address, with any nom de plume or initials you may wish used in the paper. Questions only of interest to the persons asking them should be accompanied with a post card or stamped addressed envelope for reply.*

3699.—**Material for Rockwork.**—I am about building a small house for the growth of exotic Ferns, and wish to form an artificial rockwork in which to plant them out instead of growing them in pots. Could any one inform me if there is any composition better adapted for the formation of the rockery than Portland cement, the colour of which I do not like? I have seen rockeries constructed with a material which had a very natural appearance and was of a nice brown tint, altogether far superior to Portland yet seeming to be cement of some kind. I want something more durable than cork?—R. W. J.

3700.—**Cost of a Greenhouse.**—In GARDENING for June 21, 1879, there are directions how to build a small greenhouse. Can any one give me an idea of the cost?—WORDSLEY.

3701.—**Creepers in Chalky Soil.**—What are the best Creepers for front of red-brick house with E.N.E. aspect? Soil chalky.—G. T. P.

3702.—**Hydrangeas in Pots.**—At a flower show held about two months ago I saw some pretty exhibits of Hydrangeas in small flower-pots. I should be very glad of some information how to grow them in this way. Perhaps some of your correspondents would kindly enlighten me.—TREMADOC.

3703.—**Slugs and Snails.**—My garden is terribly infested with slugs, which I have tried in vain to exterminate. I have just heard that a weak solution of corrosive sublimate in water is a thorough cure, used by means of a watering-can. Has any one tried this? and if so, in what proportion should the sublimate be used, so as not to injure the plants?—W. S. S.

3704.—**Clubbing in Cabbages.**—Will "W. S." (see GARDENING, October 16) be so good as to say what quantity of redlead he puts to his mixture? Say for a barrowful of loam and manure.—J. F.

3705.—**Building a Forcing Pit.**—Will some reader of GARDENING kindly give me practical instructions how to build and heat a forcing pit? I require a place to protect Geraniums, &c., through the winter, to force Celery, Cauliflowers, &c., and strike cuttings in spring, and to grow Cucumbers or Melons in summer. My garden wall (of stone) is 4 ft. high, and from there to the path in the middle of the garden is 6 ft. I would like to make the pit 18 ft. long, but do not know how to proceed. I, of course, want a maximum of utility at a minimum of cost. Will some reader kindly give me advice?—TREMADOC.

3706.—**Soil for Plants.**—Will some one kindly tell me when I should re-pot or basket a Stanhopea insignis? and what soil, &c., suits it best? It seems perfectly matted in roots and leaf-bulbs, the latter growing outside the basket. Also, what compost suits the Sanchezia nobilis best? I have a Pancratium fragrans in bloom now; when must I divide the bulbs? and what is the best soil for it?—C. B. Z.

3707.—**Chrysanthemum Bearing Differently-coloured Flowers.**—I have a Chrysanthemum which I have grown for some years. I have several of the same sort blooming this year; one is producing on one branch yellow flowers, another branch producing white flowers, another branch produces yellow and white flowers, one flower half white, the other half yellow. I may state that till this year all the flowers have been yellow. Can any one give an explanation?—G. P.

3708.—**Wintering Beetroots.**—One way recommended by "W. W." (GARDENING, Oct. 16) to winter Beetroots is to take them up and clamp them like Potatoes. I have succeeded in keeping Potatoes in first-rate condition through hard winters by taking up every alternate row for use and earthing up the other rows. Would a similar treatment not do to preserve Beetroots? Of course this season is now passing away, but a hint on the subject might be of service in future.—J. D.

3709.—**Plants in Glass Porch.**—I have a porch 6 ft. by 6 ft. attached to my house facing west, the entrance to which porch is north. The lower portion is of

wood to about 3½ ft. in height, with 6 ft. of glass to roof, which is also covered with the same material. I have one ventilator over door 2 ft. long by 1 ft. in depth; three shelves, one level with the top of woodwork, another 3 ft. above, and the other under roof. I cannot, however, make plants flower. They partly open, and then dry or wither off, and other plants grow scraggy and never flower. The glass on south side of porch is opaque, and the other sides (west and north) coloured and posted, the only transparent glass being that on the roof. What effect would this description of glass have on the flowers and plants, or is their failure attributable to improper ventilation? I am inclined to think both are to blame, but shall be glad to receive the advice of more experienced hands.—CORNUBIA.

3710.—**Diseased Pansies.**—Will any reader kindly inform me how I am to save Pansies from a kind of decay at the roots, caused, I believe, by some small grub or worm? The finer sorts only are attacked.—J. PRATT, *Durras*.

3711.—**Moving Large Apple Trees.**—Can large-sized standard Apple trees be removed without danger? and what is the best time and manner of doing so? I have some which were planted in a kitchen garden near to walls some eight or ten years since, and they begin to shade the walls and injure other fruit trees.—H. S.

3712.—**Fountain for a Fernery.**—I have a small greenhouse, which I purpose using as a Fernery; in the centre of my rockery I wish to have a small fountain; will some reader kindly inform me how it should be constructed? I wish it to throw the water about 3 ft. or 4 ft. from the jet; what kind of jet will be best? What size piping, and how high above the jet should the tank be fixed to get the necessary force of water? Any information will greatly oblige.—T. F. W.

3713.—**Tuberoses.**—I wish to grow a few Tuberoses. I have got four dozen from Holland. They have had their tops cut off about 2 in. above the bulb, and have no fibrous root. Will some good grower advise me as to their treatment, *i.e.*, size of pots, soil, where to keep them in winter after potting, and the best summer treatment, and what season of the year I can get the best flowers? I am not particular about having them early; next July or August will do.—TAFFY.

POULTRY.

Poultry Houses and Manure.—Allow me to offer a few remarks as well as to correct some statements made in GARDENING on this subject treated under the head of "On fowl keeping in small spaces." First, then let me assure the writer I most widely differ from his views as to the capacity for housing a small number of birds. I base my knowledge on experience, not mere theory. In speaking of this subject, he says (in allusion to Mr. Wright), "I should prefer a house at least twice that size for myself, *i.e.*, 10 ft. to 12 ft. square for accommodating five hens and one cock." Now, as we know that the primary cause of prolific egg production is warm housing, and as the heat derived from the bodies of the birds (generated within them, and supplied to the atmosphere around them) goes to produce such warmth, it very naturally follows that a greater supply of heat can be obtained in a small house, and consequently six birds housed in a space 5 ft. or 6 ft. square would be more profitable than if housed in double that space, because the heat generated would be greater, and if the sanitary precautions be fully and properly carried out this will prove the most profitable as well as economical means of housing. One word as to the manure. The writer in a recent number of GARDENING is of opinion that fowls' manure, unless exposed to the air for months and afterwards diluted, will kill whatever is treated with it. Now the utter fallacy of this to my idea is most obvious. Fowl manure is rich in fertilising salts, and consequently most valuable to enrich the soil. Submit such manure to the absorbent action of the atmosphere for a length of time, and you destroy that property which you should endeavour to protect (the fertilising salts); dilute it as soon as possible after obtaining it from your fowl houses, and you have a rich, safe, and valuable manure of incalculable value and service to the ground.—GEORGE R. BROWNE.

Poultry in Confined Spaces.—I have seen much written about poultry in confined spaces, but have never yet seen advice given as to the number of fowls that may be kept in certain sized plots of ground. I have a corrugated iron hen house made in the best manner, 10 ft. by 6 ft. by 7 ft. 6 in. high, with a run fenced in of 288 square ft., well protected from north and east, at the bottom of my garden, which is 150 ft. run. I keep a few good Silver Spangle Hamburghs, also a few good Minorcas, but should like to know about what number I could keep in above space not to be overcrowded. I believe many would be as pleased as myself to know how many fowls to keep in small spaces. Of course there are many who keep poultry in a much smaller space than mine and more closely confined with surrounding buildings, yet I have seen some very good fowls kept, and some the reverse.—E. W. H. H.

Can Fowls be Made to Pay?—A year ago we commenced poultry keeping with five pullets (Black Hamburghs) and a cock. They began to lay on October 19, and have continued to lay uninterruptedly till the end of September, after they had begun to moult, never having shown any disposition to sit. They have laid during the year 917 eggs. During the summer we added at different times to our stock two hens and a brood of chickens. Our poultry altogether have cost us for food during the year £2 9s., and we have sold or used 960 eggs. The value of these at a penny each (which is below the market price during a great part of the year) is £4, leaving a profit of £1 11s. Besides this we estimate our stock to be now worth at least 11s. more than they cost us, making a total profit on eggs and stock of £2 2s. Our fowls are exclusively confined to a grass run of 16 yards square. They have two meals a day—warm, soft food in the morning, and corn (often varied in kind) in the afternoon. They have in addition a few scraps from the kitchen, and occasionally refuse from the kitchen garden and mowings from the lawn. We think we have satisfactorily answered the question whether fowls can be made to pay even in a somewhat confined space.—ALPHA.

Cochin Fowls.—I have two Cochin cocks, one six months and the other four month old, and six hens. Are the cocks old enough to be of any use for breeding purposes?—META.

Black Hamburgh Fowls.—Will "T. F." tell us where we can obtain some of his wonderful Hamburgh fowls?—G. H. G. M. and BONUS.

Vermin in Fowls' House.—I beg to state my experience in ridding fowls' houses of vermin. I first washed the houses with a solution of Calvert's carbolic acid (1 oz. of acid to every two quarts of water), taking the houses to pieces as much as possible. As I found that the insects, which were chiefly of a red colour, mostly congregated in the cracks and crevices, I next limewashed the house, using the wash hot, and since then I have not seen or heard of any insects in the houses.—W. KIDDLE.

Preserving Eggs.—I have a great many eggs during the summer, but fail to get many during winter. I shall be glad if any reader will kindly tell me how to preserve eggs laid in summer so that they will be good for use during winter.—D. H.

Eggs for Setting and Perches for Fowls.—What length of time will eggs keep for setting? and what is the best way of keeping them? and what is the proper shape of perch for fowls to roost on, round or square? also what thickness if round and what size if square?—J. D.

Roup in Poultry.—I shall be obliged to any reader who will tell me what to do with my fowls. They commence as if they had got the roup, and continue that way for two or three weeks, and then swell about the throat and tongue and die. I have given them all kinds of pills, but they do no good. I give them fine sharps in the morning and Wheat and Barley mixed at noon and night, and they have a clean dry place to roost in.—LEARNER.

AQUARIA.

Fish Dying in Aquariums.—I have an aquarium which I purchased about six months ago containing one small gold, two very small, four larger fish, and several snails; since then it has stood in my shop (a chemist) about 7 ft. from the door. It has been supplied daily with fresh water brought from a leaden cistern by means of a leaden pipe, and from a little jet in the centre. When it came there was a greenish concretion nearly all over the inside of the glass which I had some difficulty in removing. I thoroughly cleaned the rockwork and the sand, and when the glass has become furred with a deposit from the water, I have sponged it off; have also drawn off the deposit from the bottom with an india-rubber pipe. I have since added three larger fish, taken from a pond, and two small gold fish recently brought from London. All the fish seemed well and lively, until one of the new gold fish began to show sign of a fungus growing over it. I removed it from the aquarium, painted it with a solution of bichloride of mercury, which removed all the fungus. The fish remained in a dormant state nearly a fortnight in a vessel by itself. I then put it back with the other fish; it seemed to recover rapidly, and was as lively as the others for nearly a fortnight. It has again gone wrong; so have several of the larger ones. I have taken out two dead, and have doubts about the others. I have fed them irregularly with a little biscuit, vermicelli, bread crumbs, and latterly with a few bits of raw meat cut small. At first I threw in a handful of Canadian weed, which gradually perished; recently a little Duckweed, and now a little Watercress. Can any reader kindly advise me how to preserve the fish I have left?—A NEW READER.

BEES.

Keeping Bees through the Winter.—"A Berkshire Bee-keeper" (see page 410) has in the main given very good advice, but if he is an old hand at the trade he will be thankful for a little friendly criticism. He recommends "A Weaver" to feed in October, which in the present case is wrong, as also agrees "One Taught by Experience." He also recommends a hole to be made with a gimlet in the top of the hive, but the gimlet would be much more likely to find its way into the combs than between them; a hole from 2 in. to 3 in. wide should be cut in the top of the hive, a piece of perforated zinc fastened to a hollow piece of wood sufficiently large for a pickle bottle to be inserted in it mouth downward, filled with syrup, and a piece of muslin tied over the top; the piece of zinc is very needful in many ways, which all who feed bees will prove. "One Taught by Experience" also errs in giving 1 pint of water to 1 lb. of sugar, as proper to feed them with. I need not tell old bee-keepers that such syrup would greatly injure, if not destroy, any hive of bees. A little salt should also be added to all feeding mixtures, a teaspoonful to about 4 lb. of sugar. In conclusion, I ask your correspondents to take my criticisms kindly, for I feel sure that they, equally with myself, are desirous of giving to our young bee-keeping friends sound and good advice.—APIARY.

Commencing Bee-keeping.—I should advise "Kensington" to commence bee-keeping at the beginning of next March in preference to buying a hive at the present time, for he will not then run the risk of losing them in the winter, and he must see that he procures one with a young queen. The price of a good 18-in. Pettigrew Straw Hive and bees in March is £2.

HOME PETS.

Birds for Outdoor Aviary.—I intend building an outdoor aviary for British birds, and shall be obliged to learn which, if any, should be excluded from the aviary. For instance, will blackbirds agree with linnets or wagtails?—H. A. M.

Goldfinches in Aviaries.—Having kept goldfinches for some years past, and all my pets having attained a green old age, I am in a position to inform "W. H. B." that his feeding is in fault. Hemp should be withheld except during moulting, and then it should be sparingly given. Linseed should form the staple food, with Maw seed for a change, or as a means of teaching the birds. The intelligence of the goldfinch is beyond that of almost any cage bird.—V. C.

—— I have had a goldfinch for many years subject to no ailments. The food given is canary and flax seeds, sometimes a small portion of Hemp seed, but the latter, although the birds are very fond of it, is by no means good for them used too freely, and may, in all probability, be the primary cause of premature death.—M. L. V.

Siskin.—*E. P.*—This is a name given to the Aberdevine, a bird closely allied to the goldfinch.

THE HOUSEHOLD.

Devonshire Clotted Cream.—The milk of cows milked either morning or afternoon is first strained and then put into pans to cool, and left for the head or cream to rise till next morning. The pans are then put on to a clear fire, or, better still, a hot plate on a close range, and there kept until sufficiently heated, which may be known if the cream is carefully pushed aside from time to time to see when the small air bubbles begin to rise. Directly bubbles are seen to be rising the pan must be at once removed and put aside to cool. Next morning, not before, it may be skimmed, and then the result will be clotted cream.—G. N. BARRETT, *Drakesleigh, Devon*.

Preserving Gourd.—Will any one kindly inform me the best way of preserving Gourds?—J. M.

Preserving Tomatoes Whole.—Let the Tomatoes become thoroughly matured, clean, and quite dry. Secure some wide-mouthed bottles, in which place the fruit whole, and fill up with best brown vinegar; when thus done, Tomatoes may be kept for any length of time. The small kinds look very pretty in the bottles done this way.—L. V., *Lewisham*.

—— Simply bottle and cover with cold vinegar; you may put what spice you please, or none; I prefer the simple vinegar.—C. J. PHILLIPS.

Pickling Tomatoes.—How are green Tomatoes pickled?—J. S.

GARDENING ILLUSTRATED.

VOL. II.—No. 90. *SATURDAY, NOVEMBER* 27, 1880. **PRICE ONE PENNY.** REGISTERED FOR TRANSMISSION ABROAD.

PALMS.

THE Palm family is one of the most important of cultivated plants. For room, conservatory, or stove decoration Palms are always valued, and some of the kinds will even succeed in the open air in warm southern countries. Latania borbonica, the subject of our illustration, is one of the most useful Palms, either in a large or small state. When planted in a tub or border of good soil this Palm attains large dimensions, and its fan-shaped fronds are both graceful and effective when associated with Tree Ferns and similar plants in large conservatories. If confined to a small pot it will thrive for several years without repotting, and when it gets too large a portion of its roots may be cut off without fear of serious injury to the plant. As regards general culture of Palms perhaps a few notes describing the way they are grown for market may be most useful. There is always a large demand for Palms in the market, and at all seasons of the year we find them liberally associated with flowering plants in the florists' shops. They are principally raised from imported seeds, sown in pots and pans, and placed in bottom-heat. When the young plants are up, they are pricked out in other pans or boxes, until they get again established, when they are potted off singly into 3-in. and 4-in. pots in good rich loam and peat. Plenty of heat and moisture are given them; as they progress, they are potted into 5-in. and 6-in. pots, and, before being sent to market, they are exposed to a cooler temperature, in order to harden them a little. Some are potted in large pots, but the pots generally used are 6-in. ones, and in these large and healthy plants are grown. Among the best and most appreciated market Palms is Latania borbonica, which is easily raised from seed, and grows rapidly, good saleable plants of it being obtained in three or four years from the time when the seeds are sown. Corypha australis is a common kind, also largely grown; it is hardy in character, and, being neat in appearance, is largely in demand for room decoration—a situation in which it lasts in a healthy state for a longer period than perhaps any other Palm. Latania altissima is likewise largely in demand, but as seeds of it cannot be obtained in very great quantities, it is seldom found in the market in large numbers. Another good Palm, equally difficult to procure, is Rhapis flabelliformis; it has a graceful habit, and when grown to a height of 2 ft. or 3 ft., is very handsome. Another excellent Palm is Cocos Weddelliana, a light and elegant kind which has not been very long in commerce, but seeds of it having been obtained in large quantities, it will, no doubt, be largely grown for market in years to come, as it appears to stand the rough usage to which such plants as are taken there are subjected, and also to thrive with proper attention for a long time in a sitting room. Areca crenata and A. Herbsti are both dwarf, compact growing Palms of great value for market purposes; their stems are furnished with sharp black spines, their stalks are of a reddish-bronze, and the under sides of the leaves are beautifully glaucous. Some of the Kentias (one of which we lately figured), too, are much thought of, but they are rather scarce.

THE AFRICAN FAN PALM (LATANIA BORBONICA).

Christmas Roses.—I have frequently wondered why these are not oftener made subjects of special culture in gardens than is the case considering their value as a winter flower and their easy management. I have a pretty extensive and well-selected stock of herbaceous plants, but amongst them nothing is thought more of than the Christmas Rose, which produces its pure white flowers in the depth of winter, and without forcing or attention. A good deal has been said about the white Abutilon Boule de Neige, as a handsome white flowering plant, but we have had both it and the Christmas Rose in flower at the same time, and we certainly give the preference to the latter. Though they resemble each other a good deal, the Abutilon is poor and frail compared with the Rose, the waxy and pure white flowers of which are far better adapted for decorative purposes than those of the Abutilon. Indeed, the flower-buds, just before they fully expand, are quite equal to those of the white Rose, as far as appearance goes, or a Camellia bud, and they are often used instead of them for button-holes, set up in a Fern frond or green leaf. I notice that they are extensively used for such purposes in towns about Christmas time; but the supply is by no means abundant seemingly. I would strongly recommend every possessor of a garden to plant Christmas Roses extensively, but they must be careful to get the pure white kind, for there are numbers of species and varieties. Helleborus niger is the best kind, and the Scotch variety of this, which is semi-double, is said to be much the finest; but I doubt if it surpasses the single one, which is so particularly attractive in the bud state. Helleborus atro-rubens, which has red flowers, is also described as a handsome kind, but I do not think it is worth growing; and the same applies to H. orientalis, which has flower of a dirty greenish hue, altogether inferior to those of the pure white kind. The latter is extremely hardy, and will grow in almost any soil and in any situation, but it deserves a good position in order to have it in flower early, for its blooming about Christmas depends a good deal upon the weather. In some winters, after a long continuance of soft, mild weather, the flowers are all up by the new year, but in some seasons they do not expand till the month of March. A good sunny position on a south border, however, hastens their progress; a handlight placed over each plant helps also to push them on, and at the same time keeps the flowers clean—an important matter, for they get so bespattered with mud when exposed to heavy showers as to be almost unfit for use, and attempting to clean them only makes matters worse. For this reason it is best to grow the plants in isolated patches, about 2 ft. across or less, for the sake of protecting them conveniently, and the lights or cloches should be put on them in November. The Christmas

Rose is propagated by means of seed and by division, but the latter plan is the best and most expeditious. Single crowns detached and planted in good soil will make large plants in a short time, It is an excellent plant for shrubberies, and should be planted freely in all warm and sheltered corners. In such situations it should be planted as extensively as Daffodils, Crocuses, Snowdrops, &c., which it just precedes in flowering, and, being an evergreen with handsome foliage, it is interesting at all seasons of the year. C.

HARDY FLOWERS FOR SMALL GARDENS.

Those who have a free, well-drained soil to deal with may include in their collection of hardy flowers a few of the many beautiful varieties of—

Clove Carnations and Border Picotees.—The most suitable soil for them is a sandy loam, which does not clog and get sour in the winter, but in which the plants do not easily suffer from drought in dry weather. Both Carnations and Picotees like to have the soil made firm about their roots, as in that case they do not suffer so much from alternations of temperature or excess of humidity, caused by heavy rains. I should caution your readers who may be inclined to attempt the culture of these much admired flowers that they must not expect to attain anything like satisfactory results with them unless their wants in the way of a proper rooting medium be attended to; but, providing that this is done, there is no reason why even the choice kinds should not thrive, even in gardens which are not so favourably circumstanced with respect to light and air as might be desired. It is a fact that some of our most successful growers of this fine family of hardy flowers have exceptional difficulties to contend with, being situated in the immediate neighbourhood of large towns and subjected to showers of blacks and even of metallic dust. It will thus be seen that no one who has sufficient space at command need shrink from undertaking the culture of the choice varieties of Carnation and Picotee, and it is to be noted that the greater the difficulties to be overcome the greater demand is there upon the skill, resources, and ingenuity of the grower, the effect of which is to sharpen his wits, and oftentimes give him a better insight into the details of culture and a more intimate acquaintance with the plant itself than would be the case where conditions of growth are naturally of a very favourable nature. There is also the legitimate pride arising from the knowledge that success has been achieved in the face of great natural obstacles, as well as the honour which must accrue to the successful Carnation grower to be taken into account, and I am sure that the small grower who may take this plant in hand, with a firm resolve to conquer the difficulties of culture, will find a rich reward in so doing, and will acknowledge that the result justifies time and labour expended. An impression exists that the Carnation is a tender subject, but the fact that some of the best growers reside in the north of England is a sufficient proof that there is no real foundation for this idea. The Carnation does not fear the cold when conditions generally are right, but it succumbs to extremes of wet and cold, alternate thawings and freezings when the roots are in sour or retentive soil, so sapping the vitality of the plants that they at the least fail to exhibit the luxuriance of growth indispensable to the production of good bloom, and oftentimes entirely disappear. Thus it will be seen that a good depth of free soil must be secured, and that where the natural staple is too retentive or tenacious, it must either be drained, or the beds must be thrown up somewhat above the ordinary level. Supposing that a collection of Carnations is desired, the proper way will be to throw up the soil into a rough ridge and let it remain thus until the beginning of March. Those purifying agents, frost and wind, will by that time have done good service, and will have sweetened every particle, and brought it into that free, friable, mellow state so indispensable to the continued welfare and activity of the slender, fibrous, hair-like roots of the Carnation and Picotee. The first step being well accomplished, the next will be to ensure porosity by adding some river sand, leaf-mould, road scrapings, or anything of a like nature in sufficient quantity to effect the desired end. This, of course, is only needful where the natural soil is clayey and retentive. Light, sandy, and alluvial soils are, on the contrary, benefited by the addition of a more holding and nourishing compost. The best time to plant is either early in October or in March; if planted anywhere during the last-named month, they will form fine specimens by the end of the summer. In the case of named kinds, the chances of success are increased by planting in a bed where each plant stands free from its neighbour, and where it is not liable to be crowded on by fast-growing subjects, such as is often the case when they are situated in a mixed border. There, too, every necessary and special attention can be given; and should a slight protection be deemed advisable it may be given, a few Hazel rods bent over, and a mat or two placed on them, being all that would be needful.

Violets.—These unassuming and fragrant flowers must be considered almost indispensable in every garden, and there are few places where a suitable situation could not be found for them. There are various ways of growing Violets, varying in their simplicity, for even where anything like high culture is attempted the cultural details are extremely easy to carry out. The easiest way is, of course, to well prepare a piece of soil in a sheltered and somewhat shady situation, and leave the plants to themselves for several years. In this manner and with just an occasional top-dressing of some light, free soil, a fair amount of flowers will be produced. If, however, high quality as well as abundance is desired, then an annual supply of young free plants with well developed and matured crowns must be provided. The young runner-like growths made early in the year must be taken off and dibbled into a free piece of soil in a shady situation. Keep them well watered until they have become furnished with roots, and then transplant them into a piece of soil which has been previously well worked and manured. Set them out in rows some 6 in. apart, keep them clean, water copiously in hot weather, and the result will be fine strong plants suitable for any purpose. This is the proper, and I might say the only, way to get good plants for pot culture, as plants taken up indiscriminately from a thick bed are seldom satisfactory. The Violet loves a certain amount of shade, and that protection which a stronger vegetation affords it when growing naturally, and consequently is found to thrive best in a garden where a cool and partially shaded situation can be accorded it. At the same time it will grow freely enough in the open where the soil is rich and deep, but should be kept well watered and sprinkled overhead at least twice a day in hot weather, in order to refresh and invigorate the foliage, and to keep at bay that destructive insect red spider, which is apt to infest the plants to an alarming extent where the atmospherical conditions are favourable to its increase.

Pyrethrums.—This is a family of hardy flowers the merits of which can scarcely be over-estimated. Thoroughly hardy, of free, quick growth, flourishing in almost any soil, but attaining a high degree of vigour in well-stirred ground, and bearing a large amount of fine showy flowers, embracing shades of carmine, red, white, and lilac in many varieties, of perfect form, charmingly quilled, and perfectly double, what more need I say to recommend this fine family of hardy perennials? Few hardy flowers can boast of such a combination of high qualities as the Pyrethrum, and I feel convinced that when better known it will take a foremost position in gardens generally. For cutting purposes the flowers are invaluable, as they last a long time in perfection, and wherever a few plants are grown there are sure to be at all times during the summer some good flowers to cut. The plant is so easy to grow that I need scarcely give any directions upon that point, but I may observe that deep culture, with plenty of manure and copious waterings in hot weather, is essential to the production of first-class blooms and continuous flowering.

Summer-flowering Chrysanthemums.—The uncertain nature of our climate, exposed as we are during the autumn months to storms and severe frosts, renders the culture of Chrysanthemums generally in the open air somewhat disappointing, for after all the care and labour which the grower may have expended upon his plants, he often experiences the mortification of having his best blooms cut off by frost, his hopes of a good display being thereby, of course, quite ruined. Where no glass accommodation exists for the protection of the plants when coming into bloom, my advice would be to rely upon the early flowering section for an autumn display, as by stopping once or twice during the early part of the summer, even the earliest flowering kinds may be thrown into bloom in early autumn at a time when the glory of tender plants is on the wane, but before the blooms are liable to be injured by frost. The culture is the same as that required for the autumn flowering varieties.

Byfleet. J. Cornhill.

Double Flowers.—Flowers, like almost everything else, are subject to fashion. To bring each and all to the highest degree of doubleness now seems to be the aim and desire of many. I know several gardens where in the beginning of the year, though there are many Snowdrops, they are all double, and instead of the gracefully hanging "drops of snow" there are these stiff, flat, spreading, green and white blooms. It cannot be said that they are ugly, for a really ugly flower is hard to imagine, but if the two could be compared side by side, I think the palm of beauty would at once be given to the single variety. This illustrates my meaning, and as it is not yet too late to plant Snowdrops, the single kinds deserve a trial by those who have not already done so. In Nature, very few wild flowers are found at all double. The simplicity, gracefulness, form, and naturalness seem entirely lost in many double flowers; they look so stiff and formal. Where is the grace in a double Violet? The Tulip, Wallflower, Anemone, and Fuchsia are instances; many others might be mentioned. It must be acknowledged that it is not the same in all cases, far be it from me to prefer a single to a double Rose; it is moderation that is wanted. Because some are better double is no reason why all should necessarily be so too; the happy medium, though perhaps hard to find, is always best. I can hardly expect everyone to entirely agree with me, but many, perhaps, have never thought about it one way or the other; to them I recommend single rather than double flowers. —Martagon.

Hyacinths in Beds or Borders.—These should now be planted. They do well in any light garden soil, but tufty loam, with a plentiful admixture of sand and well decayed manure, is perhaps the best of soils for them; and if the natural soil be so stiff and adhesive as to require modifying, these are the materials that should be used. The bulbs should be planted with their crowns 4 in. below the surface, covering the ground after planting with 2 in. of loose pulverised manure as a protection against frost. Hyacinths planted out-of-doors seldom require any water; and if the soil or situation be at all damp, they will do better if the soils in the beds or borders be raised 1 in. or 2 in. above the surrounding level.—W. P.

Dividing Primroses.—Choice kinds, both double and single, should now be lifted, or if in pots they should be shaken out, the crowns divided and repotted in small pots. These should then be placed either in a cool house or in a frame for the winter. Weak crowns may remain in these pots all through the ensuing summer, but larger ones will doubtless bear division again in the spring after they have done blooming. Frequent propagation is beneficial, as by that means the bane of Primroses, a long woody base at the root, is not allowed to develop. The more roots issuing from the immediate base of the foliage the better.—D.

The Polyanthus.—There is no hardy garden plant to which the amateur can more pleasantly devote his spare hours than the Polyanthus. The culture is simple and inexpensive, the plant hardy, and easily raised from seed. It is only when it is desired to purchase plants of the comparatively rare florists' kinds that cost enters largely into the matter. I would not advise any one to embark in the growth of these choice kinds unless some experience has been previously obtained. As a rule the plants propagate slowly and are of a somewhat miffy

habit, are subject to the attacks of green fly, root rot, thrip, and other evils, and will sometimes, even when looking quite healthy, suddenly collapse. The most satisfactory kinds are those known as Fancies, or perhaps better classed as border varieties. These are all robust, give an infinite variety of colours and markings in the flowers, and are most easily raised from seed. A large batch of plants raised from seed sown as soon as ripe in 1879 were kept in a frame through the winter, and now some of them are in bloom. If the season be mild and open many will carry flowers up to Christmas. This autumn bloom is the product of strong, early-matured crowns, and come from good, free culture, and a free-growing season. We find if seed be sown every year, saved from the best flowers, that the average quality of the strain is greatly improved. If seed be sown in the spring, the majority of the plants raised will of course bloom the next year; but if sown as soon as ripe, and the plants kept under glass through the winter, many will bloom the first year, and in the second make fine plants. The best of these selected may be potted up in the autumn to make very good show plants in the spring, or if not wanted for that purpose will be very effective either in the greenhouse or in the sitting-room window. —A. D.

Anemones in Succession.—Among the most useful plants for spring flower gardening are the double scarlet Anemones, and it is a colour difficult to obtain. To have a good show of these, it is recommended to plant half the tubers in October and half in December, the later ones being planted between the early ones; this gives a long succession of bloom.—M.

VEGETABLES.

Forcing Seakale.—Many who could not obtain much stable manure have been in the habit of waiting till Seakale came in naturally, deterred by the great expense incurred by their wealthier neighbours for scores of Seakale pots and heaps of manure. But these are all unnecessary. The true way is to carefully take up well-grown roots, bring them indoors, and force them or make some little arrangement near the frames or manure heaps for that purpose. A trench in a Mushroom house will do admirably for forcing Seakale; so will a box made over a hot-water pipe; so will a pit or dark nook under the bench of a warm house, or, in fact, any place in which a little warmth occurs. For instance, nothing is more common than to find a flue or hot-water apparatus heating some surface other than the interior of the house, and by placing the Seakale in a wooden box against this it may be forced most easily. There can be no difficulty in providing a suitable place for it if there are houses, or frames, or pits in the place. In places where there are no hothouses, the best way is to devote a box or little pit in some shed, cellar, or outhouse to Seakale forcing, and in it to place 6 in. or 8 in. of horse droppings, which would start the Seakale into growth. Wherever there is a proper Mushroom house, one of the shelves may be advantageously devoted to the forcing of Rhubarb, Seakale, Chicory, &c. This is a most convenient way, all that is necessary, in addition to packing the roots on the shelf, being to hang a piece of canvas or a mat before the bench to exclude the light. These remarks will suffice to point out how the forcing of Seakale may be most conveniently done. Any place affording a genial heat, and either dark or light will do. Dig up the roots when forcing is about to commence, and put a portion in heat, following at intervals and in such quantities as circumstances may direct. Injure the roots as little as possible in taking up, and put by the long thong-like points in a bit of soil in a shed somewhere to be put in as cuttings, or rather as plants, to succeed those taken up for forcing. Of course, to be blanched the plants must be in the dark. Market gardeners dig out a trench in the open air 3 ft. deep, and fill it with manure, with a few inches of soil on the top, and then plant the Seakale roots close together. The soil thrown out of the trench makes a wall all round on which can be laid thin boards to be covered with long manure, or mats, or common dry Fern, as the case may be. —T. W. C.

Garden Turnips.—Among these, Cattell's Silver Ball is a handsome variety and good in quality; Early White Stone is soon fit for use, but it also soon runs to seed; the American Red Stone is a useful hardy sort; Chirk Castle, a black-skinned kind, is very hardy, and keeps firm and good for a long time; but Veitch's Red Globe has proved the best of all I have tried. These were all sown the second week in April on a south border, and were well supplied, when necessary, with water. They grew well, but later in the season the white kinds rotted very much, while the red ones kept sound. Afterwards, the white kinds were sown on a north border with the same result, nearly the whole of the crop rotting away. I have now another crop, consisting of red ones in use, which are all that in any way could be desired. —W. D.

Late Scarlet Runners and French Beans.—I only sow one crop of these, and that about the first week in May. The plants from this sowing are well supplied with water, and the Beans are gathered as they are wanted; but I make a point of clearing off all Beans at least once a week, and if any of them are too old for use, they are discarded, as, if only a few pods are left to grow on the plant for seed, they very much shorten the season of gathering—a circumstance too often overlooked in many gardens, and hence the cause of their being so soon over. I wholly attribute my success, as to later gatherings, to the regular clearings which I make. When there are signs of frost, I cover both Peas and Beans in bearing with hexagon netting, a most useful material for such purposes.—W. D., *Maidstone*.

Potatoes.—GARDENING ILLUSTRATED has supplied us lately with many interesting articles on Potato culture for home use, exhibition, and for market. Allow me to suggest still another method, which has been tried with great success by Mr. Harwood in his nursery, within four miles of Torquay, and this on rather a stiff, retentive soil. In August the haulm, then quite green, is pulled not quite out of the ground, just sufficiently to break the roots. This is found to hasten the ripening process, check disease, and last, but not least, prevent the second growth. By this method Mr. Harwood assures me that his crops of Potatoes are superior and sound.—T. FRIPP.

Autumn Planted Potatoes.—I quite concur with the remarks of Mr. Thomas Cowburn as to the waste of space in planting, as named by "Gardener," and again I fail to see that any possible advantage is gained in autumn planting so far as Potatoes are concerned. Unless the soil is very light and dry, and also well drained, it is sure to become consolidated, and in many cases wet and cold during winter, and as both theory and practice teaches that this is bad for the Potato, there is no gain in this respect. Again, weeds find soil which is not disturbed well suited to their growth, and they start before the Potatoes. My idea of land for Potatoes is that which has been ridged for the winter, and which has been forked over in spring, and made as dry as possible, and if a light dressing of dissolved bones is applied to the ground after planting, so as to be drawn up to the roots at the first hilling, so much the better. This year I had 17 bushels of Magnum Bonum Potatoes from half a bushel of seed planted. Perhaps those advocates of autumn planting who have such great successes would kindly say what their soil is like, what after treatment is given, and also state what failures they have. This past season having been such a good one for Potatoes, it is hardly fair to take it as a criterion of any system.—W. J. MAY, *Walton-on-Thames*.

My Experience of Potatoes in the South.—"Burns," in GARDENING, Nov. 6, page 430, gives his experience of Potato growing this year in the North. I will give my experience as an amateur in the South, viz., Brighton. On March 28 I planted 1 peck (14 lb.) of American Rose, of the same strain of seed I had used the past four years. The peck gave me 5½ bushels of magnificent tubers, some weighing 16 oz. and over, and in boiling, instead of being waxy, they were like balls of flour. This I can only account for through the comparative dry season. Such a crop as this, and not one diseased, is of rare occurrence, I think. The first week in May I planted 4 gallons (28 lb.) of Magnum Bonum, purchased of a local seedsman. The haulm grew nearly 6 ft. high, and was green when I lifted the Potatoes in the middle of October. The 28 lb. gave me 15½ bushels of fine tubers; three of one root turned the scale at 3¼ lb. I never dug such an even, clean crop; but they are not, as advertised, "Disease resisting;" many of mine have gone bad since being up, although well dried before storing. Snowflake has also turned out wonderfully well. I may say that my garden has had but little manure since 1877, as we have expected the builders across it since that time, and have kept expenses down, but in 1878 I gave it a good coating of lime, and to this I owe, I believe, my good crop, and the ground now is what I may call in "good heart."—W. B.

CARNIVOROUS INSECTS ON PLANTS.

IN GARDENING, September 25, you were kind enough to insert a communication of mine, under the initials "H. H.," referring to the above. On October 9, a correspondent, "V.," was good enough to throw some further light on the matter. Since then Mr. Butler, of the Zoological Department, British Museum, has favoured me with some correspondence on the matter, and as it is kindly coupled with a permit to make what use I please of it, I place it at your disposal, feeling sure that it will not only prove interesting to "V.," but to other of your readers. Mr. Butler says: "The fly which you forwarded to us is Cheilosia quadrata, one of the common sun-flies of our gardens. The larvæ of this and allied species are common upon aphis-infected flowers, and, being very voracious, are as useful in devouring aphides as are the larvæ of the common ladybird (Coccinella bipunctata). I have frequently reared both. It is my belief that the introduction of ladybirds into a greenhouse would be more advantageous thanthat of sun-flies, since the perfect insects are equally aphidiphagous with the larvæ, and would be more likely to breed in confinement than the flies. From what I have seen of the latter in a house, they appear to be contented to sit quietly all day upon the glass or to use their legs only until death terminates their imprisonment."

It has been shown by frequent experiments that almost all (if not all) caterpillars feeding upon the Gooseberry and Currant are so acrid, that neither birds nor lizards, frogs nor toads will eat them. Your correspondent "V." states that he gave such caterpillars to his ducks, and after the first trial they refused them; this is exactly in accordance with experiments which were made by Mr. Jenner Weir and myself some years since (our papers appeared in the Trans. Entom. Soc., London) with lizards, frogs, and spiders, and it will be useless for "V." to try to persuade a duck which has once tasted a nauseous caterpillar to touch it a second time, unless indeed its memory is shorter than that of the animals upon which we experimented. The term "noxious" is perhaps too strong a word to use; "unpalatable" would be more to the point. Wallace's natural selection will refer you to my paper on the rejection of certain larvæ and insects by lizards, frogs, and spiders. Mr. Butler's correspondence further bears out my proposition that wholesale syringing has its disadvantages. H. H.

American Cranberry.—We omitted to state in the article on this Cranberry (p. 414 of GARDENING) that plants of it can be obtained from Messrs. Dick Radclyffe & Co., seedsmen, 128, High Holborn, who are introducing it into England.

Worms in Pots.—A very good way to get rid of worms in pots is to put about ½ lb. of mustard in a large can of water, stir it well, and water the plants with the mixture; this will cause the worms to come to the surface, when you can easily pick them off. I have found this plan very successful with fruit trees in pots in the orchard house. It is practised in Mr. Rivers' nursery at Sawbridgeworth, where it is found very efficacious in all cases, but I can only speak from my own experience in the case of fruit trees.—GEORGE A. PASSINGHAM, *Milton, Cams.*

Destroying Wasps' Nests.—I saw in a late issue of GARDENING a paragraph recom-

mending a gunpowder squib for destroying wasps' nests. I have tried it and blasting fuse, but find nothing so effectual as the cyanide of potassium. Dissolve 2 oz. in a wine bottle of water; soak a soft rag with the liquid, and lay it at the hole where the wasps go into their nests, and every one that passes over it, either going in or coming out, dies. In this way I have destroyed 105 wasps' nests in my neighbourhood this summer, and I have never known it to fail. After the rag has been laid a short time it may be necessary to clear away the dead wasps and damp it a little more with the cyanide.—N.

House and Window Gardening.

Aralia Sieboldi.—This is one of the best window plants that can be grown. It is hardy in sheltered situations, but thrives best when placed in a window or greenhouse during the winter. It is easily propagated from sections of the stem or cuttings of young growths, and if planted in good soil it quickly grows into handsome plants. It requires plenty of water at the root, for if allowed to get dry it loses its leaves. Give all the air possible, and sponge the leaves once a week with clean water, so as to rid them of dust. Turfy loam and cow manure make the best compost for it, but it will grow in any ordinary garden mould. A little soot water given occasionally when the pot is full of roots will impart to the leaves a black and glossy appearance. There is a variegated variety of this plant, but by many it is not considered of so much importance as the green-leaved kind.

Aralia Sieboldi; one of the best of Window Plants for Winter.

Aspidistra lurida variegata.—If I were limited to the choice of one fine-leaved plant for room culture I should unhesitatingly choose the subject of the present note. I do not know of any one plant which will last so long in unimpaired beauty with a minimum of care as this. Give it a fair supply of moisture at the root, and a good washing of the foliage now and then, and it will remain in good condition for years. That which renders it of great and especial value to window gardeners is the fact of its throwing up its broad handsome leaves from a root stock, so that, unlike the Grevillea, Acacia, and many favourite fine foliaged plants, it does not ever much increase in height, and consequently does not get too big for the space. The type has green leaves, dark and glossy as the Ivy itself, and possesses the same valuable characteristics, but is, of course, by no means so attractive as the variegated variety, the lively variegation of which renders it at all times bright and attractive.—C.

The Fennel-leaved Fern (Asplenium fœniculaceum).—This is really one of the most elegant species of the genus Asplenium, and is worthy of a place in any collection of Ferns. The fronds are, as the specific name designates, finely divided, and are moreover of a lively and refreshing shade of green. It succeeds very well in a window in either a cool or warm apartment, for, like many species of this useful genus of the Fern family, it is of an accommodating nature, and will thrive in almost any situation, providing its needs, in the way of watering and cleansing the foliage, are attended to. Like all other members of the Fern tribe, it is impatient of stagnant moisture at the roots. Care must therefore be taken to give ample drainage, and not to over-pot. Ferns like plenty of moisture at the roots, but this cannot well be given until these latter touch the sides of the pot. Therefore do not shift until absolutely needful, and then place in the next sized pot.—J. C., *Byfleet.*

Asters as Vase Plants.—Four weeks since I pulled up a root of dwarf Asters bearing five or six blossoms and planted it in a vase of water. Some of the flowers are fresh now, although the foliage withered a week ago.

Improving Lawns.—The chief cause of the wearing out of the Grass on lawns is the continual removal of the produce from it by almost constant mowing and sweeping, and bringing nothing back to supply the waste. No crop could long stand the wear of this system without showing signs of deterioration and exhaustion. Of course, where the land has been well prepared and deepened before being laid down in Grass, the period of exhaustion will be longer in occurring, but come it none the less surely will, unless some assistance be given in the way of top-dressings. There are two principal modes of improving worn-out lawns—one, by taking up the turf, manuring and improving the soil underneath, and relaying it as soon as the work can be properly done; the other, by giving rich top-dressings. The former usually answers best, but much improvment may be effected by top-dressings in February over the surface of the Grass, to be followed by sowing a few fine Grass seeds, and about 2 lb. per acre of white Clover. If the Grass be not much worn, the Clover seeds alone will be sufficient. White Clover is an excellent plant for dry soils, as it roots deeper than most Grasses, and consequently maintains its colour and stands drought better, but it will not grow under trees. We are accustomed to look upon earth worms as a nuisance, but were it not for the annual top-dressing which they gratuitously bestow, the condition of many lawns would be worse than it is. The best way of improving lawns that are worn and weedy is take the turf up, improve the soil, and relay If new turf can be easily obtained free fr weeds, a preference should be given to it; if, in cutting up the old turf, it is cut very th most of the weeds, such as Plantains, Daisi &c., being strong rooted, will be cut throu and perish, as the main part of their roots w be left in the ground. When such work done before Christmas, the turf, even when c thin, has plenty of time to get well established fore drying weather sets in in summer. As the se son advances, and the Grass, from having be closely shorn, loses its first vigour, it is a go plan to remove the collecting-box from the mo ing machine, and allow the Grass to be distri buted over the surface for a few weeks. It astonishing how soon the cut Grass withers an disappears, and if continued for a month or s it forms such a mulch over the roots of th Grasses as effectually screens them from th blazing sun when drought sets in. There ar places in which this plan might be objectionable but the eyesore is really very little. If th Daisies be numerous, the scattering of the Gras mowings should be deferred till they have ex hausted their blooming capacity, or some of th flowers may produce ripe seeds, which will grow and still further increase their numbers. A sprinkling of soot and salt mixed with wood ashes will be beneficial as a top-dressin in February or March for all lawns on whic the Grass is weakly. Five or six cwt. of salt may be used to an acre with safety; the soot and ashes may be used liberally and will be most beneficial in strengthening and improving the colour of the Grass. Lawns that are kept in good order are seldom infested with Moss to an injurious extent. Of course, where Moss does become established, it ultimately masters the finer Grasses; but where the mowing machine and roller are regularly used, it seldom gets unsightly.—E. H.

Trenching for New Plantations.—Wherever planting operations are intended to be carried out, whether it be in orchard or shrubbery, it is important, if a profitable result is desired, that the ground should have been previously well prepared. Whatever is worth doing at all is worth doing well; and although trenching involves expense, still I am convinced such operations will, in the long run, pay. The most thriving plantations with which I am acquainted were trenched 20 in. deep, and the bottom of the trenches well broken up with the pick, the subsoil (poor sand) was brought up to the top, and the top spit placed in the bottom. It should always be borne in mind that in a plantation of young trees there is very little chance of improving the lower stratum of soil after they are once planted, but in the preparation of the ground, if the bottom spit is brought to the surface, the exposure to the air, together with the falling leaves and other decomposing vegetable matter, will materially improve it. I grant the young trees may not start so rapidly during the first year or two, in consequence of the best soil being placed at the bottom of the trench, but as soon as the roots begin to strike downwards, the effect of the deepening of the soil will soon be apparent, and in ten years it will be still more remarkable.—H. E.

Keeping Seeds.—To retain the vitality of seeds as long as possible, they must be preserved from the influences of heat and moisture. It is desirable that they should never be subjected to a higher or lower temperature than 40°, but it is absolutely essential that they should be kept dry. The moment a seed comes in contact with moisture it begins to grow if the temperature is high enough, and if not then placed in circumstances congenial to its development, as in the soil, it will of course perish. Without moisture in sufficient quantity to excite growth, however, seeds may be subjected to a much higher temperature than 40° without any immediate bad effects, though a high and dry temperature impairs their vitality; hence it is that seeds that have been kept for several years do not germinate so vigorously, though they are generally more fruitful. For this reason, old Melon seeds are preferred to new, as they do not run so much to vine; and when new seeds only of a variety are to be had, some gardeners carry them in their pocket, or keep them in a warm room for a while to effect the same end.

On the other hand, it is equally necessary to keep seeds dry under a low temperature—42° being the growing point, or lowest temperature at which seeds will germinate as a rule; exposure to damp below this figure promotes decay, especially in the more tender seeds. Thus, Kidney Beans, for instance, may be subjected for a time to a temperature of 35° without much injury if they are kept dry, but it is a well-known fact that they will perish almost rather than germinate in soil below a temperature of 45°; hence early crops are generally uncertain. Under these circumstances, and seeing that collections of seeds, even for a large garden, are not very bulky, the best plan is to keep them in a portable cupboard, which can be moved when required and may be found needful in very warm or very cold weather.

GLASSHOUSES AND FRAMES.

CARNATIONS AND PICOTEES FOR WINTER.

The perpetual flowering section of Carnations and Picotees rank amongst the most valuable of winter-flowering plants. Who would not be proud of a bouquet of them about Christmas? Indeed, I have proved most conclusively that from a collection of only three or four dozen plants one can have flowers all the year round. Until recently we had no yellow ground Picotees worth naming amongst the perpetual flowering kinds, and, indeed, until the event of Ascot Yellow and Prince of Orange, yellow ground Picotees were not worth growing; hence they remained in obscurity up to the year 1878. Prince of Orange is far in advance even of Ascot Yellow as regards freedom of growth, and is the only one that I have been able to retain with ordinary care. Its clear yellow, crimson-edged flowers, full and of the largest size, are singularly attractive. In the autumn of 1877, when visiting the Slough Nurseries, Mr. Turner pointed out a batch of seedlings from Prince of Orange which were so promising, that great things were expected of them, and these expectations have been fully realised. Most of the seedlings from this source flowered in 1878, and amongst them are many distinct and handsome varieties, of which the following are the best: Ne Plus Ultra, Sultana, Lady Rosebery, Princess Marguerite, Dove, Ophir, Lord Beaconsfield, Eleanor and Henry Tait.

To have blooms of the best quality in winter, it is necessary to start propagating very early; the small side growths should be slipped off in January; and this applies especially to varieties of the Prince of Orange type, which do not come so early into bloom as the others. Indeed, those raised from pipings about the end of January will not be likely to be in flower until early in the following year. The pots containing the pipings should be plunged in just a little bottom-heat in a forcing pit; they are apt to damp off if covered closely with a hand-light or bell-glass, and are not likely to root freely if quite exposed. I usually place a square of glass over them, which arrests evaporation sufficiently to prevent any of them from shrivelling. Future results will depend on the care and skill devoted to their culture. They must be carefully potted off into small pots, keeping them quite close to the glass when they are in a warm house. The best time for repotting them is when the pots are fairly well filled with roots. The soil should be good, friable, turfy loam, and almost any kind of loam will answer, light, medium or heavy, all of which I have tried with success. Add to four parts of the loam one of leaf-mould and one of rotten stable manure, with a little sand. During summer I place the plants out-of-doors in a sunny position, taking care to fasten the main stems, as the plants advance in growth, to suitable supports. About the end of September the pots should be moved into a greenhouse for the winter. It is not unlikely that the leaves may have become affected with green fly, and if so the plants will not succeed until it is destroyed by fumigating with Tobacco smoke.

The old yellow Picotees are not adapted for borders; rough, wet, and changeable weather in winter would kill most of them. King of the Yellows is one of the best for borders; it is Clove-scented, and is the only pure yellow that has been proved to succeed out-of-doors under ordinary border treatment. Of other colours we have Bride, white; Mrs. Matthews, white; very sweet; Elysian Beauty, rose; Princess Alice, white; Hindoo, crimson; Cremorne, purple; Sentinel, scarlet; Prince Arthur, rich dark purple; Elegant, Coroner, and Fire-eater; all of which are hardy and do not require much care.

J. D.

The Chinese Primula.—This is still one of our best winter and spring flowering plants. We can have it in flower by November by making a sowing about February or March, and then by sowing again in May and July we can maintain a constant supply of flowering plants for the greenhouse and conservatory up to May. I generally grow them in a compost of two parts of good black loam to one of leaf-mould with some dried cow dung well broken up and silver sand added, giving good drainage. Previous to sowing the seed I prepare the pans by watering them and letting them drain for an hour or so before sowing, which renders slight waterings sufficient, as the seeds which are slightly covered are often laid bare by heavy watering. The Primula (single) can be propagated by cuttings, but it is best to grow it from seed. I generally select a few of the best of the old plants when through blooming in spring, cutting out all the flower-spikes and fresh potting them, placing them in a cold frame during the summer, and by potting them on they will make handsome plants by November.—Kirkton.

Japanese Maize (Zea japonica).—This has of late years been largely used as a flower garden plant, and when really well grown in groups it is very effective. As a pot plant for the greenhouse or window it is also worth culture. The seed should be sown in March in a warm frame if possible. When the plants are up pot them on in light, rich soil, and plant out in the open air in June. Seed sown, say in June, would furnish good plants in autumn for the window or greenhouse.

Effects of Lime Water on Plants.—In answer to "Tried One" respecting the effects of lime water on plants, I have used it for many years with the best effects; first, plants only drink when they are dry; if a plant is dry, water it first with pure water, and let it stand for an hour or two, and then you may soak it with lime water as much as you like, and it will pass through the soil and kill all the worms, and not harm the tenderest plant. I gave my Chrysanthemums a good soaking this autumn when I housed them.—Help One Another.

TOWN GARDENING.

DETAILED CULTURE OF PLANTS.

We will now take the most suitable of the plants given in our list last week in alphabetical order, and give the most successful mode of culture for each.

Amarantus melancholicus ruber.—This plant is very useful for bedding; the deep blood-red of the leaves is very effective, especially when the sun shines through them; moreover, it grows very freely. It is about 1 ft. in height. Seed should be sown in a light rich soil, consisting chiefly of leaf-mould and sand, as early as possible, say March, and placed in a steady heat of about 70°. Prick off into boxes when large enough, and keep on growing in gentle heat. The plants are better potted off separately as soon as large enough, lifting them from the boxes with good balls of earth, as they cannot bear to have their roots broken. Harden off gently towards the end of May, and plant out early in June. It may also be sown in a cold frame in April, or even out-of-doors at the end of that month. Plant about 1 ft. apart.

Japanese Maize (Zea japonica)

Asters.—Unlike Stocks, these should not be sown too early; the flowers are not wanted till quite autumn, and the first week in April is quite early enough for them; successional sowings may be made up to the middle of May. The great points in the successful growth of Asters are to give them a very rich soil at all stages, and never to allow the plants to receive a check in any way. They should be treated the same as Stocks, *i.e.*, sown either in a very gentle heat or in a cold frame, greenhouse, or window, in well-drained pans or boxes of light soil; leaf-mould and sand is best with little or no loam. Keep them close to the glass, so that they do not get at all drawn. Prick them out when large enough and getting crowded into protected nursery beds or cold frames, and when good, sturdy plants of 3 in. high or so, plant out carefully with good balls of earth into beds of good, rich, and deeply-dug soil. From 8 in. to 10 in. apart is a good distance for the dwarf kinds, and 1 ft. or more for the tall growers. From

first to last they cannot have too rich a soil, and a bed with a good depth of decayed turf sods and old manure, and a layer of rather fine, light soil, such as equal parts of loam, leaf-mould, rotten manure, and some sand on the top, will grow splendid flowers. They must have plenty of water in dry, hot weather, and, unless the soil is very deep and rich, a good soaking of liquid manure occasionally as they throw up for bloom. Asters need an open and sunny situation. In pots they are very useful in autumn, but it is a difficult matter to grow them so. The only way is to plunge the pots in cold frames or pits and give abundance of air. But it is far easier and quite as good a plan to grow the plants in open borders in the usual manner till the blooms are just opening, and then take up with good balls, having given them a good soaking some hours previously, and put as many in a pot as it will hold. In this way they take no harm.

There are a number of very distinct kinds of Asters, of which the quilled or German, and the French or flat-petalled, are the two great classes, the latter being in our opinion by far the most desirable. The French are divided into the Chrysanthemum or reflexed, and the Pæony or incurved kinds. Besides these are the Victoria, the Emperor, and other kinds having reflexed petals. Nearly every class can now be purchased in tall or dwarf kinds, the former growing to a height of 18 in. or 2 ft., and the latter to 8 in. or 1 ft. only. The tall kinds are very fine for single specimens, or for groups in mixed borders, but for bedding purposes the dwarfs are much preferable. The most suitable for this purpose is the dwarf Chrysanthemum, which makes a most beautiful bed either with the colours arranged separately in bands or mixed. The Victoria produces the most perfectly finished blooms, but what is known as the Pæony Perfection Aster gives us the most handsome flowers, to our taste at least, of any, the shape being very similar to that of the flowers of the incurved Chrysanthemum.

Auriculas.—This is a splendid town flower, as the beautiful plants grown by the Spitalfields weavers can testify. The ordinary garden or alpine Auriculas are the best for out-door culture, as the show kinds are more delicate, and it is usual to grow them in pots. The alpines may also be grown in pots with good results. Hardy Auriculas will stand a town winter better than any plant with which we are acquainted, and will start into growth and bloom early in spring with wonderful vigour. They should have a situation sheltered from the rays of the summer sun at mid-day; at the foot of a north-east or north-west wall is a good place, but the position must not be damp in winter, or they are apt to rot off. The best soil for them is a rich loam, but they will grow well in almost any good garden soil. After they have bloomed, and it is well to give them some protection from east or biting winds when in bloom, take up the plants, remove the young suckers, and plant them separately; either plant the old root again right up to the leaves, or throw it away. But if you can afford the plants the shelter of a frame, far better results can be obtained by growing choice sorts in pots. Either the alpine or show kinds, or both, may be thus grown, and neither of them require any artificial heat at any season. The show kinds are more delicately beautiful, but they are not so hardy or free flowering as the alpines. Both require as nearly as possible similar treatment. The main thing is to give them plenty of air and light, and never let them flag for want of water; yet they must never be too wet, especially in winter and about the stems, as they are rather apt to damp off there. The best soil is a good rich fibrous loam, with a small proportion of very old manure or leaf-mould, and a little sand if needed, but if the loam is not very stiff it is better omitted. Four and a half or 5-in. pots are quite large enough for single plants; pot them pretty deep—up to the healthy leaves, all dead or decayed portions being removed, and rather firmly, but not too much so. The best time for potting is when the offsets that form after flowering are well developed and rooted, so that these may be removed and potted separately at the same time. This will be about July, the plants having been well exposed in a shady place from the time flowering is past. Pot the suckers, if at all small, in 3-in. pots, and shift them on into 4½-in. or 5-in. when ready. After potting, place the plants in a frame under a north wall, so as to be in the shade, and keep them close for a few days, till the potting is recovered, then gradually accustom to plenty of air, and in September remove from the shady place to their winter quarters, which should be a Box frame facing full south. This should have a raised stage or shelves arranged within it, so as to keep the plants off the ground and near the glass; if there are doors or movable boards at the bottom that can be removed to admit air from beneath, all the better. The plants should be stood in this and the lights kept tilted, so as to admit plenty of air, and removed for an hour or two on fine mornings and evenings altogether. Be careful how you water them, and in doing so be sure not to let any get on the leaves; remove all decayed leaves as soon as shown. Only admit air from the bottom when the weather is fine and warm. Shut up close on frosty nights, and in severe weather mat up well, and keep all close as long as the frost lasts; and for delicate show kinds it is well to bank up turf sods all round the frame, to keep out severe frost. In February take off a little of the top soil, pricking it up with a pointed stick, but not disturbing the roots, and replace with some fresh compost, made pretty rich. This is called "top-dressing," and is a great assistance to the plants; it should be done when the soil and pots are dry. Give weak manure water twice a week when the flower-buds appear, and remove any green fly that may appear with a camel's-hair brush. Shade from hot sun, and remove to a shady place by the end of April, still keeping in the frame. After flowering, which takes place in April or May, remove the plants from the frame, and stand or plunge out-of-doors under a north wall, or east will do nearly as well, and let them remain here till potting time comes round again; it would do just as well to withdraw the light and leave them in the frame. Keep them rather dry in winter, especially in severe weather. In potting off the offsets, if they are small, put three or four round the sides of a 4-in. or 5-in. pot, and if they have no roots at all use sandy soil, put three or four in a pot, and keep under a hand-glass or in a cold frame close till rooted. Seedlings make good plants. The seed should be sown in pans of loam, leaf-mould, and sand early in spring, and the pans placed in a cool frame or greenhouse, and kept moist and shaded. When well up and large enough, prick off separately into boxes or pots, four in a 5-in. pot. Pot off separately about September. The plants will nearly all flower in the spring following. There are a great number of fine named kinds which are preferable to seedlings where expense is not an object. A few of the finest are—

Alpines.

Balsams succeed well in a smoky atmosphere. They may be grown either in the open air or in pots, but as we are now treating of out-door gardening we only give the mode of culture in the open air here. The seed may be sown either in pots or boxes under glass, with or without artificial heat, or in a sunny window after April 1, or in May in the open border. For seed-sowing under glass use leaf-mould and sand, with a little loam mixed with it. A gentle heat will cause the seed to germinate more quickly. When the plants have formed the first pair of rough leaves, prick off into deepish boxes, frames, or protected nursery beds, and when strong transplant with good balls to where they are to flower. If sown late in the season out-of-doors, make the soil deep and rich, and merely thin out and transplant as needed. The soil for Balsams can scarcely be too deep, light, or rich, and they should have abundance of water at the root, and frequent syringings overhead. This is of great importance. A good soaking of liquid manure once a week when the plants are coming into bloom is beneficial.

Calceolarias (Shrubby).—These are very showy and useful. Where a number are required the best way is to take off nice young side shoots with a slight "heel," and trim them neatly, removing the leaves half way up the cutting. The best time for striking them is October, not too late in the month if the weather is very cold. Set a small frame on a piece of ground facing south and in a light and airy position; put a few inches of broken bricks, or "ballast," which is clay burnt in the rough, and is frequently used as a substitute for gravel—it makes capital drainage for pots or boxes; put a few inches of this or other draining material in the bottom of the frame, then a layer of old hops, decayed, and on that about 4 in. of fine sandy loam, with only a little leaf-mould in it. This should bring the surface of the soil up to 8 in. or 1 ft. from the glass. Make holes in rows with a dibber about 2 in. apart, put a little sand in each, and plant your cuttings, pressing them pretty firmly into the soil, but not making this too hard. Then give a good watering from a fine-rosed pot, and put on the sash, leaving the frame pretty well open till the cuttings are dry; then shut up close, and only give a little air for an hour or two on fine days. Cover the frame well up with mats or sacks in frosty weather, especially at night, when the frost is very severe; and if it is very hard, a good layer of grass sods packed closely round the sides of the frame is a great help, but it should be done before the frost sets in. Little or no water should be given until the plants begin to grow, but do not let the soil get very dry. They will not make any roots for at least a couple of months; but as soon as they have done so, and show signs of growth in spring, give a little air when safe, and as the weather gets warmer and the plants advance give more, and harden as much as possible. When they are nice, strong, bushy plants, say in April or early in May, lift them separately with good large balls of earth (having given a good watering previously), and plant where they are to flower. If they have all rooted and grown well, so as to get at all crowded before planting out time, take out every other one and either pot or plant in a cold frame 6 in. apart. In this way you will get far healthier plants than by any other method. These plants need no fire-heat, though we have sometimes put a large jar of hot water in the frame on very severe nights; the ground in which they are to grow should be well dug at least 18 in., and if 2 ft. or more all the better, and plenty of good manure should be worked in, especially deep down. In this way they will keep on growing and flowering all through the summer, and not go off as they often do in shallow soil. Where only a few plants are wanted, they may be struck in wide boxes or pots, in which case it is better to take the cuttings rather earlier, and frost should be kept away during the winter. Cuttings may be also struck in spring—March or April, but a gentle heat of about 70° is requisite to induce them to form roots at that season.—B. C. R.

Uses of Lime in Gardens.—Culinary vegetables, and even fruits, are finer in quality, more robust in constitution, and better coloured when grown in soils that have a proper proportion of lime in their composition than when grown in those where it is very deficient. Its application in the garden is, moreover, no less beneficial for the destruction of plant-devouring slugs, injurious insects, and the unsightly growth of Mosses and Lichens; for all of which purposes the late winter and spring months are those in which it can be best and most beneficially applied. The ground being cropped in summer, it cannot be spread and covered in with facility unless in exceptional cases, such as between the clearing away of early and the sowing or planting of succession crops; if deferred till autumn, it becomes diminished in action from being washed and wasted during the immediately succeeding dull and rainy period of the year. Yet even in early autumn few would begrudge a good substantial top-dressing of quicklime to their Strawberry plants, if they were aware of the havoc which it makes amongst the slimy broods of the worst fruit-destroying nuisances during a rainy season. To

check snails and slugs in time, commence soil-liming with the sowing of early seeds, when the days are sunny and the earth sufficiently dry to allow of working among the soil with freedom. Use hot or quicklime liberally, merely hoeing, raking, or pointing it in on the surface; give good coatings of it also over Strawberry drills, by Boxwood edgings, the sides of walls, and on other vermin-harbouring places; renewing surface dustings frequently afterwards, when it becomes washed away, saturated, or inert. Nor should the extirpating effects of lime, or lime water, upon worms pass unheeded, when they disfigure the surfaces of fine grassy lawns and bowling greens with their unsightly earthy outcasts; or when they abound among small recently-planted seedlings to such an extent as to cause their destruction by turning them out of the earth and by drawing them into their holes.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

November 29.—Sowing Nemophila in pots; also four lights of Radishes and Carrots on a leaf-bed; manuring and rough digging vacant ground; beginning to dig flower garden borders; putting "show" Pelargoniums into their flowering pots; putting a little Moss to plants of Odontoglossum coronarium which are just pushing out new roots; putting into force Cinerarias, Anne Boleyn Pinks, Roses, and Dielytras; protecting Celery ridges with litter when frosty; washing Camellias in conservatory; putting soil into Seakale shed to warm for French Beans; hoeing among Strawberries and other crops, such as Cabbages, Lettuces, and Onions.

Nov. 30.—Planting Raspberry canes, giving each two forkfuls of manure; putting herbaceous Calceolarias into their flowering pots; also Asparagus on bottom-heat every fortnight, and Seakale every week; shifting plan s of Schizanthus into 10-in. pots, and staking them; giving orchard house a thoroughly good watering and a top-dressing of manure and loam.

December 1.—Trenching border for Roses; finishing the planting of fruit trees; planting a new Mint bed; making a new Mushroom bed; giving air to all Orchids as soon as the fire begins to raise the temperature of the house well above night heat.

Dec. 2.—Sowing Mignonette in pots to come in in April and May, also Cucumbers, Mustard and Cress regularly, and 500 pots of French Beans; shifting some late Primulas into their flowering pots; getting Pea stakes, fumigating Orchids and Cucumbers, sponging Palms.

Dec. 3.—Potting Pleiones in good peat; shifting a few small Palms for dining-room and other kinds of decoration; planting Yew trees and Junipers in the pleasure-ground and guarding them with wire protectors to keep off rabbits; plunging some Hyacinths on bottom-heat in Vinery, also Lily of the Valley. Miscellaneous—Putting in more Asparagus to force, which, if kept at 65° by night and 70° by day fire-heat, will be ready for use in from sixteen to eighteen days; nailing Plum trees on walls; finishing pruning Green Gage Plum trees.

Dec. 4.—Taking up Ghent Azaleas for forcing. Potting Ashtop Potatoes and placing them in heat; giving Lilacs and Briers in Pots a top-dressing of manure; pruning and tying up pillar Roses; pruning espalier Pear trees and saving grafts of any kinds that are required; cleaning lawns of leaves and worm-casts, and rolling them well and often.

Flower Garden.

At the present season, the one special requirement in flower gardens and pleasure grounds is, as has been previously stated, the maintenance of neatness. Keep clean, firm walks, smooth turf, freshly-pointed flower-beds and shrubbery borders. No labour should be thought too great to attain this end. Of course, where there are many deciduous trees, the fallen leaves will for the present retard the extreme neatness here alluded to, but as soon as all are down, rake out every corner, or the first windy day will blow them just where they are not wanted, and tell tales of work only half done. If the weather prove open and dry, shrub and tree moving and planting may still go on; to plant under any other conditions is simply wasted labour, for the commonest tree or shrub fails to thrive if planted whilst the soil is pasty; the reason is not far to seek—the spongioles and breathing pores of the roots are, as it were, sealed up by compression of the sodden soil about them when planting. Contemplated alterations and improvements should at once be decided on, and undertaken whilst there is time for such labour, without neglecting work which, as the season advancies, requires to be done. Soil, vegetable mould, and manure should also now be got together for enriching the beds in spring, and also for potting bedding plants; these latter will require careful attention as to watering, till daylight and a drier atmosphere are on the increase.

Auriculas.—It matters little how keen the frost may be if the leaves of Auriculas are dry, but frost acting upon plants through the glass causes the leaves to be covered as it were with a thick hoar frost. It involves a little trouble to throw a single mat over the glass, but it is desirable to do this rather than the plants should suffer from damp caused by the frost. Still continue to admit air freely when the weather is dry.

Carnations and Picotees.—Plants that have been placed out in cold frames require much the same treatment as that recommended for Auriculas. Admit air freely and see that there is no drip over any of the plants. The old stools that have been placed in a cool house are looking well, but the dry atmosphere is causing green fly to increase on the layers, even while they are in a temperature but little above the freezing point. For this fumigation must be resorted to.

Hollyhocks.—Where these have been recently potted, many of the leaves continue to decay, and it is quite necessary that they should be removed without delay. It is also a seasonable time to see to the old stakes that have been used. They may be cleaned and stored away neatly in a dry place, and any that have decayed at the base may be cut shorter, to be used next year for Dahlias, and new ones may be prepared for the Hollyhocks. In many places good stakes can be obtained in the woods from the cuttings of tall brushwood. The growths of stools of Ash or Hazel cut over when about 10 ft. or 12 ft. long answer well for stakes; but where these cannot be obtained, they may be made of 1¼ in. deal cut into strips, the corners planed off, and the stakes painted green, except that part under ground, which should be painted with a mixture of equal parts boiling tar and pitch. We have had stakes last for ten years when they have been painted in that way.

Pansies in Pots.—These are never at rest during winter when the air is above freezing point. They do not require very much attention, except to see they do not suffer from the attacks of green fly. They should now all be in their flowering pots, and as these are not well filled with roots, care must be taken not to apply any water to the roots unless the soil is fairly dry. Give air to the frames freely, but shut them up early in the afternoon if there is any sign of frost, and cover them with mats at night.

Forcing Pinks.—Those who have not yet grown these useful plants for forcing have a treat in store. We have potted ours and hope to have a good display. The best position for them now, next to a shelf in a cool greenhouse, is plunged amongst dry Cocoa-nut fibre refuse in a cold frame facing the south. The plants require moderate supplies of water, and the pots must be kept quite clean.

Polyanthuses.—It is not necessary to give these treatment at present very different from that given to Auriculas. Keep the lights over them in severe weather, but give air freely whenever the weather is dry. See that none of the plants suffer from want of water at the roots, and keep green fly off the leaves by fumigating, but be careful not to over-do the fumigation, as the leaves are easily injured.

Shrubbery.

The digging of shrubbery borders and plantations is of the utmost importance in assisting the growth of trees and shrubs; it mellows and sweetens the soil, breaks up the haunts of many injurious insects, and gives a neat and clean appearance to the borders. Dry weather in November and December is the most suitable time for this work, as then most of the deciduous trees and shrubs have shed their leaves. Shrubberies which have herbaceous borders surrounding them should have the Grass edges neatly cut, and the borders cleaned and mulched where necesssry; all stools requiring it should also have suitable protection from frost. Where no such borders exist the shrubs may with advantage be allowed to grow over the turf, and in no way should the latter be interfered with. Prune trees and shrubs requiring it, rearrange others, or take them out altogether if needful, in order to give plenty of room for the better varieties. Although it is very necessary in towns to plant liberally, care should be taken that the best trees and shrubs, especially those which are in the best positions, do not suffer from overcrowding; it is far better to secure a few fine trees and shrubs than a large number of weak ones, and by no other means can a park or open space become thoroughly and properly established. Much damage is done by neglect and carelessness in the matter of thinning out at the proper time because of the imaginary sacrifice; this is false economy, however, and should be carefully avoided. Steel forks are the most useful tools for digging amongst trees and shrubs, except in very light soils, spades being much more likely to damage the roots; whatever kind of tools are used, however, care should be exercised in order to keep a sufficient distance from the stems to ensure their safety.

Fruit.

Where the good old practice of applying surface mulchings of manure to all newly-planted trees is carried out, there need be no fear of the weather in any way proving injurious to them. Those who have not yet so dressed fresh-planted, or recently root-pruned trees, should take the first opportunity of doing so, for such a dressing not only acts as a fertiliser, but excludes frost, and the ground being thus kept warmer, fresh root action is the sooner induced. Nor is the application of such surface manurings alone beneficial to newly-planted trees, but to all fruit trees that are in any way exhausted by overproduction. As a rule, it is best to pull up and destroy old and decrepid trees, and to replace them with young ones; but, at the same time, it is well to distinguish between decrepitude and those that are only suffering from want of assistance to re-invigorate and start them as it were into new life. All such trees should have the old soil removed right down to the roots, and new compost, consisting of good fresh loam, bone manure, and charcoal, or wood ashes added, and afterwards a good surface dressing of rotten manure should be given them. We never fail in giving Strawberries and Raspberries such a manuring every autumn, and the results are heavy crops of fine fruit. The temperature of the ground being now about at the minimum point, and growth in fruit trees suspended, any planting still on hand would be better deferred till growth again commences in February. Meanwhile, whenever the weather is favourable push forward all such operations as pruning, training, nailing, and tying. All kinds of fruit trees, with the exception of Peaches, may now be operated on. It is a very difficult matter to lay down a rule as to how, and to what extent, certain trees should be pruned; but the following may aid those who are in doubt through lack of experience: First, then, if a tree has grown extra vigorously, there is a disposition to use the knife proportionately freely; but this only tends to aggravate the evil. The strongest growers must have the lightest pruning, and the vigour must be repressed by working down amongst the roots, and cleanly cutting off what are commonly called "tap roots," *i.e.*, roots that have developed a perpendicular form of growth without throwing out side-rootlets; when these are severed the trees become more fruitful and less productive as regards top growth. Trees that make but moderate or poor growth may, if necessary to get them into shape or form, be pruned hard without danger of evil consequences; but, generally, such trees require but little pruning, particularly if at all subjected to summer pinching or stopping, which, after all is the most rational mode of pruning, or, rather, it is a process which renders pruning unnecessary. Apples and Pears will by this time have become inured to the temperature of the fruit room, and therefore "sweating" will be over. The ventilators should now be always kept closed, except for an hour or so at mid-day, when the weather is fine and mild. Examine the fruit frequently, removing any that are decaying, as the fungus spores from these spread to others with great rapidity.

Vegetables.

Globe Artichokes.—These should now be protected; if, after the heads were used, the old stems were cut away, the young growth at the bottom will be in a robust state, capable of enduring even the most severe winter with a little protection. The best material is about 1 ft. of dry litter placed lightly round the young shoots, but not over them, leaving the largest leaves just above the tter; round this place

9 in. of soil two-thirds as high up as the litter, in the form of a slight Celery ridge, but not drawn up so close. Where the rows are near together it will be necessary to bring the soil from elsewhere. In this case coal ashes, if at hand, will answer the purpose in every way.

Early Peas.—Those who reside in districts where severe and protracted frost is not usual, and where, in addition, the soil is of a light nature, may now sow a few early Peas for the chance of having some a little more forward in the season than by later sowing. Choose a situation sheltered from the north and east winds, with the ground, if possible, sloping to the south. Dig it well, and mark out the rows 4 ft. apart; in opening the ground for sowing do not go above 2 in. in depth, for if the Peas are put in deep at this season, they are liable to rot. Sow considerably thicker than would be required in spring to make up for such as may not vegetate, or that suffer from the attacks of slugs; cover with the soil in the usual way, and over the top put a couple of inches of fine coal ashes. This will not only act as a protection from frost, but also prevent slugs from penetrating the ground and devouring the young sprouts as they are pushing up through the soil. On ground that is much infested with slugs there is great difficulty in keeping these early-sown Peas from being eaten, and if, in addition, the soil is of a wet retentive nature it is better to defer sowing until January.

The Water Soldier (Stratiotes aloides).

The Water Soldier.—This is one of those curious water plants which are seldom seen except in the gardens of those who have collections of aquatics. It, however, frequently becomes naturalised in ponds and waters, into which it has been introduced from the garden, and it is believed to be really wild in the fens of eastern England, in Ireland, and in some parts of Lancashire and Cheshire. Our illustration shows both the plant and the flowers well, though it can scarcely be called an ornamental plant in the common sense of the word. Nevertheless, it possesses some interest for lovers of hardy water plants, and it is easily established in any piece of water, small or large. Its botanical name is Stratiotes aloides, the specific name being given from the resemblance of the plant to some Aloes. In the autumn the plants sink to the bottom of the water. In the spring, from among the leaves of the old plants, arise numerous thick suckers, which produce young plants. The flowers are like those of the Frog-bit, pure white with yellow stamens, and they appear late in summer. The leaves are saw-edged and from 6 in. to 18 in. long.—W.

Trumpet Creepers.—Among the hardy climbers that deserve high rank are the Bignonias, or, more properly, Tecomas. Their rapid growing, woody stems, bright foliage, and richly coloured flowers have acquired a well-deserved reputation for beauty and practical qualities; but their very vigour, a good trait in itself, may become a nuisance unless checked and trained by systematic pruning. All species of Tecoma possess both beauty and vigour, but in the quality of hardiness a decided distinction should be made. They come from all parts of the globe, and their habits vary accordingly; but my object at present is to notice only one variety of a certain hardy species. T. radicans is the hardiest and best known of all, and is only surpassed by grandiflora, because of its grander and more open flowers; in hardiness, the latter is decidedly inferior. T. radicans shows a bright red colour, and a narrow, straight form of the trumpet-shaped corolla, quite peculiar and distinctive. In date of blooming it differs but little from T. grandiflora, and otherwise comports itself like a near relative. There is, however, a variety of radicans called sanguinea præcox, the superior qualities of which have received slight recognition. Several nurseries of this country offer in their catalogues a variety of radicans variously termed sanguinea, atro-sanguinea, and coccinea. I suppose this to be the same as the one to which I refer, although our name comes from Belgium. Garden varieties are frequently somewhat mixed, and botanists give but little attention to the adjustment of the names of these minor forms. I select the Belgian name as more descriptive, and hence much better, especially as those of our catalogues fail to mark two distinctive peculiarities of the climber in question—namely, that it excels all others alike in early blooming and rich colour. While grandiflora and radicans bloom in August, sanguinea præcox commences to display its deep red flowers early in July. This extension of the season wherein we may look for flowers on the various species of climbers is of much importance to those wishing to increase the number of floral effects on their lawns at any given period, especially when that period is not prolific of flowers, as is the case in July. This is a good time to plant, or the ground may be prepared ready for planting in March. The early variety mentioned above would probably be more valuable than the older forms in our gardens.

FRUIT.

FRUIT TREES FOR HIGH WALLS.

The value of what is known as the upright system of training fruit trees is not sufficiently known. Wall culture is necessary for the production of the finest fruit in many northern and temperate climes. We seem to have long recognised this fact, but not to a sufficient extent, and the progress with wall-fruit cultivation is very slow. Not in one garden out of ten is sufficient attention paid to it, while it is most rare to find the walls of gardens in which considerable pains are taken with the fruit trees covered as they ought to be. We will assume that the cultivator is sufficiently aware of the importance of walls in the production of the very finest fruit, and that he has selected the varieties really worthy of culture in this way. After these there is a third condition of success indispensable to perfect wall culture, the absence of which leaves half our wall surface bare and robs us of quantities of the finest fruit. This is the true mode of covering walls quickly and well—the erect training. The wrong and the tedious, and therefore the profitless mode, is the large fan or horizontal tree, which takes a dozen years to form well even in good hands, and perhaps by the time it is formed some new varieties will have come to light, and the judicious cultivator will be anxious to clear away the results of so many years' work.

There is no need to spend even one-third of this time in the covering of even the highest garden walls with forms of trees as fruitful, as agreeable to the eye, as any of the old large forms, and much more easily made. The simplest and best form for every kind of wall fruit is the erect one, with from one to four or five branches ascending from the bottom to the top of the wall. In this way a good cultivator, by selecting healthy and vigorous plants to begin with, may furnish a wall 10 ft. high in two years from the time of planting.

To do so, he would not, of course, follow the common practice of cutting hard back the shoots; if he thought they would not break regularly, he would bend them down to induce them to do so. With good young trees, three years are the most that should be required by any gardener to cover the wall by this system. It must not be supposed that it is applicable only to the Pear; it is equally so to every other kind of fruit tree worthy of a place against a wall. In the case of the Peach a still smaller form is, we are quite certain, desirable. A Peach tree with two branches like a capital U may seem awkward to persons only accustomed to the fan mode of training; but we have seen many walls perfectly covered by it on the Continent, and it is far better suited to our climate than a larger form. Trees trained in these particular forms are not required to begin with; we have simply to take, in the case of the Pear or the Apple, a young nursery tree, with its five branches or so, and train four or five of them, as may be required, in a vertical manner against a wall, and at equal distances.

The general adoption of this system would soon fill our fruit rooms and cover our half-naked walls. It would prove of the greatest possible advantage to gardeners generally, in enabling them to rapidly cover the many bare walls one sees; and if a desirable system for ordinary garden walls, it is much more so for the walls of stables, houses, &c., which it takes years to furnish by the common plan. The only case where it is not so suitable as a spreading mode is on very low walls and trellises.

Examples of walls as well covered as those shown in our woodcuts are not unfrequent in France and Belgium, and we have seen a very good example of growing the Apple thus with Mr. Sage, in the garden at Ashridge Park, who covered a portion of his walls in two years with choice dessert Apple trees. At Chiswick similar methods of training have been carried out with the best results.

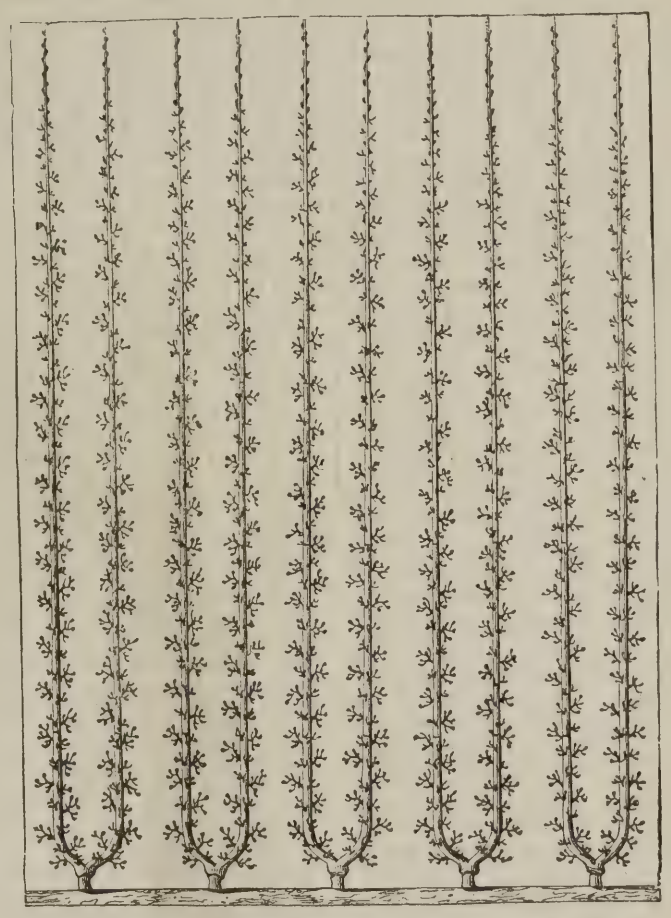
Keeping Fruit.—A few principles are important in keeping fruit, particularly Apples. The first is coolness of temperature. If too warm, they (the Apples) will mature, so that temperature is the important thing. Keep as cool as possible for long keeping. A little frost, gradually let out, does not seem to hurt. A low

uniform temperature, say at 40° or a little below, just avoiding the frost, is all that is wanted in the line of temperature, so far as Apples are concerned, and other fruit comes under the same general head. It is no difficulty to keep this point in the winter, only be sure and have your cellar or fruit-room warm enough to withstand the heaviest cold. If in the warm days there is a tendency to too much warmth, open the windows or doors; do not neglect them. The next great consideration—and it is almost equally great with the first—is the hygrometric condition. If too moist, you may be sure your fruit will rot—will mould. If too dry, it will shrink—that is, lose its moisture—and this is almost as bad as rotting.—W.

Best Strawberries for Different Purposes.—I grow successfully the following Strawberries for different purposes, and can confidently recommend them, viz., for early forcing—Early Prolific, President, and Sir Joseph Paxton; for late forcing—Underhill's Sir Harry, Cockscomb, and James Veitch; for general purposes—Early Prolific, President (which in my light soil bears enormously, and is unique in flavour), Sir Joseph Paxton, Unser Fritz, and Rifleman; for jam—La Constante and Jeanne Hachette; for fruit-ices and punch—Belle Bordelaise, Royal Hautbois, Black Hautbois, and Red Alpine; for purposes of exhibition—Unser Fritz (perhaps the noblest of all Strawberries), James Veitch, Cockscomb, Dr. Hogg, President, and Sir Joseph Paxton.—E. N.

Keeping Grapes in Bottles.—Placing bunches of Grapes in bottles of water to preserve them during the winter is a system often practised, and under certain circumstances it possesses many advantages. In Vineries full of plants, and where there are many Grapes hanging, it is impossible to keep the atmosphere sufficiently dry to prevent the fruit from rotting, and in such cases it is much better to cut the fruit and bottle it than to let it spoil on the Vines. Many old Vineries, too, are far from being waterproof, and, consequently, ill adapted for keeping Grapes. Moreover, where there are only, as often happens, a few dozen pounds of fruit hanging in a large house, from which it would take a great deal of firing to keep out frost and damp for any length of time, cutting and bottling may be profitably resorted to. In cutting bunches for this purpose from 4 in. to 6 in. of the shoot between the main stem and the bunch should be removed along with the fruit. This piece of wood is placed in the mouth of the bottle, which may either be laid down in a slanting direction, so as to allow the bunch to hang over the edge of the shelf or whatever else may be best. Pint bottles suit most bunches, and they need not be quite filled with water; on the contrary, if the end of the shoot is covered that is sufficient. In order to prevent too much water from passing through the wood, the cut end may be half charred before it is placed in the water. A fruit room in which Apples and Pears keep well is a good place in which to put Grapes bottled in this way. The atmosphere about them should be kept dry, and the temperature should not be allowed to fall below 40°. They should also have air and plenty of light on all favourable occasions. Under this treatment few berries will decay, and their flavour will not deteriorate much. Grapes may also be kept by cutting the bunches as if for bottling, and running the cut end of the wood into a fresh Potato. Thus circumstanced, they may be hung up in a room like that to which reference has just been made. This plan is, however, not so good as bottling. When the bunches are cut for these purposes, the Vines should be pruned at once, and all cleaning required should be done. Grapes need not be cut merely for the purpose of relieving the Vines, which do not suffer through fruit hanging on them, even until the buds begin to swell the following season.

Mosses and Lichens on Trees.—Even admitting that Mosses are harmless on fruit trees, they are nevertheless unsightly when thickly dispersed, in luxuriant growth, over fruit tree and bush stems and branches; and we would as soon think of allowing the growth of gross weeds among fine flowers as that of these epiphytes on what are expected to be fruit-laden boughs. They are quickly destroyed by lime applied (though hot lime may not extirpate many of the numerous insects) just before the buds begin to open; then, on the morning of a quiet day that is likely to continue dry and sunny, syringe over all the branches with water, or, better still, with soap-suds, till they are thoroughly wet, then dust on the hot lime till no portion remains unwhitened. Should the weather actually continue dry through the day, and no deluging rain fall immediately after, the lime will adhere for a considerable time, and no renewal of it need be made till next year. After this application the Mosses and Lichens will wither up and crumble into dust, and become dispersed, together with any insects or insect ova that may be associated with them, by the first fanning wind, or by their own gravity, light though they be, so as to leave the bark clean and smooth where before it was foul and rugged. If the application of lime to trees and bushes is made too early, it is liable to be washed off before the sun becomes sufficiently powerful to impart its full share of burning influence; while, if delayed till the young leaves and blossoms begin to protrude, these are liable to get somewhat browned or scorched: hence the propriety of choosing the time before mentioned for applying it.



Method of training Pear trees to quickly furnish high walls.

ANSWERS TO QUERIES.

3530.—**Christmas Roses.**—Helleborus niger is one of the best and easiest of herbaceous plants to cultivate if "C. B." will prepare a bed 18 in. deep, trench in or fill up with good rich loam, old mortar rubbish, or small quantity of good sharp sand, secure good strong plants, after planting do not disturb them, only keep the surface of the soil from becoming sour, attend to watering in the spring while they are making their growth, place over them when frosts commence a good frame, and give all the air possible during good weather. Under this treatment I have had plants to produce over 100 blooms in one season, and at a time when flowers are much required.—T. Lowe, *Penketh.*

3644.—**Unsatisfactory Vines.**—There would seem to be little doubt from the description given by "J. R." of his Vines, that they are affected with mildew. Their having this disease, and also the fact of their putting forth air roots, appear to indicate that they are suffering from their proper roots being in a cold, damp situation, they having probably worked downwards into an uncongenial subsoil. The branches have also, most likely, been deprived of the ventilation necessary for their healthy growth and development of leaves and fruit. An old Vine of mine, trained in a greenhouse, roots outside, which had, season after season, been attacked by mildew, was effectually cured, and has remained ever since quite healthy by simply trenching round the roots to a depth of about 2 ft., half filling the trenches from the bottom with rubble, and the upper portion with garden mould. This remedy would probably prevent air roots also. Since, however, "J. R.'s" border was re-made last year, perhaps he had better lift a portion of the roots of each Vine this winter, and spread them out near the surface, doing the same with the remainder the following year. This, and a proper attention to ventilation and the avoidance of over-cropping, will probably remedy what he complains of. He might also, with advantage, paint the Vine stocks and shoots after the winter's pruning with Gishurst Compound.—J. M., *South Hants.*

3578.—**Passion-flower not Blooming.**—We can only surmise that the plant in question has not attained sufficient vigour, or that the wood has not ripened well enough to admit of flower-buds forming. If the plant is a large one, and the branches have become at all crowded, we would cut out all the weakly ones, laying in the strongest at wide intervals, shortening them back to two-thirds of their length. Each young shoot will then come away strong, and if allowed ample space to develop, should mature sufficiently to give bloom. During the growing season give plenty of water in hot weather, and take care to frequently syringe overhead. The

Passion-flower likes plenty of light, heat, and moisture when growing, enjoying at the same time a free circulation of air, without which the tissues do not harden sufficiently to admit of the wood coming into a bloom-bearing state.—J. CORNHILL.

3609.—**Vallotas not Flowering.**—We should imagine that the plant in question was shifted into unsuitable soil, perhaps of too tenacious a nature, the consequence being that the fleshy roots have got into a partially torpid state. Water just enough to keep the foliage green until April, and then, after allowing the soil to become quite dry, turn the plant out of the pot, and if the points of the roots appear at all black and decayed, work away as much of the soil as possible with a pointed stick, and replace in the same sized pot, filling in with fine, light, well-sanded compost. Place the plant in a light, airy greenhouse, frame, or room, and give plenty of air when the weather is favourable. The Vallota does not like confinement in any shape; it is almost hardy in our climate. Water moderately until the pot gets full of roots, and then give more copious applications.

3645.—**Deformed Cyclamen Blooms.**—Instances may be found of Cyclamen plants which appear incapable, in spite of the best of treatment, of bearing anything but imperfect flowers. In such a case there is but one remedy—that of throwing the plant away. As a rule, however, deformed blooms are caused by imperfect root action, or by the attacks of green fly in their bud state. The insect finds its way into the petals as soon as they emerge from the calyx, and, sucking the juices from them, cause them to twist in their development, or quite hinder their progress. Plants which have been grown in a close atmosphere are especially liable to the attacks of insects, those which enjoy a free circulation of air during the summer months, and full exposure to the night air when the weather will permit, as well as to the sun's direct influence during the autumn months, being but little affected by insect plagues, for the plants appear to become so hard and vigorous, that the green fly does not find the young leaf or bud at all to its liking. It is also to be noted that the roots of plants thus grown are far more lively than is the case when growth has been made in a more confined atmosphere, and will consequently admit of being more copiously watered, with the consequent effect that good-shaped blooms are formed. Where fly exists, and this is easily seen, the best plan is to dip in Tobacco water, at the rate of 4 oz. to the gallon, but to make certain of eradicating the pest two immersions at an interval of a week will be necessary. I should also add that any check experienced, such as too much water or too little when the buds are forming, will cause deformed flowers, and as the buds are formed successionally for a period of three months, it may easily happen that some flowers come imperfect and others of good shape. Our advice is to place the plants in a cool house, give plenty of air, and water carefully; the after flowers will then in all probability come as they should do.—J. C., *Byfleet.*

3567.—**Raising Australian Plants from Seed.**—The seeds may be sown either in March in gentle warmth, to be removed when fairly up into a cool structure, or they may be sown in a cold frame about the latter end of April. Prepare some 4½-in. pots by well draining them, and fill them to within 1 in. of the rim with fine, well sanded peat, to be made quite firm and level on the surface. Then water gently, and when superfluous moisture has passed off, sow the seeds thinly, and cover with very fine sandy soil. Then cover with a pane of glass, shading the same with a piece of paper until the young plants appear above ground. When they are large enough to handle, they may be pricked out in pans or 6-in. pots, and the following year they should be potted into small pots. A cool greenhouse will suit them very well, keeping rather close when first potted, but giving plenty of air during the summer. A cold frame will be even better than a greenhouse, but they must not get frost-bitten.—J. C. B.

3646.—**Planting Gooseberry Trees.**—Although it is well to trench the soil 2 ft. deep before planting any kinds of fruit trees, it is not advisable to highly manure it, as it tends to the development of gross, rank growth that is not fruitful. If the soil be fairly good, that will suffice for any fruit tree; but in planting, having first shaken in some fine soil about the roots, add a little manure before finally filling in. This will help to exclude severe frost, and promote a surface development of root growth. Then, in future years, by the addition of surface dressings of manure, the trees may be kept robust and fruitful. One of the dangers incidental to planting in rich, deeply stirred land is, that strong main roots are encouraged to go deep, where they soon find a sour soil. When this results the only remedy is to root-prune; if, however, a little judgment be shown in the planting, this necessity may be avoided. Gooseberry bushes scarcely need root pruning in any case, but the more the roots are encouraged to the surface by top-dressings the more fruitful will the bushes be.—C.

3662.—**Out-door Tulips.**—Tulips, as a rule, bloom naturally in the open air in the month of April, and not in March. The earliest are the Van Thols, but these have the smallest flowers, and are more transitory than are the later ones. The best, because most massive, are the doubles; these endure longer, but need some support if the weather at blooming time be wet and stormy. The best six double kinds for out-door culture are La Candeur, white; Marriage de ma Fil, red; Tournesol, yellow; Rex Rubrorum, dark red; Murillo, rose and yellow rose. Six good single kinds are Yellow Prince, Rose Grisdelin, White Pottebakker, Kaiser Kroon, red and yellow; Proserpine, rose and violet; and Rosa Mundi, tinted white. All of these grow to a height of about 10 in., and are fairly even, making rich, beautiful masses. If these be planted in a bed of some neutral-coloured carpet plants their effect is much enhanced.

3663.—**Zinnias.**—The richest soil will, with the Zinnia as with the Aster, produce the finest flowers. The Zinnia will transplant freely from the seed bed, but a considerable check is given in such cases. The best plan is to sow a couple of seeds in a small pot, and take out the weakest when the plants are well up. This may be re-potted into other pots, and the check will make them become a succession to the others. When these plants are 6 in. high they may be planted out in rich garden soil 15 in. apart, and at blooming time, if needed, the smallest flower-buds may be cut off, leaving only the finest to produce flowers for exhibition. Their quality largely depends then upon the quality of the strain of seed.—A. D.

3665.—**Rabbits Gnawing Forest Trees.**—If Gishurst Compound at the rate of 8 oz. to the gallon be dissolved in soft water, and sufficient clay added to make it of the consistency of paint, and if it be then applied to the stems of the trees, no rabbits will bark them for the next year to come. Of course no application of the kind will be of much longer duration. The compound can be obtained from any seedsman.—E. H.

3643.—**Draining a Garden.**—To drain a piece of land where there is no outfall is a difficult matter. A ditch across the lowest end 3 ft. or 4 ft. deep would answer the purpose with a drain down the centre of the piece leading into it, but such a ditch would probably be objectionable. "W. G." might dig a dead well, or say a hole 5 ft. deep at the lowest point, lead the drain into it, and fill the well full of stones. This would be a cheap way out of the difficulty, and would probably answer the purposes.—E. H.

3654.—**Drying Manure.**—It is contrary to scientific teaching to assume that the mere act of drying, whether naturally or artificially, deteriorates manure. If, however, exposed in the open air and moistened by rain, then a considerable loss results. It is water, and neither heat or wind, that constitutes the chief agent for the dispersal of the elements of any kind of manure. We find that deposits of guano have laid on the Chincha Islands, on the south coast of America, for perhaps thousands of years exposed to all the heat and glare of a tropical sun, and yet have lost none of their manurial properties, being in fact the most highly concentrated manure that can be found.

3657.—**Rose Cuttings.**—It is now an excellent time to put in Rose cuttings, and there it really no reason why every person who has a garden should not strike a few even without the intervention of the jobbing gardener. The best wood for the purpose is that which is hard and of the early summer's producing. Lengths of 6 in. having three buds suffice, one being at the base and the others above ground. The position should be a sheltered one, as severe frost may kill some of the least matured cuttings. The soil should be good to induce strong growth when rooting, and to aid rooting early some sharp sand should be put around the base of the cuttings as fixed in the trenches cut down by the spade to receive them. In very hard weather a little hay or straw or Fern laid over the cuttings will afford valuable protection. The tenderer Tea Roses will do best if put in under a hand-light or in a frame. Once rooted, these will make plants that will long outlive the budded kinds.—A. D.

3665.—**Rabbits Gnawing Trees.**—Some of the simplest means of preventing rabbits from eating the bark of trees is to dress them with some composition that is at once obnoxious to the animals and uninjurious to the trees. In my neighbourhood the market growers get a quantity of resinous tar from the local powder mills, and use that in a very liquified state. It seems to be quite effectual. Stockholm tar, which is a vegetable product, is, we believe, quite as harmless to the trees, and as effectual. Paraffin mixed in water to the extent of half-a-pint to a gallon of water is also useful and harmless. If some cow manure and soot be stirred in with it it will prove all the more deterring. A solution of urine, soot, and clay is also very objectionable to the animals. It is desirable that whatever deterrent is employed it should be cheap, easily applied, harmless to the trees, and effective in its purpose.

3667.—**Violets in Autumn.**—It is not possible to ensure the blooming of Violets in the autumn, as it is not the natural season. If plants have been warranted to bloom in the autumn, then you have been deceived. Still, with good culture in the spring and summer, keeping the plants free of runners, and planting these up to produce a succession of robust plants, it is possible to get the crowns so strong as to make them throw a small proportion of flowers in the autumn. Under the very best culture, and with one of the best growing seasons for Violets ever known, our market growers are only finding a mere sprinkling of blooms. The real crop of flowers will not come until March.—A. D.

3568.—**Slugs and Worms.**—Dissolve 4 oz. of carbonate of ammonia in each gallon of soft water.—F. W. P.

3666.—**Begonias and Calceolarias Dropping their Buds.**—The dropping of the blossoms is probably due to extremes in the management. Regularity in attending to the wants of the plants, especially in watering, is very necessary. It is also important that the soil and drainage should be in a healthy state, so that the moisture may pass freely away.—E. H.

3647.—**Leather Shavings as Manure.**—I have always found the best way of applying curriers' waste is to dig it into the land and leave the roots to deal with it. In this way nothing is lost, and when surrounded by roots in a state of activity it is wonderful how soon (comparatively speaking) the manurial virtue (which is very considerable) is extracted from it.—E. H.

—— All shop refuse may, if cut fine enough, be dug into the soil at once, but of course all substances that have been somewhat transposed by the process of tanning are not so valuable as manure as are the trimmings of skins and other animal attributes not so prepared. The cuttings may also be put into a heap in the open, and covered over with a few inches of soil. If allowed so to remain for several months the refuse will be found partially decomposed and more suitable as manure.—A. D.

3651.—**Drying Manure.**—This is a disputed question (as your correspondent remarks), but I think there is no doubt the sooner animal droppings are absorbed by, and covered with the earth, the better. Drying in the sun cannot add to its value, on the contrary, it probably detracts from it by permitting some of the manurial gases to escape into the atmosphere.—E. H.

3652.—**Plants for Screens under Tall Trees.**—Plant Yews, Hollies, Boxes, Arbutus, Mahonias, Aucubas, and a few Rhododendrons toward the outside if the soil is good and suitable.—E. H.

3646.—**Planting Gooseberry Trees.**—Trench the ground up deeply, say 2 ft., manuring the bottom spit by mixing some manure in as the work goes on. The surface can be manured with top-dressing any time.—E. H.

3664.—**Silicate Paint.**—The best paint for your conservatory floor is G. C. Pulford's Magnetic Paint, 77, Cannon Street,

—— This can be procured at the Silicate Paint Co., Seel Street, Liverpool; it is sold in all colours. I have tried it on bricks, stone, cement, &c., and it answers well. If you give your concrete floor two coats it will last for years, standing either drip or damp, and will never come off.—J. C. KERSHAW, *Chester.*

3714.—**Spinach Between Strawberries.**—*Miss E. F.*—Spinach may be sown between rows of newly planted Strawberries 2 ft. apart without much injury to the Strawberries. Sow the round Spinach in March, and in August or September you might sow a crop of the Prickly Spinach for winter and spring use.

3715.—**Straggling Myrtles.**—*A. C.*—Cut back in March or April, and keep in a greenhouse, syringing the plants once a day. When the new shoots are 6 in. or 8 in. long they may be stopped by pinching out the centres. You will then soon get bushy plants.

3716.—**Passion-flower Bare at the Bottom.**—I planted a Passion-flower last spring which sent up two shoots 15 ft. high. For the first 5 ft. there are no lateral branches, but plenty above this. What can I do to make laterals spring lower down the stems?—J. H. G. [Cut the plant back to within 2 ft. of the soil in spring, and during the summer stop the points of the strongest shoots.]

3717.—**Plantains on Lawns**—*F. T. F.*—Your best way would be to have the Plantains pulled up by the roots now the ground is soft. If this be persevered in through the winter and spring, and any that remain are now allowed to flower during summer, you will probably exterminate them in time.

3718.—**Marie Louise d'Uccle Pear.**—Would this Pear succeed against an Oak fence about 6 ft. high, facing south, clay soil? Will the unevenness of the wood be injurious to its growth?—C. G. [If the soil is well drained, the Pear tree would do well in the position you name.]

3719.—**Hyacinth Bulbs going Mouldy.**—A short time since, finding that two Hyacinth bulbs were going mouldy, I applied flowers of sulphur. Ever since the water has smelt after standing a few days. Can you explain this? The water is changed every three weeks. —T. S. S. [Place the bulbs on a pot full of Cocoa-nut fibre or damp sand for a week or so till they emit roots, then put them back into the glasses; also put a few pieces of charcoal in the water.]

3720.—**Artichokes**—*F. E. M.*—The Globe Artichoke is an ornamental-leaved dwarf-growing plant, which bears large heads composed of fleshy scales. The heads and stalks are cooked in various ways and eaten. The Jerusalem Artichoke is a plant exactly like a Sunflower, growing 8 ft high, and producing tuberous knotted roots, which are generally boiled and mashed in the same way as Potatoes.

3721.—**Solanums.**—*Zara.*—Cut the plants back in spring, and plant them out-of-doors in good sandy soil. Lift and repot in September.

3722.—**Chrysanthemums after Flowering.**—I have some good Chrysanthemums in a conservatory; what is the best treatment for them when done flowering in order to ensure good plants for next year?—AVE. [Cut them down close to the pot, and place them in a frame or keep them in the greenhouse. When nice young shoots 3 in. or 4 in. long spring from the bottom, take them off, and put them in small pots of sandy soil; plunge in ashes in a frame, and pot on as required, moving them out-of-doors in April. Throw the old plants away or plant them out in the garden.]

3723.—**Gloire de Dijon Rose in Greenhouse.**—*Gloire de Dijon.*—If you are obliged to keep the pot in which your Rose is growing near to the hot-water pipes, it would be advisable to bind some hay bands round the pot, which keep damp to prevent the roots being dried up. Do not prune now, but get rid of the green fly by dipping the shoots into Tobacco water.

3724.—**Pear for East Wall.**—*C. A. T.*—Marie Louise, Doyenne du Comice, and Winter Nelis are all good Pears, and will succeed on a east wall. Plant now if the weather is open.

3725.—**Rose-scented and Ivy-leaved Pelargoniums.**—*Brum.*—These succeed well in an ordinary greenhouse. The best soil for them is loam and leaf-mould in equal parts with a little road or silver sand added. During summer they will grow well in the open air, and require liberal supplies of water; but in winter, unless they are in a warm temperature, the roots are best kept rather dry.

3725.—**Forcing Asparagus.**—*Heartsease.*—Put the roots in bottom-heat by all means if possible. You will not succeed very well by putting them in a greenhouse without bottom-heat.

3726.—**Dividing Forget-me-nots.**—*Heartsease.*—As your plant is of a scarce sort it would be well not to divide it till spring. If you then take off cuttings, and put them in sandy soil in a warm frame or greenhouse under a hand-glass, and take cuttings from these when struck, you will soon increase your stock.

3727.—**Primroses.**—Will double white and mauve Primroses flower earlier if potted and put in a cold frame than they would in the open air? and will they do with artificial heat?—HEARTSEASE. [They will flower earlier in the frame than out-of-doors. They will not stand much heat, but in January you may place them in a greenhouse or window with a view to advance their flowering. Look well after green fly.

3728.—**Mushrooms in Cellars.**—Will the manure for the culture of Mushrooms in cellars under dwelling-houses generate an objectionable smell to the rest of the house?—NOVICE. [If you grow the Mushrooms in tubs or deep boxes and keep the cellar clean and the doors shut, we do not think there will be any smell. We never found any objection to the smell of a Mushroom house.]

3729.—**Violet Culture.**—I have a border sloping south and west, protected east and north; old garden soil. How can I grow Violets on it?—VIGORNIS. [Give it a good dressing with rotten manure, dig it deeply, procure some good strong plants now, and plant them in rows 1 ft. apart each way. They will flower in spring. During summer give plenty of water and cover the ground between the rows with rotten manure. If convenient select some of the best runners which will be formed, and peg them to the ground and remove the remainder When those pegged down are well rooted, sever them from the parent plants and make a new plantation with them. Do away with the old plants the following summer, and repeat the operation of planting young runners. By this means you will always have young and healthy plants which will flower well.]

3730.—**Heat for Cucumbers.**—*Constant Reader.*—If you wish to grow Cucumbers in winter you must have a bottom-heat tank. Brick and cement would probably be the cheapest.

3731.—**Azaleas Losing their Leaves.**—*J. W., Barnsley.*—The plants may be dry. Soak them in a tub of water, and if air bubbles rise out of the soil let the plants soak for an hour at least.

3732.—**Lime with Potting Soil.**—How soon will potting soil be fit for use after mixing a small quantity of quicklime with it to kill insects? The soil lies in a dry shed. Would watering it be beneficial in absorbing the lime?—C. E. C. [If you have only put a small quantity of lime, you may use the soil at once. It will not hurt the plants.]

3733.—**Covering Bulbs in Window Boxes.**—I have planted my window boxes with Tulips, Jonquils, Crocuses, and Snowdrops 2 in. deep in good soil, and covered them with a layer of Cocoa-nut fibre about 1 in. thick. I should be glad to know if I must remove this covering, or will the plants grow through it, which I should much prefer? If it must be removed, how long after planting should it be done? Also may I expect them all to bloom about the same time?—BIRDSEYE. [Let the fibre remain. The time of blooming depends on the kinds planted.]

3734.—**Auriculas.**—All the GARDENING instructions direct the removal of decaying foliage from Auriculas. As fast as I remove one decayed leaf another appears, and, judging by the amount of leaf on the plants now, my entire stock will last me about three weeks at the rate of one leaf per diem. Can you instruct me in my rapidly impoverishing state? The plants are in pots under a light without heat. They are rather dry.—FLOS. [Keep the soil just moist, and give all the air possible. Remove the lights altogether in fine weather. Keep the plants near the glass.]

3735.—**Planting Peas and Beans.**—I should be glad to be informed how to prepare ground for Peas and Beans, and the depth and distance the same should be planted apart.—W. S. [Well manure and dig the ground during dry weather, level it, and for the Peas draw drills 3 in. deep and 3 in. wide, and 2 ft. to 4 ft. apart, according to the kinds sown. Early Peas should have a south border if possible. William the First, Ringleader, or First and Best require to be in rows 4 ft. apart; Blue Peter, Little Gem, and several others may be 2 ft., as they are very dwarf. Beans, if for early use, should be of the Early Mazagon kinds, and be planted in double rows, the Beans being 3 in. apart each way, and the rows 2½ ft. apart. After sowing a coat of coal ashes put along the rows ½ in. or more in thickness will help to guard the seed from mice. If the Peas are rolled in red lead before being sown, mice will not be so liable to attack them.]

3736.—**Seedling Gloxinias.**—I have a number of seedling Gloxinias, many of which appear to be dying. What part of the greenhouse, and what treatment is best to keep them through the winter?—ALPHA. [If they have good bulbs keep them on a dry shelf in a warm part of the greenhouse, but if they are only small plants recently raised from seed, you must keep them growing in a moist, warm temperature.]

3737.—**Trenching, Ridging, &c.**—*R. H. D.*—This means digging the ground two or more spits deep, and turning the soil from the top into the bottom, and bringing the bottom soil to the top. Ridging is better than rough digging. It consists in throwing the soil into a series of ridges about 3 ft. apart.

3738.—**Unfruitful Pear Tree.**—I have a Pear tree which for some years has borne no fruit, and for the last two years made no shoots more than 2 in. or 3 in. long. It is a dwarf standard, and the branches are very thickly set with old shoots a few inches long. What will bring it back to bearing?—R. H. D. [Thin out the branches, and give a good coating of rotten manure.]

3739.—**Pruning Rose Trees**—The shoots of my Rose trees are 15 in. to 20 in. long and bare at the bottom. Will cutting them off half way do any harm now? will it induce buds to break out lower down?—R. H. D. [Thin out the head, and shorten the shoots back to three or four eyes.]

3740.—**Grafting Old Pear Trees.**—I have in my garden a Pear tree about 20 ft. high; it has borne no fruit during the last three years, for which time I have occupied the house. I am told that the fruit, when it bears any, is only fit for cooking. Would you advise me to cut off the branches and graft it afresh? and if so, when and with what kind?—A. MILLARD. [We would advise you to get some good gardener to cut back the tree and graft it for you. Duchesse d'Angoulême, Glou Morceau, or Winter Nelis are good kinds, and bear well on standards.]

3741.—**Pruning a Young Vine.**—I planted a Roval Muscadine Vine in a cool greenhouse last April; when planted it had one branch. It has grown well, sending ten branches out of the sides of main branch of medium length, and strong. Am I to cut these off at the bottom close, or leave four or five eyes? Is now the time to prune it?—E. M. [Prune the side branches in to two eyes. Now is a good time if the leaves have fallen and the wood is ripe.]

3742.—**Protecting Budded Roses.**—I have a lot of Roses that were budded last July. Some have grown out a little, and some have not. The two last winters were so severe that I lost many Roses, and I am afraid I shall lose these if not protected. They are in Derbyshire.—E. M. [Put a little straw or Fern round the heads.]

3743.—**Ferns in Rooms.**—I have a small fernery in a room where fire and gas are used. Last summer I had it filled with Ferns, but the soil in the pots became mouldy and the fronds died off; they got plenty of ventilation every morning. Will the dry atmosphere of the room injure them? There was never any evaporation on the glass.—MOTHERWELL. [The gas and dry air would injure them. You should give them air by day, and shut them up after sprinkling them with a little tepid water before the gas is lit. Be careful how you water at this time of year.]

3744.—**Celery and Cauliflowers.**—I am having a small frame made in which it is my intention to grow early Cauliflower and Celery plants for own use, and the surplus for sale. As this will be my first attempt to manage a frame, I should be glad if you would put me in the right way.—THOMAS JACKSON. [Early in February fill the frame with stable manure and leaves, which well tread down. The frame must be nearly full after treading to allow of the material settling down. In the course of a week, put 1 in. of fine soil on the top, and sow Early London Cauliflower. Keep close until the plants are up, then give all the air possible. When large enough to handle, prick out the plants into a border of good soil where they can be protected during severe weather by a mat. Then sow in your frame Sandringham, Incomparable, Solid Red, or other good kinds of Celery. When the plants are up, prick them out in the frame 3 in. apart, and give all the air possible. Plant out in trenches when the weather is mild enough for that operation.]

3745.—**Fuchsias in Plant Case.**—I have a few Fuchsias (in a plant case projecting from the window) which I have dried off, but this last week they have started to bud again. May I re-pot and allow them to grow? or what must I do? I may add that I have a heating apparatus in the case.—MOTHERWELL. [You should prune them back slightly and re-pot, and if you can keep a temperature of 50°, they will go on all right.]

3746.—**Cucumbers and Tomatoes for Market.**—*Subscriber.*—A full account is given in Shaw's "London Market Gardens," 2s. 9d., post free from our office.

3747.—**Wintering Plants.**—Having some Polyanthuses, London Pride, &c., and my experience being that they do not survive the winter here if left in the open, how shall I preserve them?—J. HARRISON. [Lift them and pot them, and place them in a frame; they will come in well for window decoration in early spring, and may be again planted out after flowering.]

3748.—**Fellowship of Horticultural Society.**—How can a fellowship be obtained of the Royal Horticultural Society?—H. R. B. [Apply to the secretary, Royal Horticultural Society's Gardens, South Kensington.]

3749.—**Cutting Hollies.**—*S. P. A.*—You may cut your Hollies now, but it would be better to leave them till March or April. Cuttings should be put in in September or October.

3750.—**Neglected Strawberry Plants.**—*S. P. A.*—Give them a coat of rotten manure, and in July procure fresh runners, and make a new bed.

3751.—**Broad-leaved Myrtle.**—*Captain A.*—If you prune it well back in April or May it will break into fresh growth, and if this gets well ripened by the sun it will probably flower.

3752.—**Treatment of Lilies and other Bulbs.**—Ought Liliums of various kinds just received from a nurseryman to be potted at once to bloom in the summer in a greenhouse? if so, when potted what treatment will they require? Also Gladiolus bulbs for autumn flowering out-of-doors: ought they to be potted or planted? Also, whether Musk Hyacinths are valuable and rare? and whether they are very small bulbs? and what treatment do they require?—E. A. [Pot the Lilies at once in well-drained pots of sandy loam, rotten manure, and a little peat if convenient. Bury the bulbs about 2 in. below the soil, and place the pots in a cool greenhouse or frame. Do not water till growth commences, unless the soil gets very dry. If you do not fill the pots more than three-parts full of soil, you can earth up with good rich material when the pots are full of roots. Plant Gladioli in April or May. Keep them in a dry cool place till wanted. Musk Hyacinths may be planted now. They are very pretty either in the open ground or in pots. The bulbs are small and not expensive.]

3753.—**Potting Chrysanthemums.**—Is it too late to pot Chrysanthemums, or had I better let them remain in the ground until the spring?—F. E. [If the buds have not commenced to expand, you may lift the plants and pot them. Give a good watering, and syring overhead daily for a week. Place them in a cool, airy greenhouse. In spring take cuttings and grow young plants; they are much better than old ones.]

3754.—**Spiræas.**—About a month since I took up some Spiræas, potted them, and placed them in a cool greenhouse. The leaves are now turning yellow. Can you tell me the reason?—F. E. [Spiræa japonica is a deciduous plant and loses its leaves in autumn. Remove the leaves as they wither, and new ones will soon be produced.]

3755.—**Culture of Chrysanthemums.**—*E. M. H.*—Several long articles have been given on the subject in GARDENING from time to time, and doubtless before the time arrives for propagation we shall give further information. Now is a good time to visit the shows, &c., and select what kinds you require.

3756.—**Tulips in Window Box.**—I have some Tulips in a window box partly shaded by the window? ought I to water from time to time when the soil is dry? E. M. H. [Yes, when the soil gets very dry; but do not give too much till growth commences.]

3757.—**Treatment of Cinerarias and Primulas.**—I have some good plants of these, which were raised from seed in May last. Up to the present I have been nipping the blooms from the Primulas, and some of the main stems of the Cinerarias have been cut down to make them bushy. Shall I place the plants in a heated frame to bring them into bloom? I do not want to force them, but fear they will not come on right without heat. I keep them in cold frames and windows protected from frost, as I have not a greenhouse.—SAXON. [Do not stop the main shoots of the Cinerarias; you will spoil the plants. Such practice is very well with plants raised from cuttings but seedlings if well grown are usually bushy with stopping. Keep the plants in a frame from which frost is well excluded, and use fire-heat only when absolutely necessary. The Primulas want a little more heat and a drier atmosphere. Give air at every favourable opportunity, and keep the plants near the glass.]

Names of Plants.—*M. T. L.*—Anemones. We can only insert your communication as an advertisement. ——*J. H. C.*—Pearly Aloe. ——*Blackpool Subscriber.*—Apparently Convolvulus Soldanella, but cannot tell accurately from such material.——*Zara.*—We do not know the plant from the material sent.

Flower Stakes.—*R. B.*—See our advertisement, columns.

Harroviensis.—Saxifrage of some kind. Send again when in flower.

Cucumber Growing.—*D. T.*—Shaw's "London Market Gardens" would probably suit you. Price 2s 9d., post free from our office.

W. P., Lancashire.—We cannot name the bulb without seeing leaves or flowers.

India-rubber Plant.—*G. R. S.*—Ficus elastica is the botanical name of this plant.

Delphinium Belladonna.—*Amateur.*—Mr. Parker, of Tooting, mentions this kind in his catalogue.

Book on Table Decorations.—*W. J.*—"Floral Decorations for the Dwelling House," by Annie Hassard, post free, 5s. 4d. from our office.

QUERIES.

3758.—**Ferns for Miniature Fernery.**—Under the head of "Town Gardening" (Nov. 6), a few hints on the formation of rockeries, and more especially on the cultivation of Ferns under glass, are given. Will the writer of this article or any one else kindly inform me the names of the dwarf varieties distinct from the larger kinds which can be suitably arranged in such a place? and if it is intended to plant them out in suitable compost or grow them in pots? which way would answer the best? Also if any of the greenhouse varieties would thrive and stand the winter without any artificial heat? also the names of any Mosses that would do amongst the Ferns, so as to form a miniature Fernery under glass, say for a frame 4 ft. deep and 8 ft. wide?—C. B.

3759.—**Heating by Hot Air.**—I purpose carrying hot air from a chamber behind a kitchen fire to a conservatory in order to heat it. Perhaps some reader could tell me if it would be deleterious in any way to the plants, and would be likely to prove effectual.—H. B.

3760.—**Forget-me-nots for Pot Culture.**—Can any one tell me which is the best Forget-me-not for pot culture, and how best grown?—S. L.

3761.—**Wintering Hyacinthus candicans.**—Will any one tell me the best way of wintering the bulbs of Hyacinthus candicans? They are in an open border where they flowered well, and are 6 ft. high.—E. E. W.

3762.—**Climbers for Covering Trellis Work.**—I wish to cover a trellis facing south-east with creepers that would grow quickly and would be green most of the year to form a screen. I shall be obliged by any one naming suitable plants.—S. M.

3763.—**Moss and Fruit Trees.**—My Gooseberry trees, and also nearly all my other fruit trees, are covered over with a green Moss. Can any one give me a remedy?—J. J.

3764.—**Marechal Niel Rose.**—I have a Maréchal Niel Rose which was two years in the garden, where it grew pretty well, but never bloomed. I was told by a gardener that it would not bloom this far north in the open. I took it in last winter, and put it in a large pot; it has grown well this summer, but no sign of bloom; now it has done growing, as the leaves are falling off. It has three long shoots, one being 13 ft. long. Should I stop these shoots or not? They are very small and wiry for about 2 ft.—D. W.

3765.—**Brandy Mint.**—Is there such a plant or herb as Brandy Mint? If so, can any one inform me where I can get the seed of the same?—H. DYER.

3766.—**Preventing Tree Stumps from Growing.**—Will any reader kindly say by what means cut down trees may be kept from shooting again? I have tried painting them with gas tar, but without effect.—SUBSCRIBER.

3767.—**Unfruitful Walnut and Mulberry Trees.**—I have in my garden a Walnut and a Mulberry tree, the former being about fourteen years, and the latter about sixteen years old, neither of which ever produced fruit. The trees leaf well, and appear quite healthy. I need hardly say the climate of Queenstown is very mild, and one would imagine such trees should do well here. Perhaps some reader could kindly give me a hint as to treatment.—W. C. S.

3768.—**Uses of Logwood.**—Having a quantity of logwood and fastic which has been used for dyeing purposes, I should be glad to know if I could turn it to any use in the garden.—J. T. M.

3769.—**Cockscombs in Dwelling-houses.**—Could Cockscombs and the Sensitive Plant be raised from seed in a dwelling-house? if so, will some reader kindly give me instruction how to proceed?—W. S.

3770.—**Anemones.**—I wish to plant some Anemones. Last year my bulbs were quite a failure. Will any reader give me directions as to time of planting, treatment, &c.? Mine is a garden now considerably surrounded by houses, though with very open ground just beyond; south of London, tolerably sunny; soil fairly rich, well drained loam, not very stiff.—ANEMONE.

3771.—**Rustic Work.**—Will some reader kindly inform me what glue and cement is used in making rustic vases, &c., that will resist damp, and the probable cost per lb. of same? Also would a coating of pitch or coal tar inside vases injure the roots of plants? I have seen vases in virgin cork finished off with a kind of plaster, coloured, and varnished. What plaster and varnish is used? and are the colours mixed up with oil or water?—W. S.

3772.—**Roses in Pots.**—I have Gloire de Dijon, Maréchal Niel, Dr. Andry, John Hopper, Fisher Holmes Roses on their own roots, or budded very low. They are as bushes now out-of-doors, where they have been since midsummer. What is the next thing to be done to them? I thought of bringing Maréchal Niel into a little heat to start it on; is that right? If so, what is to be done to it first as to pruning, repotting, top-dressing, &c.?—A. B. T.

3773.—**Cropping a Garden.**—Having taken a piece of Grass land, 50 yards by 18 yards, which I am now digging up for garden purposes, about one-fourth for flowers, the other for vegetables, I should be glad if any reader would give me a list of the best kind of flowers to cut for bouquets for next spring and summer. Also, I should be glad of a little instruction with regard to the vegetable portion, as I am a new beginner; as my income is small, I thought I might increase it by means of the garden, having about three or four days per week at my disposal.—HOPEFUL.

3774.—**Passiflora cœrulea.**—I have one of these in a 6-in. pot, trained in a sitting-room window. It is now about 6 ft. high—only one long stem. How has it to be treated? Must it remain in its present pot? and should it be cut down or not?—J. C., *Whitley.*

3775.—**Lilium Washingtonianum.**—I have a bulb of this Lily which I purchased last month. I have planted it in a 6-in. pot, using a soil composed of good fibry loam, with some sand, peat, and leaf-mould added. The pot has been placed in a cold frame. Messrs. Barr & Sugden's catalogue says: "Washingtonianum comes from a very high elevation, where the summer is short and hot and the winter severe." From this I would infer that the pot containing the bulb would be best out-of-doors in the snow and frost. Will some reader kindly advise me as to its treatment?—SAXON.

HOW TO CONSTRUCT A SELF-ACTING FOUNTAIN FOR THE AQUARIUM.

A FOUNTAIN is indeed a very pretty and pleasing feature in connection with the aquarium, or in a window garden, Fern case, or rockery, always being agreeable to the eye, and suggestive of coolness in hot weather. There are many and varied ways of constructing it, but if the work be entrusted to one whose trade is partly in connection with such operations the cost becomes far more than is the case when a fountain is made by one's self with simple materials. A fountain constructed in the following manner has worked so successfully, and with so trifling a trouble, that many readers of GARDENING may like to know how it was done. I must not forget to mention, however, that it is fitted up in close proximity to the tank which is supplied with water for household purposes, so that a good supply is always at hand and easy of access, and unless anyone who may be inclined to construct one after my directions have this advantage more difficulty will be found in making it purely self-acting. I procured an arrowroot tin (a large biscuit tin answers quite as well) and a penny tin funnel; in the bottom of the arrowroot tin I cut a round hole, a ¼ in. smaller than the wide end of the funnel, and soldered this latter article over the hole, making it perfectly water-tight. The small end of the funnel just takes ¼ in. lead pipe, one end of which is inserted and soldered in it, and carried to the middle of the fish tank described on page 241, No. 70, of GARDENING, the other end running up the centre of a conical-shaped piece of work composed of Virgin cork, which is fastened by good Portland cement to an oblong square stone, 2 in. in thickness, and which is covered with pieces of coke, shells, cinders, and broken brick, all cemented together as rustically as possible, and which prevents the cork from rising. The end of the pipe running up the centre is on a level with the edge of the conical rockwork, the top of which is 2½ in. from the water's surface. A tight-fitting cap is placed on this end of the pipe. with one, two, or more (as may be desired) finely-drilled holes, thus forming the jets. The entire length of the supply pipe and the height of the tank depends, of course, upon the altitude it is desired the jet should reach, as, with a very fine single one, water will almost if not quite find its own level when the tank is full, the weight of water being considerable. But if a small brass tap is soldered in the pipe at some convenient place the height to which the water may be thrown can be regulated at will.

Whatever the fountain is fitted to there must be a waste pipe. As I mentioned before, the tank made in the manner described is fitted up close to that which is filled every day from the waterworks, therefore no difficulty is experienced in keeping my own filled continually, which is done with a syphon, the large pipe of which is ¾ in., and the small one ¼ in. One end of the pipe is let down into the tank to within 3 in. of the bottom, a small piece of perforated zinc being attached to prevent anything going up the pipe and stopping the flow of water, and the other end is pinched up to the same size as the fountain jet; it is bent over the wall and conducted to my own supply tank 1 in. below the top, and turned in slightly, so that when the air is drawn out and the water enters this syphon it can scarcely be heard running, neither does it come in at any greater speed than it passes out at the jet. The smaller pipe of the syphon is sufficiently long to enable me to reach its end with ease, and by first filling the small tank and then drawing the water through the syphon the supply is continual. A small water-tight cap fits on the end of the small syphon pipe. By blowing vigorously into the syphon the water ceases to run in directly it is heard to bubble.

Thus it will be seen that this fountain can be entirely self-acting as long as the water in the larger cistern reaches the syphon and is once set at work. But it must be remembered that the smaller reservoir must be lower in position than the larger, otherwise it will be impossible to get the water to run in satisfactorily. My own fountain fitted up in this way will play day and night for a whole week, or as long as desired, and does not cause the slightest trouble in any way, and the expense has only been a few shillings. But for those who are not provided with a supply of water close at hand it may be more difficult to erect one which will work with as little inconvenience. I have made these instructions as plain as possible in the hope that amateurs may try the experiment, as, being in no way complicated, the materials are easily obtained, and the working simple enough. To anyone not able to fully understand these matters I shall be pleased to give further information.

NEWT.

BEES.

Feeding Bees.—The old axiom that there is wisdom in a multiplicity of counsellors does not seem to apply to advice relating to bees. What must "A Weaver" think when he finds "Bar Frame" advising him to feed bees now, and "Apiary" that he should not feed until March next. This really is absurd advice, for the poor bees if short of food may all die in the meantime. It is wisest to feed now; during the present open weather the bees are all active, and not only want food, but if not fed will be consuming what honey they may have stored, for the past season has not been a good one for honey gathering, although much better than last year was. But "Bar Frame's" advice to feed so that only one bee at a time can be fed is really too ridiculous. If in a strong stack there are 10,000 insects, what chance have all the rest when only one bee at a time can get food. In feeding now and for the past few weeks with pure loaf-sugar syrup, I use broad-mouth pickle bottles, and tie over these pieces of clean fine muslin, twice or thrice folded. Through this the syrup percolates steadily and certainly, and quite 25 to 30 bees can feed at once. The bottles need re-filling every third or fourth day. With plenty of food in the hive the insects are not only safe from hunger, but are also more fully protected from cold, as the full comb admits the presence of less air than an empty comb does, besides presenting greater obstruction to the action of external cold. It is not well to promote artificial heat, but it is good to afford the hives shelter from cold and rain. This done, and with a good store of food, there is little doubt but that next spring the insects will give a good account of themselves, and repay in strong swarms the aid given them now.—A. D.

POULTRY.

Fowl Keeping in Small Spaces.—I have read with much interest "T. F.'s" communication on this subject in GARDENING, October 30, and as I keep both sorts, dark Brahmas and Cochins, can fully endorse his remarks on their dirty habits and perpetual tendency to set. I have also had some experience with Hamburghs, though not at my present residence, and judged they were the least able of any to bear confinement, requiring a grass run and plenty of it, and the most liable to that curse of the poultry yard—roup. I intend getting rid of my present stock, and thought of giving the Dorking a trial, but should much prefer the non-setting kind, as that would better meet my requirements. Can "T. F." give me any further information on the subject? The space at my command is an irregular piece fenced off at the bottom of my garden, 40 ft. long, 22 ft. at the wider end, diminishing to 10 ft. at the narrower and lower end; there is a fall of about 18 in. in the whole length, and the house and sheltered run occupy the upper side, the other three being enclosed by a fence about 5 ft. high. The whole surface has been dug up and asphalted, so that all rain and water runs off quickly. I have a pit sunk on one side in which is put dead leaves, grass cuttings, and other garden refuse; and also a dust and broken brick and mortar heap. Would the black Hamburghs thrive in such a place? and would they not readily fly over the fence, even with one wing cut? are they hardier than the gold and silver-pencilled varieties? and where is the best place to obtain them?—J. B. M.

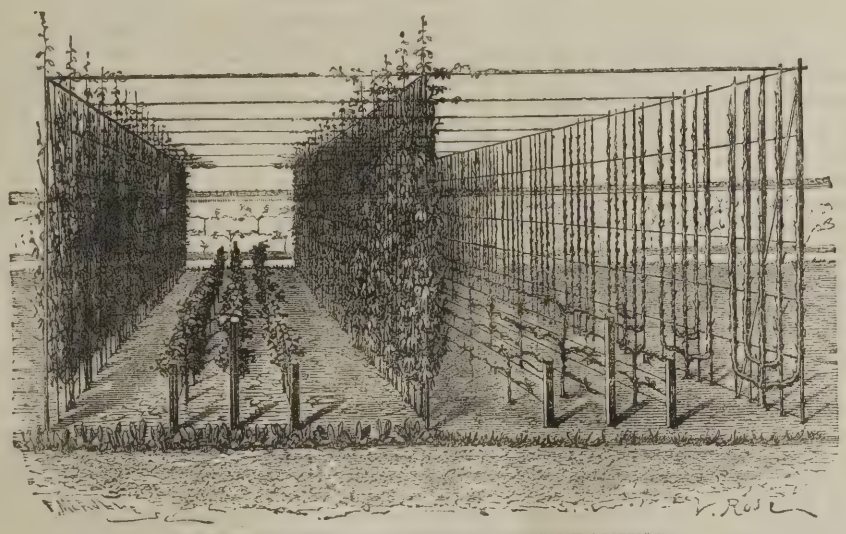
Moorhen (Gallinula chloropus) in Gardens.—Will any of your readers inform me how I can catch these birds? and what food I am to give them to draw them to my traps? or whatever other means may be devised for their capture? Should you not like to answer this in your journal, as I know the birds are favourites with many people, perhaps some of your correspondents will answer me by private letter.—C. THURNALL, *Whittlesford, near Cambridge.*

GARDENING ILLUSTRATED.

VOL. II.—No. 91. *SATURDAY, DECEMBER* 4 1880. PRICE ONE PENNY.
REGISTERED FOR TRANSMISSION ABROAD.

IMPROVED FRUIT TREE TRAINING.

FRUIT culture being now so important a matter, any way of planting which combines economy with efficiency will, doubtless, be readily adopted by fruit growers. Our illustration represents a method of planting and training fruit trees which anyone possessing a fair-sized garden might copy with advantage. The trees are, as will be seen, trained to a light trellis, the supports of which are of T iron, placed at intervals of about 20 ft. Along these supports are fastened horizontal wires, 2 ft. apart, the trellis being about 10 ft. high. These trellises are placed about 12 ft. apart, or, if the trees are trained higher than 10 ft., more width must be allowed. A good guide in this respect will be to always plant a little wider apart than the height of the trellis, so that one row of trees will not shade the other. Strong wires are strained across the tops of the trellises to hold them together. The trees are planted 3 ft. or 4 ft. apart, and each tree has 5 branches trained upwards by means of willows or deal sticks, which are removed when the branches have reached the top of the trellis, ample support being then afforded by the horizontal wires. Our illustration on page 473 shows the details of the plan on which the trellis is constructed. In order to economise space, Dwarf Cordon Apples on the Paradise Stock are planted between the rows of Espaliers, and between the Cordons might be planted early Strawberries, or similar crops. The advantages of this plan of training are—first, the trellises are cheaply made and durable, giving no further trouble after being once erected; second, the trees, by being trained in an upright direction, will cover the trellis in three years if good trees be secured and well planted at starting; third, a large quantity of the best market Pears may be grown in a small space, and the Cordon Apples will also yield heavy crops of fine fruit. In regard to soil and planting, we have so recently given long articles on the subject that it is unnecessary to refer to it here, and last week we gave an engraving of Pear trees for high walls, with notes on their culture. The remarks there made are equally applicable to the requirements of the form of tree now under notice. It may, however, be well to give a short list of the best market Pears, as these, as a rule, are the most useful kinds to grow, even for home consumption. Among early market Pears ripe in July and August may be mentioned, Beurré de l'Assomption, a large-sized, lemon-yellow kind; Williams' Bon Chrétien, and Madame Treyve. These are succeeded by Citrôn des Carmes, a medium-sized fruit and an abundant bearer; Belle et Bonne, Beurré d'Amanlis, Beurré Superfin, Fondante d'Automne, Gratioli of Jersey, Hazel, Louise Bonne of Jersey, Marie Louise d'Uccle, Autumn Nelis, and Seckle. These keep up a supply till the end of October, after which come into use until Christmas, Vicar of Winkfield, Winter Nelis, Napoleon, Marie Louise, Duchesse d'Angoulême, Doyenné du Comice, Althorp Crassane, Colmar d'Aremberg, Bishop's Thumb, Beurré Léon le Clerc, Beurré Hardy, Beurré de Capiaumont, Beurré Clairgeau, Beurré Bosc, and Beurré Bachelier. Amongst kinds which come into use after the new year has set in may be named Bergamotte de Esperen, Glout Morceau, Knight's Monarch, and Easter Beurré. Many other kinds are also grown for market, but these form the chief supply. The Pitmaston is a new Pear of large size which has lately been grown for market. In flavour it resembles Marie Louise, but as a market Pear it is inferior to that kind. It comes into use during October and November.



IMPROVED ESPALIER FRUIT TREE TRAINING.
Trellis 10ft. high, with supports of T iron and horizontal lines of galvanised wire.
Cordon Apple Trees on Paradise Stock between Espaliers.

Large Pears.—Several persons have sent you accounts of their Pears; let me give you mine. I gathered a short time back 18 Catillac Pears, the united weights of which amounted to 18½ lbs. Of these, the heaviest weighed, respectively, 1 lb. 9½ oz., 1 lb. 4¼ oz., 1 lb. 3½ oz., 1 lb. 2½ oz., and 1 lb. 2 oz. There is no better baking Pear than the Catillac. —H. G. M., *Michelmersh Rectory.*

How to Keep Apples during the Winter.—Mr. Sidney Ford, of The Gardens, Leonardslee, Horsham, is in the habit of sending to the meetings of the Royal Horticultural Society at South Kensington during the months of March and April, collections of Apples, both dessert and culinary, so well kept as to lead one to wonder how it is the fruit look as fresh and plump in spring as in October and November. Mr. Ford's method is both simple and efficacious. He may be said to commence by thoroughly cleansing his fruit room each year shortly before the Apples have to be placed in it, giving the walls a good coating of whitewash, and thoroughly cleaning the shelves. Then he is very careful that each sort is quite ready for picking when the gathering takes place. The fruit is stored when it is quite dry, and handled with the greatest care. On the shelves the fruit is placed in two layers, and no straw is used. Plenty of air is kept in by night as well as by day, and the ventilators are closed only when hard frost threatens. Mr. Ford is a great believer in keeping his fruit room thoroughly airy, and as cool as possible; and we are bound to state we have known warm, close fruit rooms, in which the fruit kept very indifferently indeed. Indeed, Mr. Ford's plan may be said to be free from any "coddling" processes; at the same time, handling the fruit is resorted to only when absolutely necessary. Gentle handling is a matter of much more importance in keeping fruit than many imagine. Pears are managed in the same way as Apples, and they also keep wonderfully well. Though the Apple crop proved this year better generally than it has for a few years past, many good standard sorts are scarce, and commanding good prices. When fruit is scarce every precaution should be taken to preserve it as long as possible, and in the belief that the foregoing rules may be of service just now, they are set down.—R. D.

Pruning Fruit Bushes.—The plan of cutting the young wood of Gooseberries and Currants close in to the main shoots, and leaving nothing but a few young spurs, is the mode of pruning most commonly practised, but it is questionable whether or not this is the best way of pruning to secure fine crops. I have tried bushes side by side pruned in this way, and otners in which was left a good quantity of young wood, and the latter invariably bore the best crops, both as regards quantity and quality. Cutting most of the young wood off limits the fruit-bearing proportions of a tree very much, and I could name a good many instances

in which aged bushes were killed altogether by annually persisting in cutting away all the young wood. The worst and common way of pruning bush fruits is to cut in all the side shoots to one eye or two from the old wood, and finish off by cutting the leading or top shoot some 2 in. long. The best and most fruit is produced by the few young buds that are left, and anyone may understand that to leave more young buds would be a certain means of ensuring more fruit. Besides, to keep up the strength of a bush or tree, it is necessary that young wood should be allowed to develop itself in some way or other, but, as a rule, this is not taken into consideration. I have said that close cutting in is the worst way of pruning. Now, I consider the best way to be never to leave the wood too close together; leave the young shoots at least 4 in. long, and the top or leading shoot 10 in. or 12 in. long. Cut out some of the old branches every year, and allow one or two of the strongest of the young ones to take their places. Let those interested in the matter try this plan, and observe the result. The finest crops of Gooseberries and Currants which I have ever seen were growing in a garden not far from where I now am. The bushes had been allowed to grow so freely that they were in the form of small trees; the branches were not crowded, and the fine, large fruit was hanging in closely-packed rows and clusters, some 6 ft. in length. I am strongly of opinion that where the close cutting in of Apple and Pear trees is practised, as it is in many places, it is as injurious to the trees in the way of producing canker and other diseases and short crops as it is in the case of Gooseberries and Currants.—Amateur.

PLUMS AND APRICOTS.

In districts where the Apricot generally fails on the open wall it may often be seen flourishing against the gable end of a warmly-situated cottage or farm-house. The chief drawbacks to the successful cultivation of Apricots are unsuitable soil and an unfavourable climate—the latter usually exercising more influence than the former. But soil that is unsuitable may in a limited space be modified and altered in character at a trifling expense, while climate may, to a certain extent, be ameliorated by shelter and selection of the most favourable sites for planting. The walls of any dwelling or stable are more warmly situated, and consequently enjoy a better climate than most garden walls, especially where the latter are of a considerable length, with no arrangement, either temporary or otherwise, to counteract the effects of the keen cold currents that rush along their sides.

Planting.—In planting Apricots or other fruit trees against either cottages or farm buildings the soil should first be thoroughly broken up at least 6 ft. in width from the wall, and 2 ft. deep. If of fairly good quality, that is, neither clay nor sand, nor one in which either predominate to an injurious extent, and if the subsoil be dry, which in most cases it would be close to a dwelling-house, the trees may be safely planted without any addition whatever; and the fact of the soil having been previously unoccupied by fruit trees will make their early growth rapid and vigorous. On very retentive soils, in order to ensure the health and fruitfulness of the tree, it will be better to be content with a shallower border, and that might be raised 6 in. or so above the ordinary ground-level. Concrete 4 in. in depth should be placed over the bottom of the hole, resting on the firm, unmoved subsoil, to keep the roots from penetrating it, and to compel them to take a horizontal direction. Some efforts should be made to renew a portion of the soil where it is bad, and there is scarcely a place where a few barrowfuls of fresh turfy soil may not be had if looked sharply after. Whilst speaking of shallow borders, I may say whoever adopts them should see that the trees do not suffer from drought in a dry season. The necessity for this has often been overlooked, and the trees have become stunted and starved without the cause being suspected. No doubt deep rooting, even on good soils, is a disadvantage in some respects, for the nearer the roots are to the surface the more manageable is the tree.

Mulching and Watering must not, however, be neglected, more especially when the trees are heavily cropped. It need hardly be stated that as water enters largely into the composition of all fruits, unless it is freely given in hot summers, the fruit must be small. It is the same with cultivated fruits as with domesticated animals; when in a wild state they can cater for themselves, but under more artificial conditions and circumstances their wants must be provided for.

Training.—The best form of training for all stone fruits is what is commonly termed the fan shape, and although we may take it as a general principle that the less the knife be applied to Apricots the better, still the tree must be headed back in its early stages to insure the necessary breaks for clothing the bottom; if this be not done the bottom of the wall will always remain indifferently furnished. Experience has proved that a good deal may be accomplished in training by keeping the middle of the tree always open, thus diverting the sap as much as possible to the lower limbs.

Top-dressing.—Often where Apricot and other stone fruit trees have been indifferently progressing, a dressing of lime and soot over the borders and lightly forked in has been found of great service to them. Lime rubble from old buildings might with advantage be mixed with the soil in planting young trees of Apricots, Peaches, and Plums, as these fruits do best in a calcareous soil, and soot is a stimulant especially invigorating and suitable without encouraging grossness of habit. It is also a very good remedy for nearly all insect pests, and may either be mixed with soft water, and syringed over the trees, or the trees may be dusted with it in dull, showery weather. Of course this mode of application is not suitable after the fruit has reached a good size. But if insects be well kept down in spring, as they ought to be, there will be no necessity for using it afterwards.

Pruning.—There are two main principles adopted by different cultivators in pruning and training the Apricot, Peach, and Plum with a view to fruitfulness: One is to rely chiefly or wholly upon young wood laid in annually, and to disbud or remove all foreright shoots when only 1 in. or 2 in. long; and the other, whilst not ignoring the expediency and the necessity for laying in young wood wherever there is room, consists in taking the chief crop from spurs growing on the front of the branches which have been encouraged to develop themselves by the system of pinching and pruning adopted. The latter is the plan most generally practised, and will, I think, be found most suitable for those who have not had the advantage of a special training in fruit culture. Whether it be on artificial or natural spurs, we have all one object in view, viz., to secure a crop of fruit, and that system that gives us the best chance of success with the least trouble must be undoubtedly the right one to adopt. But in either case the necessity for disbudding exists, and ought to be carefully attended to. Where the crop is taken indiscriminately from spurs, both on the young and old branches, the disbudding in spring should be limited to thinning out the young shoots that push in profusion all over the tree. This should be done when the shoots are an inch or so long, when they can easily be rubbed off with the thumb and finger without running any risk of leaving any permanent wound in the bark of the branch; pinching or summer pruning will afterwards be an important item in successful management.

Plums.—There is scarcely any fruit so accommodating as to soil or situation as the Plum, and not only has it these advantages, but if the fruit be thinned out when the trees are overloaded, and only known good and prolific kinds planted, it is a profitable crop to grow. The Plum tree is not so long-lived as the Apple or Pear, but it comes sooner into bearing. The wind is often destructive to old standard trees, for as age creeps on them the branches become more brittle. When this is the case if the main trunk be healthy, I have often seen new life and vigour infused into old trees by heading them down, as they break readily out of the old wood. If this heading-down process be extended over two or three years, the trees will scarcely feel the check, and the gradual thinning will prevent the total loss of the crop, as the young wood on an old tree commences bearing immediately. But dwarf trees are the best to plant in small gardens; they bear well when trained in the bush or pyramidal form, and small or moderate-sized trees are easily protected when large trees must take their chance. So far as profit is concerned, I believe a plantation of Victoria Plums will yield a larger return for the outlay than any other crop, but for home consumption it will be advisable to add a few other kinds in order to extend the season of bearing. As wall trees, Plums will grow and bear well on any aspect, and it often happens that trees on a north aspect will bear abundantly when those on other aspects fail; this is due in some measure to late blooming, and also to the gradual rise of temperature on a north aspect after a cold, frosty night in spring. The sun does as much harm as frost if its rays fall on a frost-smitten tree early in the morning, and it is in the shade imparted by a thin flimsy covering warding off the sun's rays in the early morning that a crop has been saved as much as by the protection afforded from frost. The pruning, training, and summer management of the Plum so much resemble those already given for the Apricot, that I need not refer to them again. H. B.

VEGETABLES.

Magnum Bonum and Champion Potatoes.—Much having been said about the relative merits of these kinds of potatoes, may I be allowed to state my experience? I have grown them on both light and heavy soils. Champions produced about 16 lb. for every 1 lb. of seed planted, and 15 per cent. of these were diseased, besides many ugly, hollow, and unfit for use. Magnum Bonum produced 28 lb. for every 1 lb. of seed, and planted on the same ground as Champions—viz., very light and good soil, and not one ugly or diseased tuber in the whole lot. This was remarkable, for from 60 lb. of seed I lifted 1680 lb. of the best-formed and best-cooking potatoes I ever saw, and this from 260 square yards of ground. The same result has followed from stiff soil, so that I consider Magnum Bonum is better formed, a heavier cropper, and better cooking potato than Champions and ripens quite a month earlier, which is another point in its favour.—G. Jones.

Tomatoes Out-doors. — Seeing in Gardening Illustrated of Nov. 13, 1880, the account of out-door Tomatoes having the disease, I thought it would be of interest to the readers to know that last year I planted out about a dozen plants of Tomatoes on a warm border, when just before the fruit ripened they all went off with the disease. I thought I would plant again this year, so I planted just in the same place, and a nicer sample of Tomatoes one would not wish to see. Not one single Tomato took the disease. I also planted some out in the open garden, which I trained to some lattice-work, which fruited better than those on the wall. From the first week in August up to the second week in November I had a good supply of fruit. The sort I have grown are Hathaway's Excelsior Large Red and Large Yellow. I find the two latter kinds are the best for out-doors. —T. H., *Tonbridge*.

Forcing Rhubarb and Seakale.—At this season of the year, when the forcing of such vegetables as these is occupying attention, it cannot be too strongly urged that many are deterred from attempting so simple an operation by the supposed difficulties of the undertaking, whereas both may be successfully forced in positions that cannot be otherwise utilised. Wherever boilers are fixed for heating hothouses, or buildings of any kind, there is, as a rule some of the main pipes that must of necessity pass through positions where their heat is not required; all that is necessary is to make up a rough box of the desired size, and plunge the roots in light soil, covering the crowns with dry leaves, fern, &c., and laying over the whole a lid to exclude light; keep the soil moist, and regulate the heat by raising or lowering the box, and as good a supply of Seakale and Rhubarb may be obtained by such simple means as from the most elaborately-finished structure built specially for the purpose.—G.

Hotbed for Seakale.—A slight hotbed, should now be made up for growing Seakale where this is wanted by the end of the year. If it is made of leaves alone, all the better, as

these are not liable to get too hot, in the way that stable manure frequently does. Make it about 2 ft. 6 in. in thickness; it may be soiled at once, and the crowns put in 6 in. apart. Any ordinary garden soil, or old potting material, will do, keeping it fairly moist, but not too wet. A small garden frame will answer to place on the top, covering it with boards or shutters, so as to keep the inside quite dark, which is better than using the glazed lights, as it would be necessary to put over them mats or litter, which in a wet state naturally cause decay.

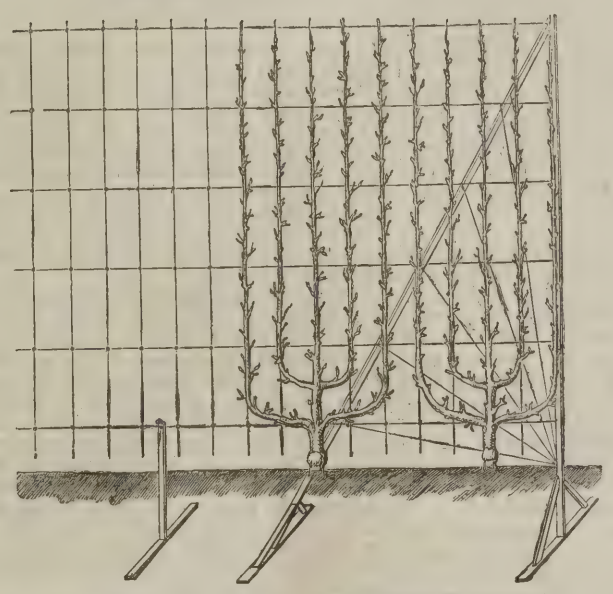
Storing Roots.—For many years the plan of keeping Carrots here was taking them to a cellar or outhouse and building them up; with every layer of Carrots was put a layer of sand, which kept them fairly well until about Christmas; but after that date they were always far from being satisfactory. My practice now is never to put more than two ordinary barrow-loads together, building them outside, head outwards, and covering them with straw and soil. We are now using Carrots taken up in October just as fresh and good as when taken up, and they will keep so until the end of May. These Carrots are used before the growing ones, which we always sow in July, and pull from the beds all the winter. The latter are much sought after, being mild, tender, and delicious. In order to keep Onions sound and free from growing, we tie them up in small hand bunches, and hang them in a draughty passage, where they are always cold. In this way we find them to keep perfectly sound and good. Parsnips we leave in the land until they begin to grow, when we lift and store them as we do Carrots for late spring use. Beetroots should be lifted before the frost touches them, and stored precisely in the same way. An advantage belonging to this plan is, that it takes up no shed-room, which at all times is useful, particularly in winter, for storing Lettuces, Broccoli, and many other things.—R. G.

Grafting Potatoes.—I was glad to see in Gardening the answer of "A. D." on "Grafting Potatoes," with which I quite agree so far as that no tangible results follow as to its effect on the tubers. If you graft on the stem of a Potato successfully I believe that you may alter the character of the plum or fruit, and that the seeds raised from the plum may be acted upon by the grafting, and in perhaps a decided manner if you can prevent the flowers from being impregnated by bees and insects, but I cannot see how it can affect the tubers on the stocks or plant grafted upon. If you graft a choice Apple on the wild Crab or the Quince it no doubt may, and does, affect the productiveness, quality, and flower of the fruit, but it does not affect the roots of the stock; destroy the scion and allow the stock to grow, and it will only produce wild Crabs. It was also stated by one of the witnesses before the committee that a variety of Potato may be improved by the selection of tubers. I much doubt whether this is the fact, except so far as this, that you may expect healthier tubers to be produced from sound sets than from unsound sets, but it will not affect the form or character of the Potato.—Querist.

A Cottager's Experience of Potatoes.—In Gardening Illustrated "Burns" gives his experience in Potato growing in the north this season. I will give mine in the midlands. I have grown this year Early Hammersmith, Ashleaf, Early and Late Rose, Schoolmaster, International and Woodstock Kidney, Magnum Bonum, and Champion. The first five sorts were bad, International and Woodstock Kidneys very bad; Magnum and Champion good, and they both cook well indeed. Of International and Woodstock I planted one peck of each, and I have a little more than my seed again. The International were a fine crop if they had been good, but I picked a sample to exhibit, and took first prize with them at our district show.—T. S.

Forming a Lawn.—In the formation of a croquet ground or a lawn it is necessary that the ground should be removed to a uniform depth, and if it is not it is indispensable that the soil in every hole should be properly rammed until it is brought to the proper surface level. In this manner the turf may have a smooth and proper foundation, and without that it is a waste of time to lay the turf at all. Soils differ much in the amount of compression which they require. Land free from vegetable matter will, after a good soaking rain, go together so closely as to need but little further compression, but fresh soil full of fibre will rot and settle for years if it is not thoroughly consolidated at the commencement of the work. Loamy soils can easily be properly handled when they are dry. If you attempt to ram them when they are wet you will form a plastic mass through which the rain will pass with difficulty, and hence the surface will always be damp and mossy, but if you ram such a soil when it is in a comparatively dry state, you may make it solid, and yet the interstices between the particles of soil will be sufficient to allow the surface water to escape with facility. In relation to new groundwork a gentleman remarked the other day: "If that work had been done by the day I should have considered I was being most shamefully robbed, but now I see that the care you insist upon is necessary, and that the work is being executed in the best possible manner."—J. S.

Indian Corn.—I think we might add to our garden productions the small variety of Indian corn (or maize). I sowed two small rows about the 20th of April last in a warm situation in the garden, and this autumn, when fully



Improved Espalier Training—showing Details of Trellis-work
(See Front Page).

grown, and before the corn became hard, I gathered some nice ears, which, when stripped of their envelope of leaves, I told the cook to nicely toast at the fire, spread a little butter on them, and send to table. They met with such a favourable reception that a further supply was requested. That Indian Corn was esteemed in ancient times we find by its being chosen as one of the first fruits the children of Israel were to offer, as we also learn their mode of preparation was with oil and frankincense. We substitute butter for the oil and dispense with the latter.—W. T. Smart.

Precautions against Slugs, Snails, and Worms.—When putting out young plants in showery weather, some sifted ashes scattered over the surface of the beds will make travelling most uncomfortable for any soft-skinned animal. Lime and soot are also distasteful to them, but the first shower not only neutralises their effect, but they have a tendency to clog up the pores, so to speak, of the surface soil; sifted ashes, on the contrary, keep the surface loose and friable, and attract and absorb what little warmth there is in the sun's rays at this season. A very light sprinkling is sufficient, and the effect is permanent. Some object to the use of ashes, but for heavy soils their application in the way just described is very beneficial, and, what is more, they can be obtained in most places for almost nothing.—H.

Manures and their Application.—The management of the manure-heap has a most important bearing upon profitable culture. All perishable substances have a certain manurial value, some for their mechanical effects, others for their stimulating properties. For heavy land, ashes, lime, soot, and sand are exceedingly valuable; in like manner clay and marl may be profitably applied in considerable quantities to light land. It is best applied in the winter after the land has been trenched, left exposed all the winter to pulverise, and lightly forked in in spring before the land is cropped. A good dressing of clay is supposed to be beneficial for about ten years. The persevering, thoughtful cultivator will store up every bit of waste matter for his manure-heap, and it is altogether impossible to make a mistake in this respect, as everything that will readily decay may be added to the heap, and in proportion as the manures accumulate and are given to the land so will the crops improve. The manure-heap should be formed in a hollow or pit near the pig-sty, where everything that comes off the land or that can be gathered from the ditches or roads in the neighbourhood should be conveyed. When fermentation takes place, if any bad smell arise scatter dry earth over it; this will arrest and absorb any effluvia or gas that may escape from the heap, as well as add to its bulk and value. I am assuming that every cottager who can do so will keep a pig, for the double purpose of eating up all waste vegetables and making manure. Liquid manure is especially useful for any crop that requires a concentrated stimulant, as it can be given just at the time it is required, and in the winter, if of no other use, it can be applied to stunted old fruit trees, taking the spread of their roots as a guide. Some years ago I treated some old Apple trees in this way several times during the winter, and the effect, as demonstrated by the produce, was marvellous. Asparagus beds, old Raspberry plantations, or old Gooseberry bushes would be much benefited by an application of liquid manure at any time when it is not required for other crops. In small gardens the pig-sty can easily be screened by planting a row or two of pyramidal Pears or other fruit trees around it. The old idea of resting or fallowing land is now well-nigh exploded, experience having taught us that by the application of suitable manures—that is, by returning to the land as far as possible the same substances that have been taken from it—the earth is practically inexhaustible; hence, there is a manifest advantage in collecting the manure from as many sources as possible for the successful development of all kinds of vegetables, and special attention should be paid to the gathering in of what is usually called rubbish. All substances that do not readily decay, such as hedge clippings, prunings, &c., should be placed by themselves, and be occasionally charred as the heap accumulates. This can be done by setting fire to it on some dry day; when well alight place over it any other rubbish, such as weeds, &c., not too heavily at first, and gradually enclose the heap all round, so that the heat of the fire is confined within it. As the fire dies out the whole will crumble down into a black charred mass, which, when passed through a sieve to take out stones or rough pieces, will make a valuable compost for Onions, Turnips, or Potatoes, or for covering any small seeds in cold, heavy soils.

If stored away in a dry place it will be found very useful in the winter for dusting over young plants of the Brassica family, Lettuces, &c. Salt is a valuable fertiliser, especially for dry, porous soils, and deserves to be more extensively used. Artificial manures are not much used in small gardens, but where

there is a scarcity of other manures, and even where other fertilisers are plentiful, a slight sprinkling of guano or superphosphate will often push a young crop through a critical period with safety. On some soils phosphates are more beneficial than ammoniacal manures. This will be found more especially the case when applied to old gardens, in which the soil has become rich from frequent manurings, but deficient in lime.

Tritonia aurea as a Border Plant.—I have had this bulb in the open ground for the last three or four years, and have never noticed the shoots to suffer in the least from frost. The clumps grow stronger each year and flower more profusely, and they get no attention beyond what I give to the border in general. They are planted in a corner facing south and east, where they get the full benefit of all sunshine until between 2 and 3 p.m. I think they kept in flower this year for quite a couple of months. I have not found them to stray very much. They are planted at the foot of a sweet-scented Clematis.—F. J., *Middlesex.*

The Golden Chickweed in Winter.—In addition to this Chickweed (Stellaria graminea aurea) being one of the most useful yellow carpet plants in summer which we possess, it may also be made to form a dense thick mass of bright golden leaves in autumn and winter. I once noticed a large patch of it in a London nursery, which had been left undisturbed for years, as bright as I ever saw it in summer. This result is effected by allowing the plants to produce seeds early in autumn, and then cutting them down close to the ground—an operation which causes them to break afresh from the bottom and form a golden-yellow, close carpet in winter. Where hardy shrubs are employed for filling up flower beds in winter, this chickweed would form an excellent undergrowth.—S.

The Striped Dead Nettle (Lamium striatum).—This plant almost merits the designation of perpetual flowerer; indeed, I have known it to be in flower the whole year through, but that was when the winter was exceptionally mild. Its beauty, however, lies rather in the variegation of the leaf than in the flower. Early in spring, and even in the depth of winter, if the weather be not too inclement, the variegation is beautifully marked. It is just one of those plants which, if instead of being extremely easy of culture demanded heat and great care, would be much prized.—J.

Wintering Dahlias.—We never take up Dahlias in winter. When cut down by frost, they are covered with coal ashes, and in April they are taken up and planted on a hot-bed with no glass over it. When the shoots are about 6 in. high, the roots are divided, and only one shoot planted in each place, prepared for it by being dug, two shovelfuls of manure being added to the soil for each Dahlia.—C. M.

Crimson China Rose.—This, planted in front of shrubbery borders or herbaceous beds, and kept pegged low, is invaluable at this time for cutting. We have only a small line of it, but we get a handful of Roses from it every other morning. The blooms, though not large, are brilliant in colour. It requires little attention after being started.—A. H., *Nottingham.*

Tropæolum tuberosum.—This is very effective in autumn, when planted so as to climb through spring-flowering and other shrubs, such as Pyrus japonica, Ribes, &c., if in a sunny position. If planted rather thickly, near the edge of a clump of Rhododendrons, it looks like a bank of orange and red flowers, till they are cut down by frost. This Tropæolum is quite hardy here; the tubers are taken up, divided, and replanted in spring, and require no further trouble.—C. M., *Dublin.*

Speedwells for the Window.—I saw in Lambeth, a few days ago, in a locality, dingy, smoky, and dirty, the Blue Gem Speedwell (Veronica) on a window-sill. It was in good bloom, and promised to continue so for some time. It is probable that the Veronicas of this type are peculiarly fitted for window purposes, as they are very hardy, and flower at a time when other plants are at rest. I have now in bloom seedlings of the pretty pale variety, and few plants could furnish more useful sprays for dressing epergnes at this time of the year than this Veronica.—A.

CULTURE OF ALSTRŒMERIAS.

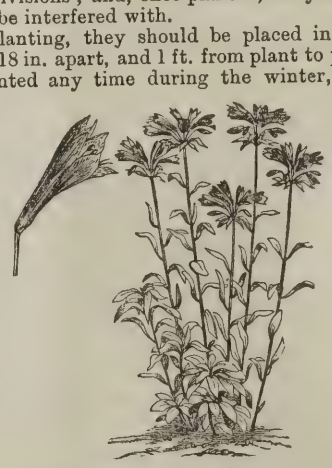
Considering the great beauty of these, and their general usefulness in the form of cut flowers, it is somewhat surprising that they are not more generally cultivated than they are, as it is only occasionally one meets with them even in large gardens. This may in part be accounted for from the difficulty there is in transplanting them successfully, and from their requirements as to soil and situation being so little understood. Being somewhat tender, it is useless attempting their cultivation, unless the bed or border intended for their reception is properly drained, so as to add to the warmth of the soil, and prevent the tuberous roots suffering from

Alstrœmeria versicolor.

an excess of moisture during winter. The best place in which to grow them is a south border, or along the front of a wall having a similar aspect, where, if the soil is not naturally light and dry, it should be made so. The best plan is to thoroughly prepare a bed for them at the outset. This should be done by digging out the whole of the soil to the depth of 3 ft.; and, in order to secure thorough drainage, 6 in. or so of broken brick, or some other good draining material, should be spread equally over the bottom of the border.

Before replacing the soil, shake over these a good coating of half-rotten leaves, or short littery dung, so as to prevent the soil from running among the interstices of the bricks, and thus stopping up the drainage. If the natural soil is at all still, a portion of it should be wheeled away, and an equal quantity of leaf soil, or other light vegetable mould, substituted; to this a barrow-load of sand should be added. The whole should then be thoroughly incorporated together previous to filling in the bed or border. The plants should be procured from the nurseries in pots, as they rarely succeed from divisions; and, once planted, they should never be interfered with.

In planting, they should be placed in rows about 18 in. apart, and 1 ft. from plant to plant. If planted any time during the winter, they



Alstrœmeria aurantiaca.

should be placed from 6 in. to 9 in. deep, so as to keep them out of the reach of frost; and, as an extra precaution, a few inches of half-rotten leaves should be shaken over the surface of the soil, so as to keep all safe. Should there be any difficulty in obtaining established plants in pots to start with, seed may be had; and this should be sown at the same distance apart as advised for the plants. The seeds being nearly as large as those of Peas, they may be sown 2 in. or 3 in. deep; and, in order to ensure a regular plant, three or four seeds should be placed in a patch. When up, the surface of the soil should be kept gently stirred, so as to keep down weeds and accelerate growth. If well treated, they will begin to bloom at a year old, and will continue increasing in strength and beauty every season, provided they receive proper attention, and are not disturbed.

When grown in masses in this way they are strikingly beautiful, as every stem furnishes a large number of flowers, and as they vary much in their colour and markings, they make a gorgeous display. While growing and blooming they should have an occasional watering, as, on account of the liberal drainage required to keep their roots in a healthy state during winter, they would otherwise become too dry, and ripen off prematurely. A good mulching of old Mushroom dung or leaf-soil is of great assistance to them while in bloom. When going out of flower the seed-heads should be carefully removed, otherwise the plants are apt to become exhausted, as almost every flower sets, and therefore such a load of seed should not be permitted to ripen. In removing the pods, care should be taken not to shorten the stems or reduce the leafage in any way, all of which is necessary to ripen the tubers and form fresh crowns for the following year. The stems should, therefore, not be cut down but should die away naturally.

Any one having deep light sandy soil resting on a dry bottom may grow these beautiful flowering plants without any artificial preparation whatever, all that is necessary in that case being to pick out a well sheltered spot, and to give the surface a slight mulching on the approach of severe weather. No trouble is involved in staking and tying, as with most plants, for the stems of these are quite strong enough to support themselves, unless in very exposed situations. Independently of the gorgeous display which they make when growing, they are quite worth cultivating for supplying cut flowers, a condition in which they last very long in perfection. S.

Fruiting Duckweed.—*Netera depressa*—Such a gay and interesting little plant as this should not be neglected by those who wish for brightness and beauty when the days are at their shortest. Many flowers which delight by their beauty of form or colours are fugitives, but in this little alpinery we have a plant which, although of minute growth, forms a fund of enjoyment all through the autumn, winter, and spring months. It grows into a dense cushion of foliage, which forms a verdant setting to numerous tolerably large, bright red berries, which are well thrust up above the leaves, and which are, therefore, conspicuous enough to render the plant of real decorative value. Were the culture of this little berry bearer difficult I would not so warmly recommend it, but as a fact the cultural action is one of the simplest, and such as anyone may master in an ordinary back yard, for it needs neither glass nor shelter of any kind throughout the growing season, but is perfectly content in a cool position in the open air, rejoicing, however, in partial shade and moisture. The shelter of a glass roof in the winter is quite enough to preserve its beauty and freshness, and it thrives perfectly well in a window in the dwelling.—J. C.

Bought Pansies.—Your correspondent "W. D.," who recommends a very excellent method of growing these flowers, remarks: "It is quite waste of money to buy what are sold in the London shops and streets as Pansy roots; no plant with such delicate root fibre could be expected to do well after the treatment they get." He is in a great measure right, but, at the same time, he is rather too despondent. The reason they do not do well is that they are taken up from the ground, with one large flower to name the plant, the earth pressed (literally) into a ball round the roots, and tightly bound round with bast and moss. These "balls," packed tightly in a box, are continually sprinkled with water, and by degrees the earth, with which they are sold, becomes sodden and impermeable as clay. As soon as they reach home they undergo three classes of treatment, as far as I have seen. 1. They are "crammed" in this glutinous earth into an ornamental vase or pot, and there left till they refuse to flower any more. 2. The ball is "potted"—*i.e.*, surrounded with good earth such as the Pansy loves. 3. The balls are entirely washed away, leaving only the clean roots, which are carefully potted in a mixture of loam, leaf mould, and sand. The first plan kills the plant in about a week. They survive the next treatment about three or four months. The last

mode is the right one, and they often live till carried off by frost, age, or "creatures." I got several good plants in Covent-garden this year, about March, and potted them on plan No. 2. I got several more in May, and potted them in mode No. 3. These last have supplied me well with flowers up till now, besides giving me several hundred cuttings. The first lot were healthy for about a month, and then got worse and worse till they died. I then turned the dead plants out of their pots, and found they had not made the least root, being prevented by the old bought ball, which was there intact, as hard as stone, in the middle of the pot. It is, therefore, this hard "dumpling," in which the roots are cased for sale, which keeps the air from the roots, and kills the plants. Let them be potted as described in No. 3, and they will thrive and succeed as well as the most carefully-raised stock.—GIROFLE.

Pansies In Towns.—With regard to the remarks of "W. D.," on p. 448, on the above subject, I may say that, as I have distinctly stated, the directions in my paper are calculated to apply to situations in the heart of towns, not to suburbs like Peckham, which is, compared with many places, almost rural. In Peckham Roses will grow and do well, as well as many other subjects which would inevitably fail a mile farther in, and Camberwell-green is only a short distance from Denmark-hill, which is quite open and healthy. In both these places—or at least in the greater portion of both Peckham and Camberwell—I have no doubt that Pansies would do fairly well, with care; and, indeed, I have included them, as likely to do so, in my second list, under the name of Heartsease—which list contains the names of such plants as would do well with care, or are more suitable for culture in suburban gardens. In my garden, which was more than a mile nearer St. Paul's than any part of Peckham, I tried all kinds of Pansies in all manner of ways, and though a few good blooms would sometimes be produced just at first, yet they always dwindled, and ultimately perished. If they can be made to succeed at all, of course the method given by "W. D." is much the best—viz., to raise seedlings oneself, and so avoid any serious change or check. I always recommend this method of raising seedlings, especially for town gardens, for all kinds of plants to which it can be applied. Nevertheless, though I allow that Pansies may be grown—and, with care, grown well—in any small town, suburb, or near a large city, yet I maintain that there are many other plants that will do better, and with less trouble, in town gardens, than Pansies, as a general rule. Of course there are exceptions, but I do not consider that the fact that plants, which were probably raised in a healthy country nursery and carefully replanted, looking well for a few weeks or months, proves that they may be grown well in such a situation.—THE AUTHOR OF "TOWN GARDENING."

Scale on Plants.—Paraffin, mixed at the rate of a small wineglassful to four gallons of water, will kill scale, and does not appear to harm the most tender foliage. If mixed with hot soft water it will mix better, and be more effectual than if applied cold. With hard-leaved plants, such as Epacrises or Camellias, the heat of the water may be quite warm, as in passing through the syringe and air in applying it cools down considerably, and the hotter it is, so as not to endanger the safety of the plants on which it is used, the more satisfactory will its effect be, and the same may be said of all the insecticides. In using paraffin for the purpose of destroying scale, &c., the water should be kept constantly agitated either by rapid stirring or, better still, by some one taking up a syringeful and returning it again with force into the vessel, so as to drive any paraffin that may, from its greasy nature, be floating on the top into the water, and while this is being done a second person can be putting it on with another syringe. If not managed in this way its distribution is likely to be very irregular, from the cause already specified, and therefore some part of the plants would get more than their share and of greater strength than would be safe for them. The plants should, when applying it, be laid on their sides and left in that position to drain for a time, in order that none may get into the soil.—S.

THE SHRUBBERY.

Berberries in Hedges.—I was visiting a place some time ago, and was very much struck with the appearance of a fence-hedge which extended the east and south sides of a kitchen garden. There were two acres walled in, and one acre around the outside of the walls which this hedge protected from sheep which were in the adjoining field. It was planted with the common White Thorn, intermixed with Berberis Darwinii, and as it had been well clipped-in every year, it formed quite a thicket, and rendered good protection from the cutting east winds, besides being highly ornamental. Some of your readers, I dare say, know more about its properties, as it was quite foreign to me; but the plants of the Berberis Darwinii being easily raised from the seed, and by transplanting at the proper time, I don't see why it could not be introduced more into our boundary and field-hedges, which look so bare in winter, and give but very little protection.—KIRKTON.

How to Grow Veitch's Virginian Creeper.—Most persons who have seen Ampelopsis Veitchi must acknowledge its merits, but its beauty may be enhanced in a tenfold degree by allowing about three stems to grow, and cutting off all the side shoots close every spring, when young ones quickly grow out, covering the wall with a delicate foliage which is frequently mistaken for some new and beautiful Ivy; these branches, although so tender-looking, last an astonishing time in vases or worn in the hair.—C. E. I.

Cut Spray of Alstrœmeria puliferum.

Escallonia macrantha in the Midlands.—This is one of the best evergreen shrubs which we have for planting against terrace walls having a south or west aspect. It grows freely in loam mixed with a little sand. When in good health the foliage is of a bright and cheerful tint of green; and, when in full flower, it is very effective and useful for cutting purposes. E. Ingrami is another good variety; both are quite hardy here, having stood unprotected for six years.—A. H., *Nottingham.*

Cherry Plum as a Hedge Plant.—The Myrobella Plum is especially valuable as a hedge plant on account of the vigour with which it grows in all kinds of soil, even in the poorest and most exhausted, its hard, unyielding wood, its long, sharp spines, and its great hardiness and non-liability to disease. It grows fairly well under trees, but, of course, not so well as in more open positions. It comes into leaf much earlier in spring, and retains its foliage much later in the autumn than White Thorn. This adds greatly to its value for ornamental purposes. It may be treated, in planting fences, in all respects like White Thorn, except that it is not necessary to plant it so closely; from four to six plants per yard are sufficient for ordinary purposes. If a strong fence be required very quickly the plants should not be cut at all during the summer. They should be shortened to about one-third of their height at planting time, and each succeeding winter, or time when they are devoid of leaves, they should be shortened to within about 9 in. of the height to which they were cut the previous season till the height which it is desired that the fence should ultimately attain is reached. It may then either be clipped in the ordinary way as appearances require, or the superfluous shoots may be trimmed off every winter. This Plum is also valuable as an ornamental shrub or small tree, and as a stock for the Apricot and Plum it is invaluable, succeeding so well as it does on poor soils.—J. E. E. *Norwich.*

Trees for Screens.—One of the first conditions that most people desire in a garden is privacy; whether the garden be that usually attached to a small villa residence, or of a more pretentious character, one of the first things ordinarily looked to is the planting of the boundary lines to, as far as possible, exclude the sight from outside except at such points as it is desirable to leave open to afford views from the interior of objects more or less in the distance, as local circumstances may determine. In the case of large places, this is easily managed where there is sufficient room to introduce a belt of deciduous and evergreen trees, which should be skilfully arranged so as to effect the object without making the intention more than can be avoided apparent; but with amateurs' gardens of an ordinary size there is more difficulty in making an effectual screen without its occupying too much land. Erect-growing Poplars, from the limited space which they cover, and their rapidity of growth, are most frequently used, yet these are unsatisfactory, inasmuch as divisional lines of this sort should

be as impervious to the eye during winter as they are in summer, a condition which cannot exist when deciduous subjects are used. Much better every way, both by their ability to thoroughly answer the purpose in view, winter and summer alike, as well as thriving well in most soils and situations where not exposed to too smoky an atmosphere, are such things as Pinus cembra, Pinus austraiaca, evergreen Oaks, and Hollies; these, by a judicious arrangement in not planting them in exactly straight lines, with a few dwarfer-growing subjects in front, such as Rhododendrons, Portugal Laurels, and Aucubas, will make an effectual screen in a short time if the plants be sufficiently attended to, and the soil fairly enriched. It is a prevalent, though very mistaken idea, that such plants as these do not like an enriched soil in which to grow; this, however, is anything but the case. Green, rank manures do not suit them, but a fair admixture of that which is well decomposed stimulates their growth amazingly. In the case of all plants required for screens, it should ever be borne in mind that they must always have enough space to keep the lower branches in a healthy, thriving state, otherwise they get naked below, which completely defeats the object in view. With trees so grown for such a purpose, a moderate use of the pruning knife is admissible, in order to prevent their unduly encroaching upon each other, and to encourage and direct growth where it is most required. Not only is the boundary line of a garden, composed of evergreen subjects like the above, much more effectual for the purpose intended, but it has the additional advantage of looking well at all seasons, and affords much more protection to everything requiring shelter during the winter and spring, at which time it is most needed, than can possibly be effected by trees and shrubs that cast their leaves.—B.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

December 6.—Sowing Mignonette in pots, and keeping it slightly warm in pits, so as to have it ready in time for the London season; potting Spiræas for forcing; planting Tritoma Uvaria, Phloxes, Hyacinths, Narcissi, and double scarlet Anemones; also standard Roses where required, and a hedge of Berberis asiatica; likewise Cypripedium pubescens under hand-glass out-of-doors in well-drained peat, and covering with a layer of leaves as a protection from frost; cleaning orchard-house, giving water before manuring, and again after, then soiling over all, and treading firmly; making a border ready for Parsley sowing; manuring young Apple trees; pruning espalier Apple and Pear trees, and re-tying them.

Dec. 7.—Putting in to force third batch of Asparagus; beginning to thin plantations, paying especial attention to specimen trees. Plants in flower—Hyacinths, Lily of the Valley, Narcissi, Mignonette, Heliotropes, scented-leaved and scarlet Pelargoniums, Poinsettias, Fuchsias, Primulas, Chrysanthemums, Schizostylis coccinea, Amaryllises, Tulips, and Coleus.

Dec. 8.—Digging all vacant spaces; finishing the trenching of borders for fruit trees; putting Endive weekly into slight heat to blanch; placing below greenhouse stage all bulbs which have finished flowering in order to save them for planting out-of-doors for cut flowers; covering up some Rhubarb in the open ground; making a two-light bed for Carrots and Radishes; putting Ranunculuses in pots into cold frames.

Dec. 9.—Potting young Cucumbers, and putting them into a small frame; keeping Black Prince Strawberries at from 55° to 58° by night, so as to have them ripe about March 13; putting Iresine Lindeni into heat for cuttings; moving Coleus from pits to shelf of early Vinery; taking up Lettuces from under wall and putting them in frame; tying up Vines which were bent down in order to induce the rods to "break" regularly.

Dec. 10.—Potting Tuberoses and placing them in heat; putting Gloire de Dijon and Maréchal Niel Roses into good-sized pots for flowering in conservatory. Planting Laurels and Yew trees; getting Camellias into conservatory; putting Roman Hyacinths which are in flower into greenhouse; top-dressing Cucumber plants with loam and manure, and pressing it down firmly; Camellias and Narcissi coming well into flower, also a few pots of Lily of the Valley.

Dec. 11.—Beginning to surface-dig herbaceous borders; potting Pelargoniums; putting first batch of pot Roses into heat, and keeping them at 55° at night; protecting Peas from sparrows by means of Asparagus haulm, which not only serves to ward off frost, but lies so lightly that the young Pea shoots grow right through it; making trenches round Wellingtonias, and filling them with good soil; giving a top-dressing of new soil to Vine border; wheeling pond-mud on to Raspberry quarter.

Glasshouses.

Winter Arrangement.—There are few more effective plants for conservatories than Tree Ferns, and even where the temperature of a conservatory is kept no higher than that of an ordinary greenhouse, there need be no hesitation about placing Tree Ferns in it. The arrangement of these and other plants of a similar description must necessarily be dependent upon the character of the house. Where objectionable central stages exist, such subjects can never be made effective, as the pots or tubs in which they are grown have to be elevated, and are thus brought too prominently before the eye; and, unless the house is a high one, the heads of the plants are in too close proximity to the roof, which not only interferes with their appearance individually, but spoils the general effect. Such kinds as Dicksonia antarctica, the more elegant D. squarrosa, Cyathea dealbata, or Alsophila excelsa, all species that form compact, moderate-sized heads, may be used in conservatories of not more than medium size, so as to form centres of groups, which are much more effective than the often adopted method of filling the middle of the house with a large single mass of plants. The great advantage resulting from dispensing with centre stages in conservatories, or beds in which the plants are planted out, is that it admits of the arrangement being so varied from time to time as to give the whole a completely different appearance, so much more desirable than the continuity of the same plants always in the same places as when stages are used. Even in the dull season of the year an eye that is trained to effective arrangement will, with limited and common-place materials, often make a conservatory or greenhouse look better than where more valuable plants with more flowering subjects are at command. But in all this kind of grouping it is necessary to prepare much larger numbers of plants that are made to do subordinate duty in edging the groups than under ordinary circumstances, especially in the case of winter plants, such as Primulas, Roman and large-flowered Hyacinths, Narcissi, Hoteia japonica, forced Lily of the Valley, small shrubs (such as Deutzias, Azalea amœna, and double Prunus), Richardia æthiopica, Spiræa palmata, Amaryllis, and anything of a similar somewhat taller character, with enough green material, such as Adiantum cuneatum and hispidulum, Pteris serrulata and P. cretica albo-lineata, Isolepis gracilis, and Selaginella, all of which it is necessary to grow in greater quantities than for the promiscuous style of plant arrangement, beyond which at one time little was attempted.

Cyclamens.—Where Cyclamens are well grown with the last year's sown plants kept on continuously warm with something like an intermediate temperature, these will now through the winter months play an important part in the arrangement of conservatories and greenhouses that are kept tolerably warm, without which plants that have been grown with some heat cannot be expected to continue long in good condition; but to do justice to these plants they require keeping near the glass, so as to have plenty of light. Movable wire stands are very useful wherein to group plants of this character, which, if relieved by a few of the hardier kinds of more elegant leaved Palms or other green-foliaged plants, do much to enliven the general appearance. There is one thing in reference to the management of conservatories at this season of the year of which it is well to remind the inexperienced, and that is the necessity for doing something to prevent the atmosphere getting too dry. This is a matter which requires to be carefully managed, so as to avoid the extremes of too much moisture, which is objectionable in many ways, and the dry arid atmosphere that never fails to cause the premature dropping of Camellia buds.

Watering.—Simple as this operation is, it will nevertheless be found that in a mixed collection of plants moderately varied in character it requires a good deal of attentive observation to give to the whole water in such proportion as may be required, for, although general rules may be given, yet to generalise too far in this direction is sure to lead to serious mistakes, as there can be no question that the state of the roots as to the moisture required, quite as much in the winter as in the summer, always depends upon the conditions under which the plants exist in their native country in the different seasons of growth and rest; for instance, Azaleas, coming as they do from the moist hill districts of India, though very fine, somewhat delicate-rooted plants, will not bear without injury the soil being kept nearly so dry as plants from New Holland or adjacent parts of the world, whilst many of these in turn need more water than some of the Cape species, particularly Heaths. Those, therefore, who have not had much experience in the cultivation of mixed collections of plants will find that they will be abler to form a correct estimation of their requirements, by in this way determining the more or less moist condition in which they should be kept, than by being led alone by their hard or soft-wooded character. Taking plants collectively, both those that require keeping the driest, and also those that want the most moisture, there will obviously not be, in the winter season, danger of absolute death through their being kept a little too dry, as there is from a similar cause in the summer when growth is in an active state; yet where plants naturally need the soil about their roots being kept comparatively moist, when they receive an insufficient supply they get into a languid condition that enfeebles them so far as to prevent their making nearly the progress they ought when the season of growth comes round.

Primulas.—The single varieties of Chinese Primulas have become much improved of late years, but still no attention to seedling raising has the effect of removing the disposition to damp off in the winter months, which there seems to be only two methods of avoiding. Of these the best is keeping them through the winter in a temperature higher than that of an ordinary greenhouse, say from 45° or a few degrees higher at night in a light position. Thus situated, with a little more warmth in the daytime, there is not much to fear from the effect of damp, and they may have sufficient water given to enable them to keep on growing and throwing up flowers; but when in greenhouses where little more heat is maintained than just enough to exclude frost, they need to be kept close up to the glass, and should receive no more water than is required to prevent the soil from getting so dry as to stop all growth. Where there is a chance of treating them in the former way they will produce double the quantity of flowers; yet at the best the single varieties are of little use for bouquet or button-hole flowers, as compared with the double kinds, in which there is now even greater improvement than in the single ones. The facility with which the single varieties are raised from seed to that of the double sorts, needing, as the last do, to be increased by cuttings, is the cause of the double ones being so much less grown than they deserve to be. The fine forms of these that now exist are such that wherever there is a continuous demand for cut flowers, and means of keeping them something warmer than a greenhouse through the winter, they should be extensively cultivated. The best forms, now in the colours of pink, pure white, blush, and white slightly flaked with pink, have flowers almost as large as an ordinary Pink (Dianthus). The advantage in their use for cutting is that they will keep fresh for days, whereas the blooms of the single varieties are so liable to fall off that no dependence can be put on them in any arrangement of cut flowers.

Schizostylis coccinea.—Those who grow in pots a good stock of this handsome late autumn-blooming plant cannot fail to have noticed how useful its bright scarlet spikes of flowers are through the autumn months. It blooming will in most cases now be nearly over and although the plant is hardy, still in common with anything of a similar nature that has been kept in a warm greenhouse through the autumn, it is better not turned out of doors, but should be moved to a cold pit or frame, and there have the pots plunged in ashes.

Flower Garden.

Auriculas.—It is still necessary to look over the plants in order to remove all dead and decaying leaves. Apply water to prevent the soil in the pots becoming quite dried up. Place mats over the glass when the frost is very severe. Admit plenty of air; in fact, remove the frame lights whenever the weather is at all favourable. There is some difference of opinion as to the position in which the frames should be placed. Most growers prefer them to face south or south-east, but much, of course, would depend upon the time when the plants would be wanted in flower. If the bloom is wanted to be at its best by the middle of April, let the frames fa

the south, but if not wanted until nearly the end of the month, let the back of the frames be placed to the south.

Carnations and Picotees.—When the plants are fairly established in cold frames they do not require much water at present. If they are looked over about once a week, and those plants that require water are carefully attended to without wetting the leaves, they are not likely to be injured by the disease called spot, which is usually engendered by too much moisture in the frames during the shortest days of the year. There are some sorts both of Carnations and Picotees that are seldom or never attacked by spot, while others seldom escape that disease if the surrounding circumstances are favourable to its attacks.

Dahlias.—Where the roots of these have been stored away, it is necessary to look over them occasionally to see that the crowns of the tubers are not injured by damp caused by the stems decaying. If this has happened, the decaying portion must be carefully removed, and the root thus affected should be taken out and placed in a light airy position to dry. All that is required is to keep the tubers in a comparatively dry place where frost cannot penetrate.

Phloxes and similar plants in pots are now comparatively at rest in cold frames. It is best to plunge the pots in some rather dry material, such as fresh Coca-nut fibre refuse, which answers as well as anything for the purpose. Plenty of air should be admitted, removing the lights when it does not rain, the same as in the case of Auriculas.

Cold Frames.—It is well known that where very choice collections of herbaceous plants are grown it is desirable to winter a portion of them in cold frames. The plants ought to be established in pots before the winter, and then it is desirable to plunge them in some light material. We devote a frame or a portion of one to choice species of Primula. In the same frame are Ixias, Anthericum Liliastrum, Meconopsis, Trilliums, and, indeed, any plants the whole stock of which it is not desirable to risk in the open garden. These plants will not take care of themselves, nor do they require much attention. All that is needed is to look over the pots about once a week, and water such as require it. The frames ought also to be freely ventilated.

Fruit.

Vines.—Early Vineries that have outside borders will need protection, consisting of a covering of dry Fern or leaves in sufficient bulk to exclude frost, and sashes or shutters to throw off snow and rain. The Vines in succession and midseason houses will now all be ready to prune, and the sooner this is done the sooner will they go to rest. If they have been infested with insects, remove from the stems the loose bark only, and then paint or wash them over with a strong solution of Gishurst or soft soap and sulphur. The removal of the outer bark of the Vine is only recommended in order that the insects may be the more easily reached by the wash; where insects have not been troublesome, by all means leave the bark intact, for its removal, to say the least, is most unnatural, and must in some degree prove injurious. Late houses still require careful management in order to keep the Grapes in good condition; besides keeping the atmosphere as dry as possible—not arid—it is necessary to keep the temperature from ever falling so low as that outside, which on some mild days might be the case if not closely watched.

Figs.—In the culture of Figs there are two conditions essential to securing the best returns; the first is restricted root space, and the second is liberal maturing; the first ensures fruitfulness, and the second is necessary to its more perfect development; hence arise the generally satisfactory results that are obtained by growing Figs in pots, a plan that cannot be superseded for early work, but for general and late crops much more and finer fruit can be had by planting out. Of course, the size of borders must to some extent be ruled by the space there is for the spread of the trees, but, as a general rule, 2 ft. in depth and 6 ft. in width will be found to be ample. Provision for surplus water to readily pass away should be made by the concrete or paved bottom being made to slope to the drain in front. The soil in which Figs revel is a chalky loam, to which may advantageously be added charcoal and a small proportion of ½-in. bones; it should be made firm, for in a loose, spongy soil the trees are apt to grow too robustly. When once the borders have become full of roots the annual removal of the top soil will be necessary, for the purpose of adding fresh feeding material, and the disturbance which the roots thus get gives a salutary check to any disposition that the trees may manifest towards too vigorous a growth. Now is the time to apply such top-dressings, and also to place a portion of the trees in pots in gentle warmth. Bottom-heat is not necessary, but time will be gained if this can be afforded by plunging the pots in Oak leaves, in sufficient bulk to engender a heat of 65°. The leaves will give off sufficient moisture, therefore the plants will not need syringing, and for the present fire-heat will only be required when the temperature is likely to fall below 45°.

Strawberries.—To have ripe fruit early in March, which is quite as soon as the fruit is good, a number of plants should now be started. Where there is no house specially devoted to their culture, one of the best positions for this early batch is a pit filled with Oak leaves, on which the plants should be set (not plunged) closely together; the warmth and moisture given off from the leaves soon causes new root action and expansion of the crowns. Caution is requisite that roots do not protrude and get established in the leaves, as before this takes place they should be drafted on to shelves in Peach-houses, Vineries, &c., and others put in their places. Whilst in this position they may require water about twice a week, but no syringing will be requisite, the moisture from the leaves being ample. A little ventilation will be necessary in all weathers, but when mild give air liberally. We always select 100 of the finest plants for the first introduction; half the number would be abundant, could we depend on all of them setting and swelling off their fruit well, but at this early season it is always advisable to allow a wide margin for failures; therefore start plenty, and keep selecting the best plants; the weakest ones will do good service at the end of the season.

Vegetables.

In districts where the common Bracken is plentiful protection from frost becomes a very easy matter, as there is no better material for covering Celery, Cauliflowers, and early Broccoli; the lightest sprinkling of it over the plants wards off many degrees of frost, and, what is of great consideration in some gardens, it does not present that untidy appearance that stable litter does, which is the next best protecting material. All heads of Broccoli or Cauliflowers that are anything like fully grown would be best lifted entirely and taken under cover. They keep good for weeks either heeled in or suspended head downwards in any cool shed from which frost can be excluded. Lettuces and Endive may also be protected with Bracken, but those that are required for winter salads ought always to have the protection of frames. Cauliflower and even Cabbage plants will be the better to have protection in severe weather. Parsley is best protected with mats resting on hooped sticks or Pea sticks laid over the bed. Of course all such protection should only be employed when the weather is really severe, and should at once be removed when it has become more favourable.

After hard weather it is necessary to go over plots of Brussels Sprouts, Cabbages, Savoys, and Kales, and pick off all the decayed leaves, which not only smell disagreeably, but hinder the admission of air, which is most essential to keep such green crops in a sturdy condition. When the weather renders it impracticable to work on the ground, compost and manure heaps may be turned over, leaves and stable litter got together for making hotbeds for forcing purposes, and drains opened, ditches cleared, hedges clipped, and advantage should always be taken of dry, frosty weather to do all heavy wheeling or carting, for such work is then not only the more easily and expeditiously done, but there is no after repairing of walks required, as is the case when the traffic takes place under less favourable conditions, and thus "labour saved is labour gained."

Rhubarb and Seakale give least trouble when the roots are lifted and placed in a Mushroom house, but the want of such a place need be no drawback, as it will do in any shed, cellar, or outhouse, only, of course, the warmer the situation the sooner it is ready; in cool places time may be gained by always watering with warm water at about a temperature of 90°. It may be forced in the open ground by placing over the crowns, pots, tubs, &c., and using leaves only as a heating medium, as the addition of litter renders the heat too violent.

Seakale is amenable to exactly the same modes of forcing as Rhubarb, except that extra care is necessary to exclude light and air to blanch it well. Beans and Asparagus forcing pits that are specially constructed and heated with hot-water pipes are, of course, the best in which to grow Asparagus; but a bed made up of leaves and a small proportion of stable litter, with frames placed on it, or a similar bed made up on the floor of a Vinery that is being forced, serves the purpose well. A bottom heat of 75° should never be exceeded, and a top or surface heat ranging from 45° to 55°. For the forcing of French Beans—even when there are pits specially constructed in which to grow them—there is no better plan than having them in pots, as they can then be moved at will, and the crop advanced or retarded as may be required, and a constant succession is far more easily maintained by making a sowing fortnightly in quantity according to demand. One important item in their culture is that they are moisture-loving, and should never suffer from want of water either at the root or in the atmosphere.

Carrots and Radishes force well when sown on a bed of sufficient massiveness to produce a bottom-heat of 65°; glass coverings are, of course, indispensable, but when the weather is mild the fullest exposure is necessary. If the two crops are sown in alternate lines 6 in. asunder, the Radishes will come off before they are in any way detrimental to the Carrots.

GLASSHOUSES AND FRAMES.

Vallotas in Winter.—These are too frequently subjected to a drying process, a course that is most detrimental to them, as then they have most of their large fleshy roots, whereby they are considerably weakened. As plants of these are now in a less active state than at any other time, what re-potting or division they require had better be done at once; they may be shaken out from the old soil with as little injury as possible. Vallotas do best in a mixture of loam, sand, and leaf-mould, in which they should be potted somewhat firmly in well-drained pots, and afterwards stood on the hard floor of a pit close up to the glass, or on the back shelves of a greenhouse; but the former position is the most suitable, as they remain in a more uniform condition of moisture than when exposed on dry, airy shelves. In wintering Vallotas the soil should be kept just moist enough to preserve their leaves in a healthy green state and the bulbs plump and solid, a condition that enables them to flower better than when dried off in the ordinary way. If potted singly, from 6-in. to 8-in. pots will be found to be sufficiently large, and if the bulbs be small, three in the latter size produce the best effect. Any offsets that may be taken from them during the process of re-potting may be planted out in prepared beds in frames, or potted thickly in stove pots or pans to grow on for future use.—S.

Ixias, Sparaxis, Babianas, &c.—For pot cultivation there are few bulbous plants more beautiful or generally useful than Ixias, Sparaxis, and Babianas, all of which are alike valuable either for greenhouse decoration or supplying cut flowers. Although perfectly distinct in appearance, they require the same treatment, and should at once be potted in rich, sandy soil, and kept close under cover of a cold frame or pit plunged in coal ashes, where all the attention they require till they get into leaf is to preserve them from frost and vermin; 6-in. pots are quite large enough for them, and in these from six to twelve bulbs should be planted, according to the strength and size of the different varieties. If the soil be in a moderately moist condition, as it should be at the time of

potting, no water will be required till they have started well into growth, and even then it must be given but sparingly. All the above are nearly hardy, and any small bulbs there may be on hand can be planted on dry sunny borders, in light sandy soil, close under walls, and will be found most useful for cutting after those in pots in the greenhouse are over.—J.

Tritonia aurea.—As an autumn-blooming plant the Tritonia is one of the most serviceable, and affords a shade of colour that we stand much in need of at that season for associating with Achimenes, Zonal Pelargoniums, &c., with which it blends well and forms a very pleasing contrast. Where fine masses of this are required the roots should be disturbed a little as possible after they once get established. The best way to treat them is simply to reduce the ball by removing as much of the old soil as can be done without breaking the rhizomes, and then to shift them into a larger-sized pot, using good fibry, mellow loam for the purpose. In cases where an increase is desired they should be shaken out, that they may be divided in the most advantageous way, and when potted, placed in any cold frame where they can be well attended to with the syringe after they get into leaf to keep down red spider, an insect to which they are particularly subject.—W.

Fuchsias.—In order to obtain early cuttings of these, it will now be necessary to get a few old plants into heat to induce them to break. Almost any place where there is sufficient moisture will do to give them a start, after which they must have a light, airy position to induce a firm, short-jointed growth. Any that were struck in the autumn should be grown steadily on by affording them the requisite pot room as they advance, and a temperature from 50° to 60°, according to the state of the weather. It often occurs that old plants laid by in sheds or other draughty positions out of sight are allowed to become too dry, and when this takes place, many of the branches die back to the main stem and even down to the roots. To save any loss this way the pots should be plunged in damp ashes or some littery material to prevent the dry air from playing upon them.—W. P.

CINERARIAS.

Now that these will soon be coming into bloom a few notes on their general treatment and improvement may be of interest to many readers of GARDENING. Of all plants grown for general decorative purposes Cinerarias are the most useful, and more particularly is this the case as regards amateur cultivators who have only a limited amount of house room, as the Cineraria is a plant that does exceedingly well in pits and frames. Indeed, if these be of that substantial character which they usually are when built with bricks, no better place can be had for growing them; and if a single hot water-pipe runs along the front wall for the purpose of drying the atmosphere when necessary and to keep out frost, the situation will be perfect, and it will exactly meet all their requirements.

Anyone, therefore, having the convenience of such a structure, will have one of the most perfect, not only for growing Cinerarias, but also many other plants for keeping a greenhouse gay during the winter and early spring months, as the same temperature will just suit Cyclamens, Lachenalias, Libonias, Eupatoriums, and a host of such plants that come in about the same time, but which, until they get into bloom, are not easy to manage among others, where they have to stand far from the glass and are crowded for room.

Sowing, &c.—Valuable as Cinerarias are in spring, they are doubly so at or soon after Christmas, at which time they may be easily had by sowing seed in April, and growing the plants on during the summer in a cool, shady retreat, so as to keep them free from the attacks of red spider. The best way of raising them is to fill pans with light, rich soil, consisting principally of leaf-mould or peat finely sifted and pressed down level and smooth. Before sowing, however, this should be watered through a fine-rosed pot, and then allowed to stand and drain for a night or so to get rid of the surplus moisture. Seed of such a delicate nature as that of the Cineraria should never be watered till the young plants are found to be peeping through the soil, and the necessity for this may be obviated by covering the pans with a sheet of glass, and laying a little moss or a piece of brown paper over that, so as to shut out the light and sun; but, in all cases in which this is done, much watchfulness is needed to remove these coverings directly the young plants make their appearance, as a day's confinement in the dark will be sufficient to draw them up to that degree as to weaken them very considerably. In order to facilitate the handling and pricking off, as well as to prevent the plants from becoming "drawn" from being too near each other, the seed should be sown thinly and slightly covered with silver sand and fine soil in about equal proportions, and if then placed where it can get a gentle moist heat, the young plants will soon be through, after which a shady place near the front of a hotbed or the back shelf of a warm greenhouse is the best place till they are large enough to pot off singly, and when this is done they may be transferred to any cool frame where they can be kept close for a short time to give them a start.

Soil and Situation.—Although Cinerarias will grow in almost any kind of soil, they delight in that which is rich and light; and if a mixture of about equal parts of loam and leaf-mould, together with little decomposed cow manure, be afforded them, they will be found to flower stronger and better than in anything else. A pinch of soot at the bottom of the pot, or a little mixed up in the soil, is a great help to keep them in health and add to the size and deep green colour of the foliage, besides which, being disagreeable to worms, it is desirable on that account. During summer we select a shady site for them near a building or where a large tree casts a shadow; on this spot we place a three-light box, and then put in 3 in. or 4 in. of coal-ashes to form a firm bottom for the pots to stand on. A situation of this kind is always better than a more open one, as the shade is natural to them, and they get more light than could be had if the sun's rays have to be screened by mats or other means, and it often occurs when these are used that they are not on when most wanted, or that they remain on long after they ought to have been removed—thus damaging the plants by causing the leaves to come thin and flimsy. In a naturally shady position there is no fear of this, and they may be grown much more successfully with far less labour and attention than they require anywhere else. The same remarks apply to Chinese Primulus, which, during the summer months, should be grown and treated in a similar manner.

Modern Cineraria.

Watering.—An important point with both is to surround them with an atmosphere saturated with moisture, and this may be secured by copious syringings overhead, or gentle watering through a fine-rosed pot every afternoon before closing. These repeated applications will saturate the ground under them, and keep it in that desirable condition throughout; and if this be done, the growth of the plants will be rapid, and there will be no difficulty in maintaining them in the most perfect health, provided they are shifted on from time to time as they require more pot room. This is one of the most important matters in the cultivation of Cinerarias, for if they be allowed to remain stunted from want of root-room till the flowering period arrives, or suffer from an inadequate supply of water, they are never so fine or have anything like the sized leaves and quantity of bloom they otherwise would have. The great thing with these, as with all other so-called soft-wooded plants, is to keep them growing right on without a single check, so as to insure a full and free development of deep green healthy foliage, without which they can never be regarded with satisfaction.

Insects.—Besides being subject to red spider, Cinerarias are likewise liable to attacks of mildew and green fly, the latter of which is frequently troublesome, and can only be destroyed by repeated fumigations with tobacco, This is a work that requires great care, as no plants are more easily injured by overdoses than Cinerarias, and therefore the fumigations should only be light at one time, but repeated again and again after a few hours' interval till the insects are dead. From want of caution, and not using it in this way, I have seen a whole year's labour and attention lost, and no doubt this has been the experience of many, both as regards Cinerarias or other plants, as few escape such mishaps at some time or other, especially if tobacco paper be burned instead of the genuine article.

Saving Seed.—The sportive tendencies of Cinerarias are so great that there is sure to be a marked difference in the quality and size of the flowers of a batch of seedlings; therefore, when the plants are in bloom, it is a good plan to go over them and pick out any that show special merit, in order that they may be placed somewhere apart from the rest, as it is only by thus isolating them that they can be kept pure, or any improvement effected. In cases where it is desirous to perpetuate any particular kind and increase the stock, it may easily be done by saving the plant, which after it has done flowering should be turned out of the pot and plunged in leaf-soil in a cold frame, where, if kept duly syringed and attended to, it will soon send up a quantity of suckers around the base. These form the future plants, and should be taken off as soon as they have made sufficient root to support themselves. They should be potted singly in 3-in. pots, and afterwards treated precisely the same as seedlings. Years ago few seedlings were grown, and even the named varieties of that time would now be thought little of, so great (as shown by our illustrations) has been the improvement that has taken place in these popular flowers. It is no uncommon thing at the present day to see them with broad thick petals overlapping each other, forming individual blooms larger than a two-shilling piece—a striking advance compared with what they used to be. The new race of doubles that caused such a stir have disappointed many; but, considering what has been done with Cinerarias during the last quarter of a century, there is reason to hope that we have not yet reached the limit to which they may be brought. All progress, however, must be made by seeding from the very best, flowers and no other, and if this be done constantly we may look for still better results in the way of fine blooms.

The accompanying woodcut will give an idea of what the flower of the modern Cineraria are like, whilst that on the opposite page represents a spray from a plant, interesting as being one of the species from which the popular hybrid races of Cineraria have been produced; and it is also interesting to observe the improvement which has been effected in the modern "strains" with regard to the size of the flower-heads, the breadth and length of the ray florets, and the symmetry of form. This species is much earlier in flowering than the ordinary varieties; therefore it is desirable on this account. The colour

of the flowers is a bright purple, and it is altogether a showy plant.

Tuberoses.—These are sold in three varieties: the Italian, the African, and the American Pearl. These last are very dwarf free-bloomers, but the best (and most expensive) are the African. The treatment I pursue, with some success, is as follows:—Plant them in pots, the crowns just showing above the earth, in loam and leaf-mould well sweetened, with a very little peat added. They may be started at any time of the year. As I grow them solely for button-hole purposes, I get them by the half-dozen, and plant one every ten days, and so get a very good and regular succession. Water the plants to settle the soil, and plunge them in a hot-bed, keeping them there without water till they are about 5 in. high. Some growers cover the plants in the hot-bed with cocoa-nut fibre, and though I do not pursue this plan myself, I have no doubt that it is an excellent way. When the plants are 5 in. high I bring them into the conservatory, watering seldom but freely, till the flowers expand, which is generally about two months from the time of starting. I give a night temperature of about 40°—45°, and I always have three or four fully-expanded blooms.—Girofle.

Deutzia Gracilis.—This is an excellent plant for an amateur, for the simple reason that it is so accommodating. Last spring I had in my cold greenhouse four or five well-established plants in 24-sized pots that had been growing in these for two years without a shift. They were wintered without special care, and, as soon as growth set in, the plants were treated to occasional doses of "Clay's Fertiliser." They broke out into a prolific bloom, and were the admiration of all who saw them. This is, perhaps, a haphazard way of doing work, and not to be commended generally. The facility with which this most useful hardy shrub can be cultivated, and the constancy and freedom with which it blooms, makes it a great acquisition to our gardens, though there are many in which plants of much inferior value are grown, while this is overlooked. Deutzia gracilis has one great advantage—it will flower in a young state, and we have seen plenty of it in pots quite tiny in size that were blooming with remarkable freedom. As a pot-plant, its cultivation is simple. It requires to be potted in light soil, moderately rich, in order to encourage a free and healthy growth. One main point in the cultural process is to ensure healthy, well-ripened wood at the proper season, as it is then the dormant flower-buds are formed. It must not be supposed that it requires heat in order to get it into bloom; but with the assistance of heat it may be got into flower any time during the winter and early spring months, and in heat, with a gentle stimulant in the shape of some weak manure water, fine flowers are produced. Then the plant will stand in perfection a long time, if kept a little cool and not too much exposed. The plant can be propagated by cuttings or by division. A well-grown and established plant makes a free growth, and if the plant be divided after flowering, and planted out in good free soil, the divided parts will soon grow into strong plants, and be very useful. They should be allowed to grow in this way for one whole autumn, winter, and spring, and be potted the following autumn. It should be borne in mind that in forcing the plants the shoots should not be cut in in any way, or a loss of blooming wood will result. It is best to cut back the long or decayed wood after blooming, at the same time thinning out the weak shoots.—R. D.

ROSES.

CLIMBING ROSES.

The desire for the varieties of Roses that produce the finest formed individual flowers is so contagious, that in far the greater number of gardens many of the Roses best adapted for particular purposes are completely lost sight of. Even where lists are given of what may be termed garden Roses, it rarely happens that there is anything to be found in them but a selection of the freest-growing Hybrid Perpetuals, with a few Noisettes, Bourbons, &c., a whole host of distinct kinds being left out much more appropriate for planting in many positions in any garden—large or small—than those recommended. Take, for instance, the Banksians, both white and yellow. What can be more beautiful than the innumerable bunches of full, yet not formal, flowers that these produce when well established in a warm situation? but how comparatively rarely are they seen! All they require is either a naturally dry bed, or one that is sufficiently drained to make it so, with plenty of rich soil, and in other respects they should be left undisturbed, except to shorten any over-strong shoots, and to nail or tie others, so as to regularly cover the space which they are required to fill. A good washing two or three times in the spring with Gishurst water, allowed to dry on the leaves, is a great assistance in keeping down red spider and green fly. By the sides of shrubbery walks, away from the more dressed part of the garden, where any particular object has to be covered, the Ayrshire and Boursault Roses are generally very much more in keeping with the surroundings than the kinds that produce finely-shaped flowers.

One of the most effective objects imaginable in such a situation is the trunk of a dead tree, with its upper branches partly shortened and covered with Ivy, from amongst which hang pendant, long, untrained shoots of these Roses in flower, with no further tying in than just sufficient to disperse them irregularly over the upper portion of the stump.

Such a combination is easily obtained where the soil is suitable and plenty of manure is dug in; the Roses must also be well supplied with it afterwards, or the Ivy, being a gross feeder, will impoverish the soil to an extent that will prevent them getting sufficient sustenance. Where this combination is attempted, the Ivy should have two or three years' start, otherwise the Roses are such free growers that they will monopolise the whole space. The same arrangement on a wall looks equally well; but, if a successful effect be expected, the Ivy and the Roses must not be left to fight out a war of extermination; on the contrary, whichever is found to be unduly taking the lead must be kept within bounds, and the Roses must be annually manured, for if this be not done, while the Ivy would grow on without any assistance, the Roses would die of starvation. Even under such conditions, the evergreen Roses (R. sempervirens) alone are often much more suitable than those with finer shaped flowers; they are also well adapted for covering arched trellises over walks, or for divisional screens to shut out anything which it is desirable to hide, or for overrunning wooden fences anywhere not overhung with trees, and where the soil is not only in the first instance made sufficiently rich to promote free growth, but is continuously kept in that condition afterwards.

The Noisettes are equally useful for intermixing in the way above recommended; their great advantage is their disposition to flower profusely late in the autumn. The Teas, Gloire de Dijon, and climbing Devoniensis, are unsurpassed for using in this manner; where they have plenty of head-room, the long, unformal branches of the last, with its great clusters of flowers hanging from the points, and the ever-blooming disposition of the former, are not equalled by anything in their way. In the cases of these, again, the principal matter is to see that the roots are well sustained, and to use the knife as little as possible. Where a single object, like a very large-headed drooping standard Rose, is required in such a position as a corner of a lawn, nothing answers the purpose better than the old variety Blairi; where soil and situation suit it, and a strong support is used, it will grow to a very large size. In its case, again, the knife must be sparingly employed, or the result will sure to be a large crop of shoots but few flowers.

One of the Original Cinerarias (C. cruenta).

ANSWERS TO QUERIES.

3682.—**Leaves of Tropæolums Turning Yellow.**—Poverty is probably the cause of the foliage going off in colour. To obtain good results in the culture of these brilliant climbers—that is to say, for winter flowering—the following points must be attended to:—Strike the cutting early in the spring, or even better perhaps, late in the autumn, so as to be ready for spring. Strengthen in rich compost, so that the plants get well established in 10 in. pots by the middle of September, at which time take them to their winter quarters. It must, however, be borne in mind that these plants, although they may be growing in a cool temperature, are called upon to make considerable growth, through the winter months, for it is upon the wood made during that time that the flowers grow in succession. Therefore, not only keep the soil well moistened, but feed it regularly with weak manure water, or give a dressing of concentrated manure. It is surprising what a difference this makes: the effect upon the foliage is magical, and unless the leaves are far gone into the sere and yellow.

they will quickly assume the deep glossy hue of perfect health and vigour.—J. C. B.

3651.—**Plants for Rooms.**—"H. R." wishes to know what plants can be grown where gas is burnt. I have eight rooms in my house fitted with gas, and my window plants are the admiration of all who see them. I grow all sorts of greenhouse plants. If "H. R." wishes to be successful he must see that all his pipes are in good condition, so that there is no escape of unburnt gas. He must have a light ready at the burner when he turns the tap. It s the unburnt gas that injures the plants. If "H. R." will attend to the above he may grow almost any plant he likes.—S. RHODES, *Gee Cross, near Manchester.*

3699.—**Material for Rockwork.**—Get some ordinary coke in pieces to suit your wants, and soak them in some very thin plaster of Paris and water till they are covered, and then let them dry. I dip them in and out of the solution, which must be kept well mixed to prevent the plaster settling at the bottom, and then place them on boards to dry. When you have sufficient quantity, and they are perfectly dry, place them in the position required, and then pour over them some more of the solution a little thicker than the other; they will stick very firmly and have a very nice appearance. Of course, you can alter the colours from white to a light brown by adding a little cement. If you want to make it stand out from the wall without starting at the ground, you can do so, by first cleaning the wall and then pouring some of the first solution on it, and then, after soaking the coke, make some thick plaster, and, taking each piece separately, place sufficient on the back of it to make it stick to the wall; you will be able to leave out a piece here and there, so as to place the soil for ferns, and put in the piece afterwards. I think you will find this the cheapest and most effective way of making a very nice fernery. I shall be glad if you will give the readers of GARDENING the results, as others may wish to try it; and as I have had some valuable hints through the paper, I am only too happy in giving my experience in this small matter.—M. L. A.

—— Roman cement is of a brown colour, and is as good for forming rockeries as Portland cement.—A. B. N.

3655.—**American Cranberry (Oxycoccus macrocarpus).**—I should think this Cranberry would do well in South India. If properly cultivated it is a very beautiful plant, with delicate trailing purple stems and glossy lace-like foliage. Its flowers are splendid amber, and are followed by crimson-tinted berries. These combine to render it a most interesting as well as ornamental plant. It makes a beautiful pot plant, or may be grown in pans of peat, with a little coarse silver sand added, or even sandy loam will do. Place the pots or pans in 1 in. of water, and as soon as the fruit is set, reduce the quantity of water, and when the fruit begins to ripen, keep the plants nearly dry and well exposed to the sun. Thus treated they will be found very beautiful plants, completely hiding the pots or pans. Many people have endeavoured to cultivate them in England, and have failed, for this reason: Some books class them as aquatic, others as Bog Plants, whilst, in reality, they are neither. They like moisture, but not to the extent of aquatics. In their native habit they are a luxurious weed, and produce a great quantity of fruit, and where the best and largest quantity grows the land is only flooded a little sometimes. During dry summer weather they are exposed to a scorching sun, and appear to be dried up. This shows they are not so fond of water as some people think them to be.—J. P.

3665.—**Rabbits Gnawing Trees.**—I use soot, milk, water, and a little coarse fat of any description. The liquid is heated to melt the fat. Mix as paint, and apply with a brush. I have used it for years with good effect. It requires doing once a year.—J. PRIOR.

3590.—**Cutting Back Hydrangeas.**—I have grown Hydrangeas for many years, and some fine ones too, in pots. I planted a good strong plant in front of a lady's house and it grew well, and bloomed and made good strong wood for the next season. I was surprised one day to find it all cut down by the man that had been to clean up the front of the house. I told the owners they would have no bloom next year, and they found it so. I have known others to do the same with a like result. It is quite right to cut away the old wood that bloomed this year, but leave the new wood for next year's blooming.—T. S.

3653.—**Chinese Miniature Plants.**—In reply to a question on this subject which appeared lately in GARDENING, I copy the following extract from "Fortune's Tea Countries of China," and I shall be glad if my exercise affords acceptable information to your readers—GEORGE OSCAR ANDREWS:—"The gardens of the mandarins in the city of Ning-po are very pretty and unique: they contain a choice selection of the ornamental trees and shrubs of China, and generally a considerable number of dwarf trees. Many of the latter are really curious, and afford another example of the patience and ingenuity of this people. Some of the specimens are only a few inches high, and yet seem hoary with age. Not only are they trained to represent old trees in miniature, but some are made to resemble the fashionable pagodas of the country, and others different kinds of animals, amongst which the deer seems to be the favourite. Junipers are generally chosen for the latter purpose, as they can be more readily bent into the desired form; the eyes and tongue are added afterwards, and the representation altogether is really good. . . . . The dwarfed trees of the Chinese and Japanese have been noticed by every author who has written upon these countries, and all have attempted to give some description of the method by which the effect is produced. The process is in reality a very simple one, and is based upon one of the commonest principles of vegetable physiology. We all know that anything which retards in any way the free circulation of the sap, also prevents to a certain extent the formation of wood and leaves. This may be done by grafting, by confining the roots, withholding water, bending the branches, or in a hundred other ways, which all proceed upon the same principle. This principle is perfectly understood by the Chinese, and they make nature subservient to this particular whim of theirs. We are told that the first part of the process is to select the very smallest seeds from the smallest plants, which is not at all unlikely, but I cannot speak to the fact from my own observations. I have, however, often seen the Chinese gardeners selecting suckers and plants for this purpose from the other plants which were growing in their garden. Stunted varieties were generally chosen, particularly if they had the side branches opposite or regular, for much depends upon this; a one-sided dwarf tree is of no value in the eyes of the Chinese. The main stem was then in most cases twisted in a zigzag form, which process checked the flow of the sap, and at the same time encouraged the production of side branches at those parts of the stem where they were most desired. When these suckers had formed roots in the open ground, or kind of nursery where they were planted, they were looked over and the best taken up for potting. The same principles which I have already noticed were still kept in view, the pots used being narrow and shallow, so that they held but a small quantity of soil compared with the wants of the plants, and no more water being given than what was barely sufficient to keep them alive. Whilst the branches were forming, they were tied down and twisted in various ways; the points of the leaders and strong growing ones were generally nipped out, and every means were taken to discourage the production of young shoots which were possessed of any degree of vigour. Nature generally struggles against this treatment for a while, until her powers seem in a great measure exhausted, when she quietly yields to the power of art. The Chinese gardener, however, must be ever on the watch, for should the roots of the plants get through the pots into the ground, or happen to be liberally supplied with moisture, or should the young shoots be allowed to grow in their natural position for a short time, the vigour of the plant which has so long been lost will be restored, and the fairest specimens of Chinese dwarfing destroyed. Sometimes, as in the case of peach and plum trees, which are often dwarfed, the plants are thrown into a flowering state, and then, as they flower freely year after year, they have little inclination to make vigorous growth. The plants generally used in dwarfing are pines, junipers, cypresses, bamboos, peach and plum trees, and a species of small-leaved elm."

3667.—**Violets in Autumn.**—From this time forward one cannot rely upon a constant supply of Violets, unless the plants are guaranteed against extremes of weather by the shelter of a glass roof. In the first place, however, every necessary attention must have been paid them throughout the summer. For although the Violets will give a percentage of bloom with a minimum of care, good flowers and plenty of them cannot be had without some attempt being made at special culture. The great point is to get highly-developed crowns by the beginning of the autumn; and to effect this, young plants must be set out in well-prepared ground early in spring if possible, although good plants may be obtained by planting out anywhere between March and June. These plants must be taken up in October and planted in a frame and covered in frosty weather, or they may be potted and placed in a cool greenhouse.—J. C. B.

3700.—**Cost of Greenhouse.**—Having just built a very small greenhouse, I can give "Wardsley" an idea of expense. Mine is only 10 ft. by 7 ft., but for same, or nearly same price, I might have made it at least a foot wider, as I had materials over. Total cost just under £12, made as follows:—

Brickwork and concrete floor ...	£2	10s.	0d.
Timber	3	5	0
Glass	1	15	0
Carpenter's time	2	10	0
Sundries — paint, putty, locks, hinges, cane run, &c.	2	0	0
	£12	0	0

I used red pine and 21 oz. glass.—T. D.

—— I built a greenhouse from directions given in GARDENING, 21st June, 1879, the design being modified by circumstances. Mine is a lean-to, 7 ft. 6 in. by 6 ft. 4 in., with a wall at back and at one end, and the door at the other end. The height is 8 ft. at back and 5 ft. 6 in. in front, which gives sufficient fall to keep out the water at the laps of the glass. I used stouter material than that suggested, the corner posts being 3 in. square, and the quartering 3 in. by 2¼ in. I bought the sash bars ready made, and also a second-hand door. With these exceptions I did all the work myself. I glazed the roof and door with 21 oz. glass and the sides with 15 oz., and gave the woodwork three coats of paint. Ventilation was provided for by a hinged light in the roof, and another in front. As my plants got drawn this summer, I came to the conclusion that the air did not circulate freely enough, so have lately made two sliding ventilators in front, below the staging, and two at the back, just under the roof. The back wall being a low one, the upper part was filled in with woodwork. To begin with, I only put staging along the front, 2 ft. wide, but have since added more, and also shelving, the cost of which is not included. The time occupied was about 260 hours, spread over two months, and the outlay £4 5s. 7½d. I shall be pleased to give more details if necessary.—A. MILLARD, 282, *Dalston-lane, E.*

3649.—**Culture of Water Melons.**—The Water Melon may be grown in this country much in the same way as are the ordinary kinds, but the plants must get almost unlimited supplies of water at the root when bearing. In Germany the Water Melon is much grown and succeeds well in the open air; but our climate would not be warm enough for it in ordinary summers unaided by glass. The Water Melon likes a free rich soil, such as the turnings out of hotbeds, and if started with a little bottom heat will thrive amazingly in such a compost, which is preferred by the German gardener to any other for this purpose. There is no need for artificial warmth, the superior climate engendered by the glass roof being all that is required to bring it to perfection.—C.

3663.—**Culture of Zinnias.**—The seed should be sown in gentle warmth about the latter end of March in the following manner:—Well drain 4½-in. pots, and fill them to within ½ in. of the rim with fine sweet soil, consisting of one-third loam and two-thirds leaf-mould, adding then a goodly portion of silver sand. Water the soil, and allow superfluous moisture to drain. Sow the seed on a firm surface, and cover thinly with very fine soil, covering with a pane of glass, and shading until the young

plants appear above ground. When large enough to handle prick them off into pans, boxes, or 6-in. pots, and when they have fairly struck root transfer them to a frame, gradually inuring them to a free circulation of air, pulling off the lights in fine weather, so that by the beginning of June they will be in good order to set out in the open ground. To grow the Zinnia well it must enjoy a free root-run in well-stirred soil, requiring at the same time plenty of good nourishment. The piece of ground intended for their reception should now be selected, with a view of affording a careful preparation. If the natural staple is holding, and consequently unduly retentive of moisture during the winter, lay it up now in ridges, selecting a dry, frosty day for the operation. Allow it to remain in this condition until the middle of March, when it may be levelled, and a good coat of manure forked into it. The dung cannot well be too rotten, as it is important that it be equally distributed throughout the soil and everywhere within reach of the roots. This being accomplished, let it lay until planting time arrives, when it should again be well manipulated with a four-tined fork, breaking every lump, and thoroughly incorporating the dung with the soil. This preparation of the soil is absolutely necessary, and forms the keystone of success, and I may add that without it there is but little chance of bringing this fine annual to anything like perfection of growth. Of course, in the case of light soils this amount of labour is not indispensable, but in their case the addition of a little pulverised clay, loam, or good holding soil would do much to ensure complete success, and where the object is to attain exceptional excellence such a slight amount of labour and expense need not be grudged. The Zinnia is a gross feeder, and must be copiously watered when the need for so doing is observed. There is, however, one point in connection with the culture of this plant which the grower must not overlook—the roots must be well mulched with good manure, or failing this a good dressing of some such manurial ingredient as Clay's Fertiliser may be given, mulching with grass or litter of some kind. In conclusion, let me add that a sunny and airy situation should be selected, for the Zinnia is a child of the sun.—C., *Byfleet.*

3643.—**Draining a Garden.**—The most simple plan by which "W. G." can drain his proposed garden is to sink a hole in the form of a well in the most convenient spot, and lay the pipes to it. The well should be a few feet deeper than the lowest point of the drain, and should be walled round with half bricks set dry; if the soil is not a very strong clay the water will gradually filter away. If the water is of any value a pump could be put in at a small cost. Timber or anything will do to cover the well, upon which the soil can again be placed, and the whole is out of sight.—Architect.

3657.—**Striking Rose Cuttings.**—Roses may certainly be propagated at the present time, but they would not be large enough to be of any decorative value until they had the advantage of a season's growth. A shady situation should be chosen, where the sun does not come in spring, and the cuttings should be firmly inserted in fine sandy soil to quite two-thirds of their depth. Only fine, strong wood of the current season's growth should be taken, and each cutting should be cut to three or four eyes.—J. C. B.

3656.—**Propagating Bougainvilleas.**—These are easily propagated from wood of the current season's growth, taking them off when the shoots are in a somewhat succulent condition, that is to say, before the wood has become hard. Insert them in well-drained pots of sandy peat, surfacing with silver sand to prevent damping, and place them in a close frame in a warm house.

3659.—**Wintering and Propagating Leucophyton Browni.**—This plant may be wintered in a temperature of from 40° to 50°, and the young shoots may be taken off early in the year, and struck in warmth, or they will make root in a cool structure freely enough after April.—B.

3661.—**Clematis Heneryi.**—About the latter end of March shorten back the shoots to two-thirds of their length, and apply a good mulch of strong manure. Water copiously in hot weather, and train the young shoots regularly as they grow.—J. C.

3662.—**Tulips for the Open Air.**—Some of the best single kinds are Duc Van Thol and its rose, scarlet, white, yellow, and red varieties, Pottebakker, Rosa Mundi, and Vermilion Brilliant. Doubles—La Candeur, Rex rubrorum, Duc Van Thol, Tournesol (red and yellow), and Gloria Solis.—B.

2758.—**Creepers for Covering Greenhouse Walls.**—I have a frame in a small hothouse over a 4-in. hot-water pipe and a vaporising pan, which has been used for striking cuttings in, but I am now desirous of planting some climbers in it to cover the end wall (eastern aspect and plenty of light. I have the following climbers in pots: Jasminium sambac fl.-pl., Stephanotis, and Hoya carnosa? Which of the three would give most satisfaction as regards profusion and long continuance of bloom?—W. H. J. [The Stephanotis would probably be the best of the three, but the Jasmine would supply a good crop of flowers. You must make a bed of good soil at least 2 ft. deep and 3 ft. square, if you wish for really good results.]

3776.—**Christmas Roses.**—*Norfolk.*—If for pot culture give good drainage, using turfy loam and leaf mould in equal parts. They will, however, do in any good garden mould with sand added. As you have some charcoal break it up to the size of nuts and add a handful to the soil. If for outdoor culture plant in well-drained soil and let them alone. When in bloom cover them with a frame to throw off rains, &c.

3777.—**Privet Hedges.**—*Privet.*—The present is a good time to plant privet. It is propagated both from seed and cuttings—but your best plan would be to buy young plants from a nursery. They are very cheap, and you will gain a couple of years. Well trench and drain the ground, add plenty of rotten manure, and plant in double lines 18 in. apart. The distance from plant to plant in the row must depend upon the size of the plants you get—that is, if you want a hedge as quickly as possible.

3778.—**Pruning Out-door Vines.**—Is the present a good time to prune an out-door vine? And if so, would it be advisable to cut as much old wood out as possible, as it has never done any good?—Kiko. [Prune any time from now to February. Cut out some of the old wood, and remove all unripened shoots, laying in the best ripened wood, which should be slightly shortened.]

3779.—**Plants for Graves.**—What would be the best plant for those metallic crosses which are placed on graves during the winter?—H. N. [Any of the green stonecrops (Sedums) would do, and a few bulbs of snowdrops or crocuses could also be planted with them.]

3780.—**Tuberoses.**—*Norfolk.*—Several answers as to the culture of these have lately appeared in Gardening.

3781.—**Chrysanthemums.**—*J. V. K.*—Cuttings always make better and healthier plants than old stools which are divided.

3782.—**Potatoe Onions.**—*E. C.*—Plant in January or February in rich soil 3 in. deep. When fairly up, earth up a little like potatoes. If you wish to keep them during winter, remove the earth from them, say, in July, and expose the bulbs to the sun as much as possible.

3783.—**Tulips in Pots.**—*W. H. B.*—Keep them in a cool place out of reach of rain. Although they have been potted a month they may not yet have started growth. Turn a pot out and see if there are any roots.

3784.—**Crown Imperial.**—*Amateur.*—The bulbs should be planted 2 in. deep, and if a little manure can be placed round the plant when well up, it will assist them.

3785.—**Clematis Jackmani.**—*Amateur.*—As the plant is a small one, you had better keep it in the greenhouse till April, and then plant it out—in a cool greenhouse we mean, of course.

3786.—**Chrysanthemum Cuttings.**—*C. P.*—Take the cuttings from the young shoots which spring from the base of the plants after flowering.

3787.—**Jasminium grandiflorum.**—*A. A. M.*—Do not re-pot till spring, when the plant has done flowering. If it is pot-bound give it a little manure water occasionally. The best time to prune is after the plant has done flowering. Keep it close to the glass and exposed to the sun during summer in order to ripen the wood.

3788.—**Maurandya Barcleyana and Œnothera Drummondi.**—*L. B. Heulaugh.*—The Maurandya is a perennial under glass, but out of doors is always used as an annual. Œnothera Drummondi is an annual.

3789.—**Salting Asparagus Beds.**—*A. A. M.*—February is the best time for this operation.

3790.—**Ranunculus in Pots.**—*J. R.*—Plant now in 6-in. pots, using light sandy loam, to which has been added a little well-decomposed manure.

3791.—**Hot Water Apparatus.**—*J. R.*—See our advertisement columns.

3792.—**Fuchsias.**—*Scotus.*—Keep the plant rather dry till spring. When it shows signs of growth prune it in if necessary, and when the young growths are well started shake the soil from the roots, and pot the plants in the same sized pot, using fresh mould. Pot into a larger pot as the summer advances.

3793.—**Auticlea Glauca.**—Will this do in a pot plunged in ashes in cold frame, the winter? [Yes.]

3794.—**Oxalis Bowei.**—Would this do in pots in cold frame? When does it flower? [Yes. It flowers in early summer.]

3795.—**Pruning Young Vines.**—*Thos. Clark.*—If the vines are small, cut them down to within two eyes of the soil—pot into larger pot in spring—using good turfy loam. When growing freely apply liquid manure water occasionally, or top dress with manure.

3796.—**Violets.**—*W. A.*—See article in last week's Gardening.

3797.—**Obtaining Plants.**—*Dr. G. W.*—Any of the plants mentioned in Gardening may be obtained through any respectable London nurserymen, some of whom advertise in our columns.

3798.—**Budded Roses.**—In July I budded some Roses, which began growing at once, and have now shoots from 5 to 10 in. long. I am told they will not live over the winter, but as they are very strong I don't see why they should not. It is said budded briar should not be moved for two years. I want to know if it would be safe to move mine next spring.—T. G. [Protect them with a little common dry fern or straw. They may be moved in April with success, but it would be better to to leave them till autumn.]

3799.—**Chrysanthemums after Flowering.**—I have some large flowering Chrysanthemums in Pots, which have thrown up suckers. What must I do with them? Must the old plants be cut down when done blooming, or will they bloom again next year if left? [Cut them down after blooming, and in spring take off some of the young suckers, 3 in. long, and insert them in small pots of sandy soil in a frame, or later on they would strike out of doors. Pot on as required.]

3800.—**Tuberoses Beganis.**—*C. M. M.*—These will do well in a greenhouse from which frost is excluded, or if kept up to 45 or 50 deg. they will do better and flower earlier. Procure some bulbs in spring, and pot them at once in any light rich soil. Keep the soil just moist, and as the pots get full of roots shift into larger pots. They flower better in comparatively small pots than in large ones if supplied with manure water, or a little artificial manure occasionally.

3801.—**Fuchsia splendens.**—Will Fuchsia splendens flower in a window, or does it require heat?—S. G. [It will flower in a window during summer and autumn but in winter it must have more heat than a window generally affords.]

3802.—**Pruning Clematis.**—Should Clematis Jackmannii be cut down now, or in the spring?—S. G. [Now. Mulch with rotten manure afterwards.]

3803.—**Lapageria Rosea.**—I planted a healthy-looking specimen of Lapegeria rosea at the end of September in a rather dark corner of my greenhouse. It still looks well, but does not grow; is the situation the cause?—C. H. [It will grow well in spring, no doubt. Keep the soil moist.]

3804.—**Planting Pear Trees.**—*Lover of a Garden.*—If the weather is open you may plant at once, but if left till March there will be no harm done.

3805.—**Planting Vines.**—*Indicus.*—Young vines raised from cuttings will do as well as those raised from "eyes," if planted properly.

3806.—**Begonia Leaves Falling Off.**—I have three or four plants of the large-leaved Begonias. I keep them in my porch window or the hall. Now the leaves are beginning to droop, and the stems are soft—what is the reason of this? Last year they were in a cool conservatory, and they went in the same manner till all the leaves came off—is this right?—G. H. M. [Unless you have a temperature of 50° to 60° you cannot keep them growing through the winter. Keep them rather dry, and secure from frost, and they will start afresh in spring.]

3807.—**Soot for Vine Border.**—Is soot a good manure for inside vine border?—J. Ingall. [Yes, if mixed with soil as a top dressing.]

3808.—**Indiarubber Plant.**—I have one of these plants 39 in. high, and for a foot from the pot it has no leaves. Can anything be done to make it throw out the leaves? Can they be made bushy plants of? Are they best kept through the winter in the room with fire and gas, or in a room without either?—A. M. K. [Keep the plant in a warm window till spring, then cut it down to within 3 in. of the pot. When it throws out young shoots, remove all but one, the strongest, if you want an upright plant. If you want a bushy one, leave all the shoots that are produced.]

3809.—**Wire Trellises for Creepers.**—*Enquirer.*—Galvanised wire is said to be detrimental to the growth of plants. Your safest way would be to give the wire a couple of coats of paint.

3810.—**Virginian Creeper.**—I have a Virginian Creeper which has not fastened itself to the brick wall of my house, although throwing out feelers with a small ball at termination, therefore has to be nailed up for training. I understood its habit was similar to Ivy, and did not require support. [Veitch's Virginian Creeper (Ampelopsis Veitchi) requires no support, but the ordinary kind does, except in a small state, and against a damp wall.]

3811.—**Cytisus in Window.**—What had I better do for my Cytisus? It was given me in full blossom in the spring. As soon as it had done blooming I turned it out of doors. About a month ago I brought it in, apparently in a healthy condition; now the leaves have nearly all fallen off, and I fear I shall lose it altogether. Should I prune it at all? I have no glass in which to keep it.—M. J. [It does not get air enough After flowering in spring clip in all the shoots with a pair of scissors. Plunge it out of doors, giving it plenty of water. Give it now a little clear soot water.]

3812.—**Deutzia Gracilis.**—My plant of this has looked well up to within the last week, and now all its leaves have turned yellow, dried up, and fallen off. Can you tell me if it is natural to the plant at this time of year? I bought it in the spring in full flower, and it has been the brightest plant of all in my room, which is looking west. I re-potted it after flowering. The roots are rather above the earth now. Ought they to be so? Should it be cut back, and when? Can it be raised from cuttings or slips?—Deutzia. [It is natural for the Deutzia to lose its leaves at this season. It will doubtless flower in spring if the wood is ripe. After flowering cut back all the old wood to within 3 in. of the pot, and young shoots will be produced from the bottom. Keep it in a sunny window, and when the weather gets warm plunge it out of doors in a sunny position, keeping it well supplied with water. Take it indoors again when it has shed its leaves. Do not train the shoots at all. Deutzias can be raised from cuttings of half-ripened wood in August.]

3813.—**Plants Losing their Leaves.**—I have a small greenhouse, heated by hot-water pipes. The leaves of my Rose trees, Fuchsias, Azaleas, &c., go yellow, and drop off. What is the cause?—Delta. [If the Rose trees have been growing all the summer they are sure to lose their leaves now. The Rose is not an evergreen. The same remarks apply to the Fuchsia. Azaleas often lose some leaves at this season. Perhaps they may be dry at the root. Put the pots in a tub of water, and if air bubbles rise from the soil let them soak for half an hour.]

3814.—**Potatoes Sprouting.**—I have saved some early Ash-leaf Potatoes for planting in spring. On examining them lately I find some have sprouts an inch long or more. I should be glad to know if they are still fit for planting, or if this sprouting has injured them as seed Potatoes?—H. H. R. [Rub off the sprouts, and lay the Potatoes in the coolest place possible, excluding frost of course. They must not be kept in a bag or box in a bulk, but be laid out thinly on a board, in a loft or some dry cellar.]

3815.—**Plants in Wall and Screens.**—Will Cotoneaster Symondsii succeed on a wall which gets the early morning sun only? What treatment does it require beyond training? And also kindly advise me as to a creeper suitable to cover open trellis work in the same situation, which I have erected to hide my outhouses from my garden?—A. D. T. [The Cotoneaster only wants to be kept nailed to the wall. Ivy is the best thing you can have for a screen.]

3816.—**Daisies on Lawns.**—*A. D. I.*—The present is an excellent time for digging daisies out of lawns. The ground being soft the roots will come up easily.

Names of Plants.—*W. T.*—Flower of the Edelwiss. —*Sea-weed.*—Euonymus europæus.—*X. L.*—1, Neprodium (species); 2, Blechnum (species); 3, Pellæa hastata; 4, Adiantum assimile; 5, Polystichum aculeatum.—*Dunedin.*—Cannot name your immature fronds.—*A. McC.*—Plumbago Larpentæ.—*G. W. O., Teignmouth.*—Boussingaultia baselloides.—*G. Y.*—1, Begonia Richardsi; 2, Cyrtomium falcatum; 3, Asplenium Trichomanes; 4, Adiantum reniforme; 5, Asplenium maritimum; 6, Adiantum hispidum—*M. M.*—1, Asplenium bulbiferum; 2, Nephrolepis exaltata; 3, Cryptomium falcatum.—*Moss Side.*—Polystichum aculeatum.—*Eittap*—Funkia undulatifolia. Lift it and pot it, and place it in a frame or window for the winter. Plant out in spring.—*R. H.*—1, Tradescantia zebrina; 2, not recognisable.—*C. B. T.*—1. Justicia speciosa; 2. Centrum auranticum; 3, Salvia splendens.—*Ruby*—Cissus discolor, a stove climber.—*E. W. S.*—Cassia corymbosa.—*Rev. A. C.*—Catillac, one of the best of cooking Pears.

QUERIES.

3817.—**Heating Power of Coil.**—How many feet of 4-in. piping can be kept thoroughly heated by a coil made of 14 ft. of piping, 1 in. bore? The coil is five complete rings.—K. G. W., *Hull.*

3818.—**Winter Treatment of Amaryllis and Agapanthus.**—What is the proper winter treatment of the Scarboro' Lily, Agapanthus, and Amaryllis, as regards watering, re-potting, &c.?—Alpha.

3819.—**Ants in Greenhouses.**—My greenhouses being infested with ants, I should be glad of some information how to eradicate them. I have tried several remedies, but all have failed. A correspondent, p. 418, recommends arsenic mixed with honey as a speedy cure for them. I have tried it, but find they will not touch it.—W. H.

3820.—**Raspberries on North Wall.**—Would Raspberries thrive and fruit well if planted against a north wall, on a border sloping downwards from the wall?—Fidus Achates.

3821.—**Myrtles from Seed.**—I have a Myrtle that has seeded this year. Could any of your readers inform me in what kind of soil I should sow the seeds, and at what time of year?—Ignorance.

3822.—**Plants from Stiff Clay Soil.**—What plants will cover a border, in front of evergreens, on a clay soil, most quickly?—E. S.

3823.—**Glazing without Putty.**—Can any reader inform me, from experience, whether any system of patent glazing without putty answers for a vinery or greenhouse? Are they free from drips, and do they keep the heat in as well as a house glazed with putty?—W.

3824.—**Renovating Beds of Lily of the Valley.**—I have a bed of Lily of the Valley which has very much degenerated. Can any reader suggest a remedy?—Monk.

3825.—**Removing Glass from Greenhouses.**—Can any reader inform me if there is any simpler plan of unglazing glass than the old one of cutting away the hard putty; also, is there any sort of putty, which, although setting hard, could be softened in any way, after some years, so as to allow the unglazing of the glass?—Putty.

3826.—**Vines and Rats.**—My Vines have been getting dreadfully barren—one was eaten off close to soil—and I fear the roots of all are being eaten away, as holes are seen where the rats seem to burrow in the "drainage" of border. They laugh at all traps, and also all bottles and other stuff sold for their destruction. Arsenic mixed with meal used to kill all in Devon, where one could get it by signing one's name, but, in London, druggists seem to fancy that all who apply for such, for rats, are would-be-homicides! Can any one tell me how to exterminate these pests?—C. Mabor.

3827.—**Lavender Culture,**—Information respecting the growth of this and probable expense per acre, &c., will be thankfully received.—South Devon.

3828.—**Preserving Skins of Birds.**—Can any reader inform me the best way of preserving bird skins, to keep the moth from them?—W. W.

3829—**Climbers for Trellis.**—I have a wire trellis arch over a stream about 15 ft. wide, which I wish covered with creepers—what Roses would be best. Also, will Clematis and Honeysuckle do well? It is a damp place, and on one side the roots will be nearly in the water. Should be much obliged for any suggestions.—A. Wilder.

3830.—**Garden Polyanthus.**—In Gardening, Nov. 20, some notice of the old florists' Polyanthus is given, and "A. D." mentions, as good ones, Buck's Geo. IV., Lancer, Exile, Cheshire Favourite, President, and Early Lincoln. He also says that "they should be obtained from some bonâ-fide grower, as there are not a few wretched sorts in commerce under these names." The prices, he tells us, range from 2s. 6d. to 3s. 6d. In a book called "The Flower Garden," published in 1840, Buck's Geo. IV. is priced 1s., while another of his raising, the Marquis of Anglesea, is marked 20s. Geo. IV. is now, I believe, much higher in price, as also is Lancer, which was then 1s. It is difficult, however, to obtain these old fashioned but charming plants, and it would be a boon if your correspondent would help one, who would like to grow a few of them, to some knowledge of the retreats where they lie hid. About seventy named sorts are mentioned in the above-named book, and it is an interesting question—What has become of them?—H. S.

3831.—**Holly for Walking Sticks.**—Will any one inform me the proper time for cutting holly for this purpose, and how to stain the sticks?—Montgomery G.

3832.—**To Grow Mercury.**—Will anyone give me a few directions on the culture of Mercury? I have a bed which has grown too thickly to be of any use.—Montgomery G.

3833.—**Flower for Winter and Spring.**—What could I put in a greenhouse now for decoration at Christmas and early spring? I shall have a fire on all frosty nights, which will keep the house at a moderate degree of temperature. What seeds could be sown for early spring bedding?

3834.—**Planting Roses.**—When is the best time to plant bush roses, and which are the best kinds; also the best time for planting a climbing rose in the greenhouse?—Lover of a Garden.

3835.—**Cineraria Leaves Curling.**—Will some one tell me the reason of Cineraria leaves curling? They are very free from green fly. Would too strong manure water cause it? Thermometer not been below 34.—Anxious.

3836.—**Blanching Celery Indoors.**—At the commencement of November I dug up a couple of roots of green Celery intended for soup, but, by some means, after being placed in a jug of water, they were overlooked for three weeks, at the end of which time it was discovered that the Celery had sprouted, and sent out fresh leaves, but not only was this the case, but the stalks were found to be blanched and crisp. At the same time, though unusually succulent, the flavour was excellent. I shall be glad to know if any readers have made a similar experiment, and with a like success.—B. J. H.

3837.—**Passion Flower Failing in Greenhouse.**—I have a Passiflore cerulea, procured from a nursery this year. Its growth has been good, but no flowers. Can anyone inform me the reason? I have grown it in a 9-in. pot, and treated as directed in Gardening.—G. R.

3838.—**Making a Flower Stand.**—I have an old oak chest, 1¼ yards in length, ¼ yard across, ¾ yard deep, standing under a window facing west, which I wish to convert into a pretty flower stand. Will some one give me an idea how to go about it, and suggest something for training downwards, as well as to fill in the top? It is in a good situation, having plenty of light and afternoon sun.—W. X.

3839.—**Plants for Room.**—I have a small room, without a fire, in which little or no gas is burned, with a N.E. exposure, in which I intend having an oil stove. Will some one say what flowering plants I could cultivate in it—now and in summer?—Dunedin.

3840.—**Wintering Ferns.**—Would some kind reader give me some information as to how I am to keep some Ferns till next year? I have had some Maiden-hair Ferns, Crispis crispendum, and several other Ferns growing in the open room, but now that winter is coming on they are beginning to die down, and I am afraid of losing them altogether. Also some information as to what kind of soil will be best for keeping them in when under cover, as I am having a glass case made for them. Will they come on all right again if I put them into the case, or had I better wait till next spring?—W. J. H.

3841.—**Tropæolum Speciosum.**—I find great difficulty in transplanting Tropæolum speciosum in spring. Would someone kindly state the most satisfactory mode?—A. R. F.

3842.—**Cropping a Kitchen Garden.**—I have just taken a plot of ground for a garden, 78 ft. × 18 ft., and have already turned it up into rough ridges. The soil is a very fair brown loam, and had lime thrown on it about two years ago, when a chapel was built close to it. It is one mile from the sea, on the north-east coast, but sheltered on the east by a hill and a ten-feet wall; the same on the south, and a church on the west, and on the north a terrace of houses about fifty yards away. I want to make a kitchen garden only. What can I plant, and how soon? Also, can I forward any of the seeds, as I have got several boxes with plate and sheet-glass tops, and the bottoms taken out, averaging 24 in. × 18 in., and 15 in. high? What kitchen garden produce is likely to succeed here?—Finem Respice, *South Shields.*

3843.—**Converting Old Lawn into Vegetable Plot.**—Last September I dug up an old lawn of some twenty years' standing, with the intention of converting it into a vegetable bed; but I am at a loss to know how to bring the rank yellow clay into anything like working order. What is the best and quickest way of loosening the clay? Would burnt earth answer the purpose, or should it be thoroughly-rotten manured? It wants something to make it crumble. It is not needed for use until the spring.—W. C. C.

3844.—**The Artillery Plant (Pilea muscosa).**—Will someone tell me the treatment of this plant—the proper soil, watering, temperature, &c.?—S. L.

POULTRY.

Fowls in small Spaces.—I have kept thirty Plymouth Rock Fowls through the summer until the last few weeks. I have reduced them down to eighteen in a house 6 ft. by 3 ft., 5 ft. high, and have not had one death or sign of illness. I clean them out every morning, and sprinkle lime over the house, especially damp parts, and although so crowded I have never seen anything like an insect either in the house or birds. I may add that I make a large hole in the garden, in which I sift the cinders every morning, and they enjoy a bath in the warm ashes, which I have no doubt prevents insects.—R. S.

Food for Geese and Ducks.—In Gardening, Nov. 16, "North Yorkshire" says that he can rear Geese 12 lb. weight in eight weeks, at a cost of 2d. per week, and Ducks at 1½d. Would he kindly say what food he gives to bring on the Geese and Ducks so cheap and quickly? I am anxious to try poultry farming, but don't know what is the best food to use, and should be glad of a hint on the subject.—East Cornwall.

Lameness in Fowls.—Can any reader of Gardening advise me under the following circumstances?—I have a Spanish Pullet, which for some weeks past has been limping about, but she is now quite lame. A careful examination of foot, leg, and thigh, on several occasions, has failed to discover any sore or wound. She feeds well, but is, notwithstanding, a mere bag of bones. I have been recommended to kill her, but should prefer to try some remedy first, if the complaint is one that is amenable to treatment. I may add that my other Pullets (four) seem the picture of health and activity, and to all appearance will shortly begin to lay.—One in a Fix.

Fowls Plucking their Feathers.—Would anyone kindly let me know how to prevent Fowls from plucking the feathers off one another? They make one bleed, and then they all go after it, and we are obliged to take it away. They are penned up.—Subscriber.

HOME PETS.

Silver Grey Rabbits.—Will some reader kindly inform me the average price or value of a buck, doe, and young Rabbits of this breed at six weeks old respectively?—C. H.

Goldfinches.—"W. H. B." probably procured his Goldfinches a little too early in the year. They were too young and not sufficiently strong to withstand cage treatment. I have had some myself which were lost in the same way. Better try older birds next time.—G. F. W.

Different Birds in one Cage.—All the birds that "J. B." alludes to will do in one cage, but the difficulty is in providing proper seed for them all. Mix hemp, rape, canary, linseed, millet, and groats together. If put separate, perhaps the Canaries will eat too much of hemp and linseed, which will not do for them.—G. F.W.

Canary not Singing.—The question which "F. C." asks is the question of many people. The birds have probably been allowed to have a good deal of hemp seed. They will get fat and plump on this seed, but it makes them lazy, and they will not sing. "F. C." had better omit hemp from his usual mixture for a time, and give instead maw seed (a little) and mountain bread.—G. F. W.

Canaries with Long Nails.—I have a Canary which has a long nail on each foot, which causes the bird to stumble. Would some experienced bird-fancier state whether the nail could be cut without injuring the bird?—Amateur.

Curing Rabbit Skins.—Can any reader inform me how to preserve the skins of tame Rabbits without injuring the fur, and so as to prevent smell or decay?—Forester.

Teaching Parrots to Talk.—The grey birds will be most teachable—constancy in teaching, in the same tone of voice, is the secret. A handkerchief thrown over the cage during each lesson keeps his attention fixed. Try the grey Polly first.

Unhealthy Canaries.—Canaries suffering from asthma, which no doubt "W. P." and "C. W. W.'s" are, should have light food, such as sponge cake, bread soaked in milk, chopped egg, as well as their usual food of rape and canary seed (no hemp). Keep out of damp, draughts, and gas. If much oppressed give the following:—Ethereal tincture of lobelia, ten drops; compound tincture of camphor, one drachm; syrup of ginger, three drachms; cinnamon water, one ounce. Put two teaspoonfuls of this mixture to two ounces of water; give it to the birds to drink in the place of their ordinary drinking water; continue till the most distressing symptoms have left, then reduce the dose to one-half, which leave off when well.—P.

Singing Mice.—Can any of our readers inform me where could I procure these pets? I have often heard of them, but never saw any. What sort of singing do they resemble? What is their size and colour?—A. M. R.

Cornish Method of Producing Clotted Cream.—Milk in winter should stand in the pans, after straining, in a cool place full twenty-four hours before placing on a slow *clear* fire, or better still, a hot plate on a close range or kitchener, and must be allowed to remain until a ring forms itself on the cream of the size of the *bottom* of the pan, which will always show itself when sufficiently scalded. Care should be taken to prevent it boiling, or the cream will be spoiled. When ready take it off steadily and carry to a cool place; the slabs or shelves on which it is laid should be slate or marble. The cream can be taken off the following morning or left for twenty-four hours. In summer it must be scalded twelve hours after milking, and cream taken twelve hours after scalding. I consider it a bad practice to disturb the cream to look for air bubbles rising on the milk beneath, as given by "G. N. B." last week. The formation of the ring is a true indicator.—Experience.

GARDENING
ILLUSTRATED.

VOL. II.—No. 92. *SATURDAY, DECEMBER* 11, 1880. PRICE ONE PENNY.
REGISTERED FOR TRANSMISSION ABROAD.

DRACÆNAS.

THESE are very common inmates of plant-stoves and greenhouses, some of the species requiring the former, others the latter kind of protection. They are all exceedingly attractive, some of them having most beautiful and conspicuous foliage, whilst their habit is such as to render them very useful for all kinds of decoration. They are easily grown and difficult to kill, although to bring them down to a ragged unsightly condition (as may often be seen in plants with their bottom leaves half decayed and the younger ones blemished at their points) is a very simple matter. Small plants are generally the most needed and are serviceable for room and vase embellishment; and, when used for this purpose, for which they are more and more in demand, they remain for a long time in perfection. Large plants are required frequently for staircase, balcony, and entrance-hall ornamentation. The drooping foliage of some, and the upright leaves of others, and the tropical appearance of all, render them splendid objects when used in such places. Some of the most tender species are sometimes placed in the sub-tropical bed or garden during the summer. This treatment can only be given them in southern counties. Dracænas should be very extensively cultivated on account of the extreme easiness with which they may be propagated; a single stem 3 ft. in height will produce three dozen young plants. When any plant becomes uselessly tall or bare of foliage, it should be cut into pieces about 1 in. long. These may either be put into a bed of soil on a hotbed, or be placed thickly in pans filled with a mixture of peat and silver sand. After watering the pans should be plunged in a bottom-heat of 85° or 90°; here they should not be allowed to suffer from want of water, although being plunged, the quantity required will not be great. The young plants sometimes come up irregularly, but none should be taken from the pan until they are all fit for removal. As soon as this is the case, the whole panful may be carefully turned out, and potted singly into 3-in. pots, without damaging the young roots. They should again be plunged in the same place, and kept there until they show signs of growing; after that they may be removed, and placed on a shelf or some other hard bottom in the plant stove or propagating frame, where growth should be encouraged until they are ready to be shifted into larger pots. Hitherto, they will have been potted in the same material as that in which they were rooted, but at this shift, peat, sand, loam charcoal, and a little decayed Mushroom dung may be introduced with advantage. The mixture must not be too fine, but sufficiently so to admit of a certain amount of all the in-

ONE OF THE MODERN DRACÆNAS (D. ALBO-MARGINATA).

gredients being put into a 5-in. pot. This size will grow well-furnished plants until they are 18 in. or 2 ft. high; when, if they are wanted of larger dimensions, they must be shifted on, the same mixture being used as that just referred to. After being shifted from the small pots, they generally do not require more root-room for one season than is afforded them in the 5-in. pot, so that the following spring is a suitable time for potting on large plants. Very fine plants can be grown in 5-in. pots, which is the most convenient size for decorative work. Another means of propagating is found in the root. Large plants form a number of thick leading roots at the base of the stem; at the end of each of these there is an eye. If an old stem be cut up these eyes should be cut off, and put in together with the other eyes. In shifting well-grown plants into larger pots, these eyes may be taken off during the operation without injuring or checking the progress of the plant. In this way a fresh stock may be raised without even cutting down a large plant; and when only a few are required, these root-growths are preferable to any other. Sometimes the tops are put in as cuttings, but these seldom make such good or handsome plants as those from eyes. When propagated and in growing order, their daily requirements are few. A slight shading is necessary at all times during strong sunshine. They are particularly sensitive to dryness at the root, which often entails the loss of the lower leaves; and the points of the tender young foliage are sometimes allowed to wither through the same cause. Dracænas are sometimes grown in pans about 10 in. in diameter and 2 in. deep with good effect. The young plants are placed in these pans when quite small, so that the root is easily covered with soil. When this is done, some of the finest kinds of the Selaginellas and the pretty creeping Panicum variegatum are planted on the surface of the pans, a method which produces a remarkably pleasing effect, as the creepers form a cushion of green and white underneath the drooping high-coloured leaves of the Dracæna. As regards varieties, there are now some in commerce which quite eclipse all the old kinds, that is, as far as boldness of character and brilliancy of the leaves are concerned. Mr. Bause has, during the last five years, raised in Mr. Wills' nursery at Anerley (now the General Horticultural Company) many noble kinds of Dracænas, from which we select the following as being among the best:—

Dracæna albo-marginata, which we now figure, is a strong-growing variety of stocky growth, with large, recurved leaves, measuring 4 in. across, of a bright green colour, with a clear, narrow, margin of white.

D. anerleyensis is one of the bold-habited free-growing series, with oblong, spreading leaves, the younger ones more erect. They are of a dark bronzy green, with a very bold and broad variegation, marginal and sectional, of deep rosy-red, which in all the younger stages has a decided purplish tint. This pale purplish hue flushing the greenish-white of the youngest central growth, gives it a very distinct and pleasing aspect, and renders it an effective plant.

D. Barroni is a striking variety. The leaves are oblong, 5½ in. broad, spreading or half-drooping, of a dark bronzy-green, with a broad and irregular edging of mottled magenta on the younger leaves, the edges of the older leaves being of a deep magenta colour. The edges of the leaf-stalks are of a rosy-pink; the young leaves come first of a creamy blush, with a rosy tint on the under-surface, and in some cases they take on this roseate hue on the upper side. It is a fine and noble-habited variety of great beauty.

D. Bausei is a highly-coloured and most effective variety; the growth is free and stocky, the recurved oblong leaves, which are about 4 in. in width, closely overlying each other; the surface is of a dark bronzy hue, the margin being crimson, narrow in the lower leaves, becoming broader and more developed in the upper ones, the youngest and uppermost being broadly and brilliantly edged with deep rose, and the margins of the leaf-stalks also richly coloured.

D. Elizabethæ is a very handsome variety and remarkably distinct, not only on account of its variegation, but also of the tendency of its leaves to curl under volutely. It is of dense habit with broad, strongly recurved leaves, measuring 5 in. across, of a dark green colour, with a dark midrib, and a narrow edge of bright rosy-crimson on the older leaves, and with a broad-margined variegation of deep pink and creamy white on the younger leaves, the leaf-stalks being conspicuously coloured of a rosy tint.

D. Ernesti.—A well-marked variety, of erect slender habit; the leaves are lance-shaped, 1½ in. wide, tapered to a point, drooping or recurved, of a bronzy-green colour, with dark crimson edge; on the young leaves the parts are coloured rosy-pink and creamy-white. It is one of the very best of the narrow-leaved, yet compact kinds, and will become a general favourite for table decoration, being of a very hardy constitution.

D. Gladstonei.—A variety of bold habit, with densely set drooping or recurved oblong leaves 4 in. broad, of a very dark bronze colour, the younger leaves breaking into a deep crimson suffused with salmony-rose. It will form a valuable plant for decorative purposes, being of a very hardy constitution, of very free and erect growth, and calculated to form a tall specimen.

D. ignea.—A very striking variety, of medium stature and development, belonging to the flame-red series. The leaves are arching, with erect, rosy-edged foot-stalk, the blades green, broadly edged with a band ¼ in. wide, of flame colour or deep salmony-red, breaking out into streaks and sectional markings in free young growth. It is extremely effective.

D. Leopoldi.—A fine variety, in which the leaves are of an oblong-elliptic form, drooping or recurved, measuring about 5 in. across, the ground colour a bronzy-green, with bright rosy-crimson edge, the younger parts of a lovely pink, flushed in places with a pale tint of coppery-bronze, which gives it a very distinct appearance. The leaf-stalks are also prettily edged with rose.

D. majestica is a free-growing form, with fine and effective variegation. The leaves are oblong, 4 in. broad, with erect foot-stalks 4 in. to 5 in. long, green, edged with salmony-rose, the leaf-blades being very distinctly bordered with ¼-in. wide band of bright flame-red, most developed at the base. This is one of the very finest of the whole series, and well deserves the name assigned to it.

D. Mrs. Bause.—A very pretty dense-habited variety of moderate growth and wonderful colouring, having the leaves drooping or recurved, 9 in. to 12 in. in length, and nearly 2 in. broad, of a bronzy-green colour, margined and striped with deep crimson, the younger and upper leaves often becoming wholly of a deep rosy-crimson. A very richly-coloured and effective kind, rarely exceeding 18 in. in height.

D. Mrs. Wills.—One of the finest and handsomest of all the varieties with white variegation. The plant is of dwarfish, stocky habit of growth, the leaves about 3½ in. wide, erect spreading, the ground colour bright green, the older leaves being striped with white on the green ground colour, and the younger ones very freely variegated with, and in some cases almost wholly coloured, white.

D. Tellingi is a bold-habited sort. The leaves are oblong, 6 in. broad, drooping or recurved, of a bronzy-green, with an edging of bright rosy-pink, which in the older leaves deepen into crimson, the leaf-stalks being also nicely coloured at the edge. It has the boldest and broadest leaves in the whole series, and they are, moreover, remarkably stout in texture.

D. terminalis alba.—This is a most important acquisition, having quite the habit and character of the well-known favourite, D. terminalis, but with white variegation. The ground colour is bright green, with bold pure white variegation, the upper leaves being white, with here and there a bar or band of green; in some cases large sectional patches are coloured white, while the rather elongated leaf-stalks are also edged with white. It will be a useful variety for general purposes as well as table decoration and for market, being of very free growth and remarkably hardy constitution.

D. regalis.—A bold-habited free-growing vigorous variety, having densely set oblong recurved leaves, of a deep bronzy-green, margined unequally with rosy red, and having the leaf-stalks also similarly edged; the younger central growths are broadly edged with cream colour flushed with pale rose. It forms a fine massive and truly regal plant, and from its free growth and its ample foliage is very effective.

D. salmonea.—A tall, slender-growing, and very distinct variety, with the long-stalked, sparsely set, erect, channelled leaves, of a narrow lanceolate form, tapered to the point, 3½ in. broad, the ground colour deep green, with the edges distinctly marked with salmony-pink, which colour is extended down, and very conspicuous on the edge of the petiole. The salmony-tinted, almost flame-coloured leaves, which are paler in the younger ones, are a very distinct feature, and give the plant a very bright-looking aspect.

D. Sidneyi.—A striking variety of the narrow-leaved series. The leaves are long-stalked, erectly spreading, 1 ft. long, and about 1½ in. wide, dark green, with a deep purple mid-rib, and dark rosy-crimson edge, the younger leaves being wholly of a rosy-crimson colour. The petioles are finely coloured with the same rosy-crimson hue. It is a valuable variety for table decoration, on account of its very early colouring and graceful habit.

D. superba.—This hybrid is one of the slender-foliaged varieties, and from its graceful habit will be most useful for table decoration. The leaves are pendulous, arching, from 12 in. to 18 in. long, by 1½ in. broad, linear-lanceolate, dark bronzy-green, margined and striped with bright crimson; the young leaves are rosy-crimson.

Among the older kinds the following are most worthy of culture:—

D. terminalis is one of the oldest, best known, and most beautiful. The leaves grow from 1 ft. to 2 ft. in length, and 4 in. and 5 in. in width; they are of a dark green colour, richly and profusely shaded with brilliant scarlet; the young leaves and the entire upper part of the plant are sometimes wholly scarlet.

D. Chelsoni makes a fine plant. The leaves are very large; the ground colour is a bronze-green edged with crimson.

D. Cooperi somewhat resembles the first described, but is, if possible, more beautiful in colour and more graceful in habit. It is moderately hardy, and does fairly in the greenhouse during the summer months.

D. Guilfoylei.—A magnificent species, with long narrow leaves beautifully variegated and striped with bright rosy-pink, white, green, and red; the leaf-stalk is also variegated. Being a native of the South Sea Islands, it is somewhat tender, but, like the rest, easily grown.

D. gracilis is an elegant little plant; the leaves are only about 1 in. in breadth, 12 in. in length, and incline nearer to the horizontal line than those of other kinds. The main colour is bright green, margined with purple.

D. Dennisoni is another elegant species, of the deep bronze type; leaves from 12 in. to 15 in. long; habit compact; other characters good.

D. regina is different from any of the preceding, and a fine variety; leaves erect, centre green, edged with creamy white; sometimes the upper half is quite white, which gives a speckled appearance to any collection with which these plants may be intermixed.

D. umbraculifera is quite different from

any of the above; it grows several feet high; the leaves are generally about 3 ft. long and 1 in. broad, and of a rich, glossy green colour; at the top they stand straight out, but the older ones at the bottom droop. The plant, when large, forms a conspicuous object anywhere; it grows rapidly.

D. magnifica.—Leaves about 8 in. in width, and as much again in length. When young the leaves are pink in colour; when old they are of a purple-bronze shade.

D. Draco, D. australis, and D. atro-sanguinea are nearly hardy, and useful for conservatory decoration.

Building a Greenhouse.—Having been a subscriber to GARDENING since its commencement, I have read with much interest, from time to time, the communications of those who have essayed building a greenhouse, but I have not found any who have tried to make a span-roofed one. It sometimes happens that, from situation, or from sanitary considerations, a lean-to house is unsuitable, and for those like myself who find themselves in this fix, perhaps it may be acceptable if I give my experience in the erection of a small span-roofed house. Part of the party-wall which separates my house from my neighbours' is 8 ft. high, and this I made use of for one end of my house, the two sides and door end being on brick walls 2½ ft. high (the inside having to be dug out), the floor of the house being thus on a level with the 5 ft. way separating the one side from the kitchen window. Of course, on the other side, the top of the wall is on a level with the garden, to which, at the door end, a few steps lead up, and by having it thus half sunk I find I can keep up a fair temperature with little artificial heat. When the thermometer lately registered outside from 6° to 8° below freezing, the heat inside, from an oil stove, was 18° above that, even with the ventilator at top slightly open. The size of the house is 11 ft. long, 7 ft. broad, and 8 ft. high in the centre, and 5½ ft. at the eaves, the cost of material being as follows:—Wood, for wall plates, uprights, rafters, 1½ ft. staging all round, shelving at wall end, and wood flooring, £1 11s. 8d.; 450 bricks, and hauling, £1 2s. 6d.; digging out earth, and hauling, 9s. 0d.; paint, at 4½d. per lb., two coats, 7s. 6d.; stove and brackets, 10s. 0d.; glass, £2 2s. 5d.; putty, 4s. 5d.; zinc for gutters, 6s. 2d.; total, £6 13s. 8d. I have not entered into particulars with above items, as it would take up too much space, but I shall be happy to give it to any one who may be contemplating trying his handiwork on a similar structure. I heat with an oil stove, and having two top ventilators, I leave one open a little night and day, a thermometer inside guiding me as to the judiciousness of this. The exposure is south-east.—G. S. C.

Violets in Winter.—The earliest single Violet with which I am acquainted, and at the same time the finest and most valuable, is Lee's Victoria Regina, a variety that ought to be grown in every garden, and would be, did people fully understand what a grand Violet it is. The earliest and best kind, undoubtedly, is Marie Louise; it is a greatly improved Neapolitan, earlier, hardier, and has flowers of a rather deeper hue of colour. Both of these kinds will furnish an abundance of flowers during open weather through the winter, but it would be well to lift a number of strong plants and put them into a frame, keeping them close to the glass. Thus treated, and with a slight amount of protection in bad weather, flowers could always be had. If plants be lifted for this purpose now the side-shoots and runners should be taken off them, and they should be pricked out thickly in a bed for the winter. By the middle of April these will be all well rooted, and can be re-planted in beds from 9 in. to 12 in. apart, where they will develop into strong blooming plants by the ensuing winter. There are few hardy plants more easily cultivated than the Violet, and few better repay any extra care that may be bestowed upon them. On the other hand, however, if there be out-of-the-way spots where other useful plants cannot be got to grow, it is very probable that Violets will do fairly well, always furnishing a good covering of leaves, and in due season a fair sprinkling of flowers, although not so fine as those produced by younger plants.—D.

FRUIT.

Good Bearing Apples.—Although this part of Hampshire is not a noted one for Apple culture, yet a great many sorts are grown hereabouts which are good croppers. Amongst dessert kinds I find the following to be about the best, viz., Summer Golden Pippin, King of the Pippins, Cox's Orange Pippin, Gooseberry Pippin, Golden Winter Pearmain, and Red Russet. The best kitchen sorts are Mank's Codlin, Winter Codlin, Blenheim Orange, Ecklinville, Hawthornden, Northern Greening, Profit, and one or two local sorts for which I cannot find names.—W., *Fawley*.

Coe's Golden Drop and Italian Prune Plums.—The best autumn Plum in cultivation is Coe's Golden Drop, which will keep good for weeks if gathered before it is over-ripe. We

Italian Prune Plum.

have had good fruit of it for dessert in December by keeping it in a dry room. It grows and fruits freely on both east and north walls. We have had no experience of it as a standard, but the tree has a good constitution, and would, no doubt, do well in that form. The Italian Prune, or Quetsche d'Italie, is also another very excellent dessert Plum, having somewhat the same characteristics as the preceding, with the excep-

Coe's Golden Drop Plum.

tion of colour, which is a deep purple. The flesh is yellow and very rich and full flavoured, rendering it a most desirable variety to cultivate. —W. W.

Easy Way of Warming a Frame.—I have a double frame-light, constructed after the ordinary principle, except that one end is left entirely open, but the front and back of the frame is secured by two bars of wood about 3 in. wide and ¾ in. thick, let flush into the perpendicular pieces "to which the back and front are fastened," and secured by four bolts and nuts—thus making the frame perfectly strong. The open end of this frame is placed against the brickwork of a kitchen chimney, and kept in its place by four staples driven into the wall, and the frame secured to them by a nail or screw at the head of the staple. This frame-light is of the following dimensions:—Height at the back, 34 in.; front, 8 in.; and the lights are 6 ft. long by 3 ft. wide. Now, the reason which induced me to have a frame made and placed at the back of my kitchen chimney is told in few words. Having noticed repeatedly, after a heavy rain, which beat at this end of my house, that the portion of brickwork constituting the kitchen chimney appeared to be much drier than any other, consequently I put my hand upon it, and to my surprise found it quite warm. This was about 6 ft. from the base, and lowering my hand I found the heat increase, until I came to exactly the back of the kitchen range, and here the bricks were quite hot. I have had this frame in use for several years, and have never lost any plants or cuttings from frost. This end of my house forms a portion, or one side of an enclosed yard of good size. The aspect of my

frame is due south, but that of the end of my house is due east. I have no houses near or large trees to keep off the influence of the sun, so that the heat in the frame is very often a little too much, and requires ventilating, especially in the spring. Few houses, perhaps, afford the great convenience in this respect that mine does; but where such does exist, I would suggest, instead of a frame-light, that a greenhouse be erected, for it could be easily heated by hot water, simply by inserting two pipes into the boiler of the kitchen range, and then you have it complete. As regards the frame-light, it should be so raised as to receive the greatest amount of heat from the brickwork of the chimney.—A Subscriber.

The Cloche Protector.—Here is a sketch of a simple and inexpensive protection for plants, either under *cloches*, as represented, or grown in the ordinary way. This cover is made of bands of straw, interwoven with cord, so as to make a firm mat, 2 or 3 ft. in width, and of any length that may be found necessary. At each end of a protector of this kind is affixed a wooden jamb or margin, hinged on to a peg, which is sunk into the ground, as shown in our illustration. It will be at once seen that the protector can, by this simple arrangement, be set at any angle, and, from what we know of it, we can recommend it as an efficient protector from both cold and sun, and a useful aid in the raising of seeds, cuttings, and tender crops.—W.

Effect of Lime Water on Plants.—Why "Tried One" should have experienced such disastrous results from the use of lime water is a mystery to me. I have used it to all kinds of tender-rooted plants, such as quickly feel even a slight overdose of clear water, and never in a single instance with ill effects; on the contrary, with it the foliage quickly assumes a darker tint, and the greatest change is observable in the texture of the leaves and the flowers, which acquire, when the applications are frequently given, unwonted substance. I have always considered lime water to be one of the safest manurial agents, for it is a rather curious fact that so much water will only hold so much lime in solution, so that no matter how much lime be put in a vessel the water will remain of one unvarying strength. My plan is to put enough lime in a tub to ensure its growing the desired strength, when the tub is several times refilled, but I take the greatest care to use it perfectly clear. If "Tried One" has not taken this precaution, and has used the liquid at all thick, the affair is at once explained, for the moisture thus used would not only choke the pores of the soil, but would also scald the principal feeding fibres.—J. Cornhill, *Byfleet*.

Plant Protectors.

VEGETABLES.

Mushrooms in Winter and Spring.—Although mushrooms form a valuable addition to our list of kitchen garden productions at all seasons, they are exceptionally welcome from October to May. I doubt, however, if there be not more failures in their culture than in that of any other esculent grown—and these chiefly from kindness rather than from lack of attention. The routine which we adopt with general success is very simple, and varies little from that generally followed, viz.:—Sufficient fresh stable manure is shaken out from the longest litter to make one good large bed. It is carted into a heap, and about one load of fresh turfy soil is added to four of manure; this is turned over two or three times, at intervals of a couple of days, to prevent violent heating, and if very dry and likely to become mouldy, sufficient water is added to ensure a general sweet temperature throughout the heap. When fit for making into a bed it should be about 85° or 90°, and neither wet nor dry, but moist. We make up our beds in dark sheds or cellars, where a close, warm atmosphere, not easily affected by external temperature, is maintained at an average of 60°. Fire heat should be applied with caution, as it is too drying, and when fresh successional beds are in course of formation, the genial warmth given off by them is far more congenial than fire heat. We make the beds from 15 in. to 10 in. deep, and tread them firmly, in order that the heat may be gentle and lasting; after a few days the spawn is inserted in pieces about the size of a hen's egg, 1 ft. apart, just covering it with the manure. Upon the quality of the spawn success depends: if good and fresh, there will be abundance of Mushrooms; if bad, there will be few or none, however well the bed may be made or treated; therefore the spawn should be obtained from a trustworthy source. Use it fresh, or store it in some perfectly dry, airy position until it is required. The beds should be earthed with good fresh loam, beaten down as solid as a spade can make it, and in a month or six weeks the Mushrooms will begin to make their appearance. In gathering, they should be pulled or twisted at the base, so as not to disturb the successional crop. When the beds appear to be dry, a good soaking of weak liquid manure, at the same temperature as that of the house, will assist the development of later crops; but as soon as the produce is not sufficient to be worth gathering, the most economical plan is to remove the old bed and make a fresh one in its place.—G.

Wintering Parsley.—As few herbs are so continuously in demand as Parsley, a plentiful supply of it through the winter is always desirable. A good way to preserve it is to take some flour barrels, get a 2-in. auger and bore their sides with holes 1 ft. apart every way; put 6 in. of soil in the bottom of the barrel, then draw the roots of a good plant through the bottom holes, fill up with soil till the next holes are reached, draw in some more plants, and so on until the barrel is full; then put four or five plants on the top; place the barrels in a cool house where they can get plenty of light. The produce, in both quantity and quality, will be such as will not disappoint any one who gives the method a trial, and such barrels are not unsightly. The plants should be good and strong for this purpose, or the produce will be small.

Ridging up Soil for the Winter.—It is by no means as well known as it should be that digging over ground in the late autumn or early winter months is not only of no real service, but in many cases is positively injurious. Far better let the ground lie untouched, merely clearing off weeds if any such be present, than to merely dig it over. The immediate effect of digging is of course to ensure a fair, neat, even surface during the winter; but however necessary this may be in the pleasure grounds, where neatness is a primary consideration, it can scarcely be considered indispensable in the vegetable garden, where everything should be done to secure a good tilth for growing crops. When a piece of ground remains throughout the autumn fallow and untouched by the spade, it forms a firm surface, through which the rain, however heavy, works gradually, so that the great body of soil remains to a certain extent free and mellow, and is easily brought into good order by a few drying days in spring. In the case of newly-dug soil the effects are very different, as heavy continuous rain washes it into a sour pasty mass—that is to say, in gardener's parlance, it becomes "poached," so that a considerable amount of time is required to aërate it when planting time arrives. This will, however, be at once apparent, that the true way is to throw up the soil into ridges as high as can be conveniently done, thus exposing a maximum of surface to those purifying agents, frost and wind, which are thereby enabled to rush through it and seize hold of every particle, purging it of all impurities and leaving it ready to the hand of the grower in as sweet, fine, mellow condition as he can well desire. It is needless to enlarge upon the advantages accruing to the kitchen gardener by thus having his fallow ground ready as it were to his hand at any desired moment. Whenever he may wish to commit seeds to the ground or set out young plants, he has merely to choose a daytime, and having his manure ready, pull down the ridges, stir the soil well with the fork in putting in the dung, and finish off the work at once; thus oftentimes accomplishing as much in one day as would require a week when the soil has to be prepared and sweetened for the reception of the crops.—John Cornhill.

TREES AND SHRUBS.

SHRUBS FOR SMALL GARDENS.

From their many shades of colour and shapes of growth and foliage, shrubs are at all seasons as beautiful and interesting as flowers; and it must not be forgotten that many shrubs bear very beautiful flowers in addition to beautiful foliage. In almost every garden there is room for improvement in the character of the shrubberies. There is too much sameness, too little variety; everything is reduced to one dead level; group after group is composed of the same materials of the commonest description. In more than one nursery during the last year or two I have seen the quarters filled to repletion with the best kinds of evergreens and flowering shrubs, and but a limited demand for them, whilst the demand for common Laurel, common Yews, Lilacs, &c., could not be met. In the annexed list I have omitted Laurels, for although they are beautiful evergreens that will grow in any soil and situation, they are not so well adapted for such places where it is sought to obtain the best effect in a limited space.

Where space permits there are many beautiful kinds of weeping trees, such as Sophora japonica pendula, &c., and where trees of larger growth are admissible, the Weeping Lime is a fine tree for landscape effect, and one of the most delightful trees to shade a garden seat. Among the large family of Conifers, too, selections might be made of the most beautiful and interesting character.

IMPROVING CLAY SOILS.

Having had considerable experience in the burning of clay soils in East Worcestershire, I can fully confirm the testimony of J. Rogers (given in Gardening Illustrated for Nov. 6) with regard to the beneficial effects of the operation. My plan, however, differs somewhat from

that which he recommends. Coals, in some localities, are more readily obtained than wood, but either will answer the purpose, although I prefer coals—the cheap kind, called "lumps," will do very well. Some fine "slack" also will be necessary, which may be had for about 3s. per cart-load. The tools required will be an old shovel—a good one would soon be spoiled—an iron bar, 4 or 5 ft. long, and a tool similar in shape to the "Burghley Cultivator," figured and described in an early number of GARDENING. I have long used a tool of this description, and find it invaluable in working stiff soils. I made mine from an old three-pronged potato-fork, by simply heating and bending the iron-work in which the handle was inserted, and fixing in it a handle 5 ft. in length. These, with a fork and spade, will be all the tools requisite.

We will now suppose that the top spit of a plot of clay land, say eight yards in width, has to be burned. Fork over one end of the plot the whole width and some six or eight yards in length; then, close to where you left off forking, and on the undug part of the plot, place about ½ cwt. of coals in a conical heap and set them on fire. While this is burning up proceed to build the *hearth* for your first fire, which must be in the centre of the part forked over. The soil should be in a firm state, so that it will break up in lumps or sods. With these sods, which may be about the size of a half-brick, form the outline of a rectangular figure, 6 ft. by 4 ft. Divide the space thus enclosed into six square and equal compartments by laying a partition of sods along the centre, and then intersecting this by two cross ones, each 2 ft. from the end.

Build up perpendicularly, in a wall-like form, both outline and partitions, till they are 1 ft. high. The outer wall, which may be about 6 in. thick, should be laid moderately close and firm, for the double purpose of preventing the egress of heat and the admission of too much air. By this time your heap of coals will be well lighted. Take your old shovel, and place the whole heap carefully in the six compartments, dividing it as equally as you can. Put on each fire a few lumps of coal, backing them up with small sods to keep them in place. While these are igniting build the outside walls—the partitions are now done with—6 or 9 in. higher, and as soon as your fires are all nicely established, cover them over carefully with small sods to the height of the walls. Throw over these a few shovelfuls of finer clay to fill up the interstices, and level the surface. You may now commence to build another hearth, 6 or 8 yds. from the first, but while doing so, keep an eye sometimes on your fire. Should it appear not to be burning freely admit air by thrusting in your iron bar in about half a dozen places at the very bottom of the stack.

As soon as the fire has risen to the top sprinkle over it two or three shovelfuls of slack, and throw on 6 in. more of clay, still keeping the walls erect. Repeat this process as often as the fire reaches the surface; but when "making up" for the night give an extra layer, and cover with 3 or 4 in. of shovelings. Should this prevent the issue of smoke, make with the bar two or three draught holes in the top, and cover each with a sod of clay. In the morning, if all has gone well, the fire will have penetrated the whole mass, and must be at once "drawn out." Take the three-pronged "cultivator" and rake down the walls all round, and then over this the hot ashes from the centre, which will effectually cook any of the partially-burnt sods. Give a good sprinkling of slack, and cover in quickly with sods and shovelings. Build a wall of sods round the outside of the upper edge of the heap, and proceed as before till the whole of the portion forked over has been used up. When this is done draw out the fire well from the centre, and throw in any unburnt sods that remain, which will complete the process.

As I have proved this mode of burning clay soils to be both successful and economical, I can strongly recommend it, and its superiority to the common way of burning in conical heaps will, I think, at once be apparent. If wood be employed instead of coals, it may either be reduced, if too large, to the size of the compartments given above, or these made larger to admit it. Old, uncleavable blocks, stumps, and butts of trees may be utilised in this way by surrounding them with walls of clay, and firing the stack with a shovelful or two of live coals. —J. MARTIN.

Moles, Snails, and Wireworms.—Having seen so many questions asked about moles, wireworms, and snails in GARDENING, allow me to give my experience of them. First the moles. Last year they gave me great trouble, so I set to work to get rid of them. Our cat killed four in one week, and I the rest with iron traps, but the result was I got a worse enemy—the wireworms. I had two very fine beds of Shallots, and the tops were all decaying, so I pulled them up to see the cause, and there were as many as sixteen wireworms at one root. Since then I have encouraged the moles, and I have far less wireworms. Now about the snails. I never had so few as I have had this year; the reason is I got as many toads as possible, and as they feed on snails and slugs they have kept them down. One of your correspondents says he has seen snails crawl under toads and they have not eaten them. He must bear in mind they are not always hungry. I have a toad in the greenhouse that will take a slug or snail from a pointed stick and eat it. —B. B.

GLASSHOUSES & FRAMES.

Alocasia metallica.—This is one of the most distinct and beautiful of fine-foliaged

Alocasia metallica as a vase plant.

hothouse plants, striking in the form of a large specimen, and equally serviceable and effective as a small vase or table plant, the young foliage being especially lustrous and handsome. For very large specimens, we select five or six of the strongest crowns or root-stocks, and taking some 15-in. pots, fill them one-third full of crocks, over which is placed a good layer of fresh Sphagnum Moss, to keep the soil from being washed down and blocking up the drainage, as, during the growing season, abundance of water, both at the roots and overhead, is required. The compost which we use consists of fibry turf, peat, charcoal, broken potsherds, and chopped Sphagnum Moss. The crowns or root-stocks, which are long in shape, are raised well up in the centre, packing the soil amongst them, so as to form a cone. If potted in February, they will throw up a quantity of flower-spathes before the foliage, but these should be broken off as soon as they appear, in order to direct the whole energy of the plants to the formation of fine foliage. Smaller crowns, placed three in a 6-in. pot, make fine vase plants in autumn and winter, and single crowns in 3-in. pots are also highly effective in table and plant stands, their polished, shield-like leaves contrasting well with whatever they may be associated. A moist temperature of 70° in spring suits them best; but in winter 55° will be ample. They may be increase rapidly by means of small root offsets. They are not liable to attacks from insects, but a sponging occasionally ensures cleanliness, and greatly enhances the beauty of their leaves.—J. G. H.

Tropæolums for Winter.—Where cut flowers are in demand, few plants are more serviceable than the scarlet-flowered Tropæolum. Pots are unnecessary, as by planting out vigorous young plants in summer, and training them under the rafts of any cool house, abundance of flowers may be gathered from them throughout ithe winter. In addition to their value for yielding cut-flowers, the plants themselves, when well studded with blossoms, have a bright appearance at a season when good flowers are scarce.—S.

Propagating Harrison's Musk (Mimulus moschatus Harrisoni).—Those who wish to get a good stock of this Musk, and have only a few plants, should adopt the following method, which I have practised with success, namely: Take all the points of the shoots off the old plants at the third or fourth joint; these should be cut again at the second joint, put into 3-in. pots, and plunged in bottom-heat. That portion which is cut off the cutting should be treated as follows: Remove each leaf with a "heel," and dibble them into a compost of leaf-mould and sand, when they will readily strike root. I had two plants sent by post, and in about six weeks I struck three dozen and a half by the method I have just indicated; not one failed.—W. S.

Creeping Fig (Ficus repens) **as a Curtain Plant.**—Large numbers of plants of this are grown in some of the large nurseries to a length of 4 ft. or so from the pot. In small 5-in. pots these are placed along the edges of the central beds and hang down to the ground, gracefully draping the walls. Being easily moved, they are also useful for forming similar curtains in rooms.

Stephanotis floribunda.—It is not generally known, we believe, but it is a fact, nevertheless, that there are two varieties of the Stephanotis—one which is a profuse flowerer, and the other not. We at one time possessed large plants of both, and grew them under the same conditions, and while one flowered profusely, the other scarcely flowered at all. Nurserymen profess to distinguish between the two varieties by their leaves, but we never could discern much difference in that respect. There is no doubt, however, of the superiority of the one over the other for flowering, and buyers should take care they get the right sort. The Stephanotis does well in pure loam and sand and a little well-rotted manure mixed, and likes a stove temperature, but will succeed nearly as well in an intermediate house. —J. S.

Eucharis amazonica.—A short time ago I saw what I think to be an excellent plan of growing this beautiful Amazon Lily to perfection. This is generally grown in a stove-house and in a high temperature, but the plants I refer to were cultivated under the following treatment:—The bulbs were placed in a suitable mould, and then put on long planks of wood (supported by bricks), just over the pipes, which ran through a bed in a moderately heated greenhouse, and then small oblong boxes of tin, curved in the centre like a saddle, made to just fit over the top of the pipes, were placed under the rows of Eucharis. These boxes were kept constantly filled with water, and the heat of the flues caused a continual heat and moisture to surround the plants. Certainly I never saw a finer-looking lot of this splendid Lily, and they, one and all, were as healthy as could be desired, after a long period of profuse blooming.—W. A. G.

Jasminum grandiflorum.—I was pleased to see this delightfully-scented variety of the Jasmine figured in GARDENING ILLUSTRATED lately. I find it succeed either as a climber or pot plant, and thrive in the greenhouse all the year round. Propagation is effected by cuttings in spring under a bell-glass and in a little heat; but as the plants can be bought so cheaply at the nursery, and at this season coming freely into flower, let me recommend no one to propagate their own. Loam, peat, or well-rotted leaf-mould, sand, and a little Standen's Manure make a good compost for it; and potting should be performed in spring before the summer's growth is much advanced. Pot plants will require cutting back a little when straggly, after which their growth must not be interfered with, as the flowers are

produced in trusses at the ends of the shoots, and continue to unfold in succession for some months. Climbers may be pruned also before starting into growth, and if they are allowed space to grow, and light, and are not hampered too much by tying and training, they will make a good quantity of fresh wood, and produce abundance of flowers. It is one of the best sweet-scented greenhouse plants—not much inferior, indeed, to the Stephanotis—and is little troubled with insects or disease.—S. W.

Ixias in Pots. — Few spring-flowering bulbs give so little trouble and are at the same time so full of grace and beauty as these ; either in pots in the greenhouse or in frames, or in protected beds merely for their flowers for cutting they are alike valuable. They may be potted firmly now, six bulbs in a 5-in. pot, in sandy loam and leaf-mould ; place the pots in a cold frame or on a shelf in a cold part of the greenhouse ; keep the soil dry at first, but give water more freely when the plants are in full growth. In April most of the varieties will flower, and will be very useful, as they are quite different in appearance from most plants at this season. When they have done flowering gradually dry them off, and allow them to rest till autumn, when they should be re-potted as before.—H.

Flowering Stephanotis in Small Pots. —Few sweet-scented flowers are more appreciated than those of the Stephanotis, either in a cut state or on the plants, and to have them in abundance on plants grown in 6-in. pots is desirable. This may be accomplished by obtaining strong young plants and growing them on in a moderate temperature, where they can obtain abundance of light, sun, and air. In summer they may be placed out of doors in a sunny spot, where the wood will get well ripened. The side shoots should be spurred in to within 1 in. of the main stem, and, when bad weather sets in, the plants should be removed indoors and their shoots tied up to a trellis near the glass. If a little heat be applied in November, shoots will be emitted at every joint, all of which will flower profusely. Large plants may of course be treated in the same way ; all that is required is to treat them exactly as one would Vines on the spur system, and abundance of flowers will be the result.—S.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

December 13.—Putting Cypripedium spectabile in a large pan in Sphagnum, peat, and sand, and placing it in a cold house, keeping it wet ; planting Souvenir de la Malmaison Roses in front of houses for autumn flowers, also Box hedge for shelter; putting in more forcing materials, including plants for cut flowers, and Sweet Briers and Roses for stands ; beginning to place show Pelargoniums in their flowering pots, using a compost consisting of loam, manure, and sand, and stopping them ; putting a few Fuchsias into heat for cuttings ; beginning to paint Peach trees in orchard house ; mulching all young fruit trees with manure ; looking over Pelargoniums, and picking off damaged foliage ; beginning to clear up Mint, Horseradish, and other beds.

Dec. 14.—Planting Seakale to produce seed next year ; bringing out of Seakale shed some Hyacinths which are pushing freely, and plunging them in Vinery ; putting in Deutzia gracilis, Anne Boleyn Pinks, and fancy Pelargoniums to force ; putting Endive under cover, and ashes over Peas to protect from birds.

Dec. 15.—Forking over in a shallow manner Raspberry ground ; putting Lilium auratum into peat and sand ; planting Stephanotis in loam and peat ; getting Fig trees into heat, 58° at night, and 63° by day, and plunging them ; putting in more Mint and Balm to force ; putting into heat Roses, Pinks, Cyclamens, and Heliotropes ; pruning and cleaning among Roses used for distillation.

Dec. 16.—Inserting Fuchsia cuttings ; putting in Dielytra to force, and a fourth batch of Asparagus ; tying up Yew trees, Cedars, &c., in order that snow shall not break them down ; finishing, painting, and tying orchard house trees.

Dec. 17.—Potting off late-sown Calceolarias, also Canterbury Bell and Cucumber plants ; putting a few white-flowered Pelargoniums into more heat, in order to induce them to open purer in colour ; shifting herbaceous Calceolarias ; putting litter over Parsnips, Seakale, Artichokes, Celery, Carrots, &c., in order to be able to get them up during frost ; sponging Palms, and Orange trees ; emptying a pit and refilling it for Potatoes ; putting manure on Asparagus beds ; thinning Mignonette and Nemophila.

Dec. 18.—Potting Isolepis gracilis for drawing-room decoration, also Vallota in peat and loam, and Dendrochilum filiforme in peat fibre and Moss ; placing in Peach house Daphne indica to force ; putting in also more Seakale and Rhubarb for the same purpose ; placing mats over hand-glass Cauliflowers during severe frost ; extra-strawing Lettuces and Calceolarias, and also Vine borders ; examining Orchids in little baskets twice a week to see if water be needed, those in large baskets once a week, watering those in pots at intervals of from seven to fourteen days ; putting ashes over Chervil seed.

Glasshouses.

Eucharis amazonica.—There is no particular season for the flowering of this plant, as with sufficient stock and the help of houses with different temperatures, it may be had almost continuously in bloom. Strong vigorous plants that have been well grown, and had a short rest, if now put into the forcing pit, and plunged in bottom-heat, will very soon throw up flowers. The best way to secure a continuous supply of these flowers is to vary the times of growth and rest with different portions of the stock, so as always to have at command some that are in a fit condition for introducing to a brisk temperature. This will be much better than treating the plants to a more uniform season of growth and rest.

Lily of the Valley.—This plant is a general favourite, yet it is frequently not near so well done as it might be, often through the use of home-grown roots, the cultivation of which has not been such as to impart the strength to them necessary to ensure a full crop of flowers ; though, where a suitable position is chosen, and the little attention required is given, it may be grown as well as the fine roots so largely imported, the crowns of which, under fair treatment, will not one in a hundred fail to produce flowers. It is well in the case of home-grown roots to select the strongest in the same way that is practised with those imported, leaving the weaker portion for replanting until they have acquired strength sufficient. There is nothing gained by giving the crowns of this plant intended for forcing more pot room than just sufficient to hold the roots without too much compression. Pots 5 in. or 6 in. in diameter are better than larger, as if the plants are wanted when in flower for decorative purposes, the small pots give facilities for them, standing where larger ones could not be admitted, and small examples are little inferior in effect. The roots, as soon as potted, may be at once placed in bottom-heat of from 70° to 75°, plunging the pots sufficiently deep to admit of 1 in. or 2 in. of material, such as old tan or leaf-mould, being put over them, which covering will help them to move much quicker. In the course of about a fortnight the crowns may be expected to have advanced sufficiently to admit of their being taken out, as if allowed to remain too long in this position they will become drawn. When taken from the bottom-heat, they should be stood in the body of the house or pit, and covered with two or three thicknesses of paper, such as will subdue the light, gradually removing the paper as they will bear full exposure to the light, for, like Hyacinths and plants of similar description, if the young growth, whilst in a blanched condition, is suddenly exposed to the light, its effects are injurious. Where a temperature of 65° to 70° can be kept up, the flowers will progress apace, and may be looked for being in for use in a month from the time the roots were put into heat. These details are given, as they may be of use to many who have hitherto treated this plant in a way that used to be common, the results of which were often unsatisfactory.

Hyacinths, Narcissi, and Tulips.—These may be introduced to a warm pit or greenhouse as soon as they have made enough root progress, but until in this condition it is no use subjecting them to heat, as, however strong the bulbs may be, unless they possess enough feeding fibres, the flowers will not come strong. It is not well to hurry plants of this description so early in the season as this, and as soon as the crowns have got gradually inured to bear light they should be placed sufficiently near the glass to prevent their leaves being drawn. Hyacinths and Narcissi are frequently seen with lengthened foliage, so weak as not to be able to support itself, and the flower-stems similarly elongated ; in this way they have not a pleasing appearance, to say nothing of the flowers under such conditions being very much sooner over than they should be.

Crocuses, Snowdrops, and Scillas.—The former of these has been long used in quantities for forcing, and the two latter are equally suitable and give variety, all coming on with less heat proportionate to their natural disposition in blooming early with a low temperature ; but where Scillas are forced, strong stout roots should be used, the flowers produced by which will be found very different to those forthcoming from weaker examples.

Lilac.—This is undoubtedly one of the finest of all forced winter flowers, especially manageable in the size of the plants, where these have been grown and properly prepared for forcing, as other shrubs more generally used for the purpose. It will bear more heat without in any way weakening or rendering the flowers liable to flag than any other plant usually employed for forcing ; but to have the bloom white, such as the Continental growers produce, the plants must be darkened whilst being brought on into flower ; it should be kept moist, the plants being freely syringed.

Such subjects as the double Prunus and Deutzia gracilis may also be placed in a warm temperature, and if plants are available that have been forced in previous years, particularly of the Deutzia, which, after flowering last season, were allowed to make growth in some heat, say a Vinery or Peach house at work, the growth will have been early matured, and they will bloom much better with little forcing than those that have made their growth in the open air. As this is one of the best and most useful of all forced shrubs, or, in fact, plants of any kind for winter flowering, it should be grown in sufficient quantity to keep up a succession until the spring. Any Rhododendrons are put into warmth so early as this, it should only be the kinds that bloom naturally early and too soon in the open air to escape frost.

Flower Garden.

Auriculas.—Compost may be prepared for surface dressing the plants when the time comes. As much as is likely to be required may be prepared and stored in a dry place. The compost for this purpose should be much richer than that required for potting purposes—say two parts of good loam to one of rotted manure, with a small portion of leaf-mould, sharp sand, and pounded charcoal. Many growers are very careful to frequently turn over the compost which it is intended to use for potting purposes during the winter, but more harm may be done in this way than by allowing the heap to remain undisturbed. Stack the loam in a heap, so that the wet can be thrown off ; have the compost mixed and laid up in the shed about three months before using it. The labels are apt to be defaced by exposure, and it may be well now to see to renewing them.

Hollyhocks.—These need little attention at present ; they are quite safe where planted out in cold frames. Those on shelves near the glass in a cool house, from which frost is excluded, will require water when they are dry, but the plants do not like much wet at this season.

Pansies in Pots.—These are also at rest. We plunged the pots this year in dry Cocoa-nut fibre refuse in preference to placing them on a stage. The plants were not so early established as they ought to have been for such an early winter. In all cases where an early bloom of any of these hardy flowers is required, it is very desirable to propagate the young stock early and pot the plants some time before there is any chance of severe frost.

Fruit.

If frosty weather prevails grub up old fruit trees, cut out all the dead wood in orchard plantations, and otherwise thin out the branches, particularly such as are crowded and intersect each other. All Moss or Lichen should also be rubbed off them, and if afterwards they can have a good splash over with newly-slaked lime, this will prevent the Lichen from growing again for a long time to come, and so put an end to a convenient harbour for insects. Usually, such orchards are on Grass, and, in the matter of manure, are left to take their chance, a circumstance more attributable to custom than to any real feeling that manure is not required, which it most certainly is, in order to ensure fine fruit.

A good dressing of stable manure ought to be given every alternate year, and if this be scarce, soot and wood-ashes form a most excellent substitute, and should be applied now, in order that the winter rains may wash them down to the roots before growth commences. By thus annually devoting a few days' labour to old orchards, they might be made much more remunerative.

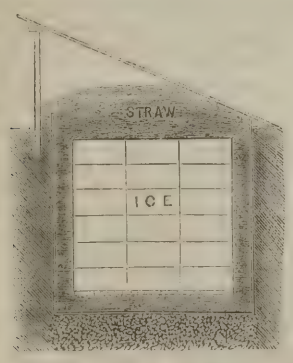
If the sorts are not the best, and the trees are healthy, this can soon be remedied by grafting; and when pruning good kinds the shoots should be saved for grafts, and heeled in at the base of the trees till required in March. The trees that have to be grafted may be headed down at once. Cut off all ground suckers with a spade. Whilst the ground is hard through frost let all wheeling of manure and soil on to the fruit quarters be done; also clear up all prunings, hedge-clippings, and vegetable refuse of every kind for burning, the ashes from which is a valuable fertiliser for any crop. Though it seems wrong to prune trees in frosty weather, we have never noted any ill-effects from it; but we would recommend that only the commoner and hardier kinds be done, and this solely with the view of forwarding the work. Currants, Gooseberries, and Raspberries may all be done in such weather as that we are now experiencing without any risk of danger whatever.

In order to effectually cleanse the trees from American blight, much pains will have to be taken to first of all wash it off with hot soapy water, and then to paint over the affected parts with a strong solution (8 oz. to the gallon) of Gishurst Compound, or a strong solution of soft-soap water and ½ pint of paraffin oil added to 3 gallons of the solution is equally effective. A greater quantity of the oil might prove fatal, but this amount we have proved to be both safe and a sure destroyer of the insect.

Amongst all hardy fruits, Peaches and Cherries are the most subject to attacks of aphis early in summer, and, by way of prevention, these should always have a winter dressing of the solution just named. Cherries may have it as strong as recommended for American blight, but Peaches should have the Gishurst at but 4 oz. to the gallon of water. The walls as well as the trees require dressing, and these we do with soapsuds fresh from the laundry applied with the garden engine. Such an annual dressing, by preventing attacks of aphis, saves a large amount of labour and annoyance in the early summer months, when, through pressure of other work, it is difficult to find time to attend to them. As soon as the frost disappears, push to a close all arrears of draining, trenching, and forming fruit tree borders, in order that the ground may get consolidated before planting the trees, which ought now to be delayed till February. See that recently-planted trees are securely staked, and that both these and all that require manurial aid should at once have a thick covering of the best manure at command.

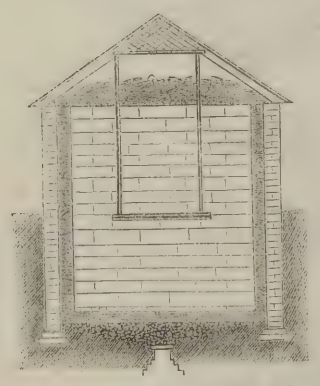
CHEAP ICE HOUSES.

I HAVE seen an ice-house (if, indeed, it was worthy of being called a house) made by excavating a pit 8 ft. square, and 8 ft. deep, into a bank of gravel that was so porous that the drainage from the ice was amply provided for. The sides of this pit were lined with 2-in. plank; the bottom covered with fine spruce boughs, and



Section of an Ice house.

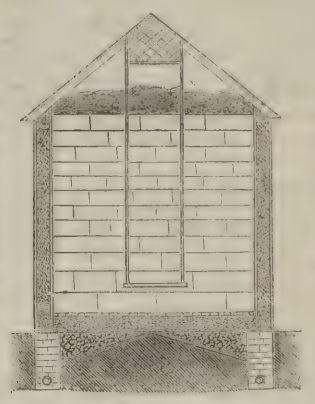
wheat straw to the depth of a foot. On this strips of old fence boards were laid, covering, perhaps, one-third of the whole surface. On these boards a cube of ice, 6 ft. on all its sides, was placed. The ice was cut in cakes 2 ft. square, and carefully laid, and having square edges, and being of uniform thickness, there was but little air between them. Over this 6-ft. cube of ice a foot or more of straw was placed, and the space between the ice and the plank on all of the sides of the pit was also filled with firmly packed straw. To keep out the rain some boards were placed over all, one end on the ground, the other on a piece of slanting supported by stakes driven into the ground, and about 4 ft. high. The ends and one side of this slanting roof of boards were open to the weather, and the winds blew freely over the straw that covered the ice. In this rude affair the ice kept well, and supplied the family all the summer with all they wanted. I do not say that this ice-house of least cost is the best that can be made, but, cheap as it was, it was made so as to comply with the great requisites involved, and it did perfectly envelop the ice in a good non-conductor of heat, and it kept that non-conductor dry by good drainage at bottom, and a free circulation of air on top. Sawdust is better than straw, but sawdust was not so conveniently had, and the difference between the two substances is not so great as is generally supposed. I have tried both straw and sawdust for many years, and now think that the principal value of sawdust over straw for packing ice is to be found in the convenience of handling, and in its lasting qualities. Sawdust may be used, if properly managed, over and over for many years. There is considerable difference of opinion in regard to whether the ice-house is best when all above the surface or all below. In reality there is nothing in this point, and each person will suit his convenience in regard to it. In a clayey soil, where drainage is difficult, it may be best to build all above ground,



Ice house –partly below ground.

and in large structures it may be best to put them all above ground, but for a small ice-house, intended to supply only a few families, and which is to be filled by the hands of men, without the aid of horses or steam engines, convenience in filling will be promoted by having a part of the ice-house below the level of the surface of the ground. The sill of the door should be just level with the top of the sled that brings the ice, and the door sill should be half way from the bottom to the top of the ice when the house is full. In this mode of construction, half the ice will be lowered to its place, and the other half raised. The door should be 3½ ft. wide, and reach to the roof. The air should circulate freely over the top of the sawdust or straw, or whatever substance is placed on the top of the ice. If this point is not regarded, the moisture that will rise up from the ice, or that will condense from the air, will in hot weather make the covering damp, and if damp it will decay, and cease to be the good non-conductor it was, and the ice will waste from the top.

Wooden Ice Houses.—Planks rot out very soon when used for the walls of an ice-house, and when the house is partly under ground the decay of timber is so rapid that brick or stone will generally be found more economical—not that a stone-house keeps the ice any better than one of wood, but it lasts longer. Some twenty years ago I constructed an ice-house for the use of several families, that I consider so well adapted to ordinary people's use that I give herewith a drawing that will enable any person to make one like it. Between the stone walls and the ice is a space of 1 ft. that is to be filled with sawdust, and the bottom is made, as shown in the drawing, by giving the natural earth a hopper-form, and in the middle sinking a well into the gravel several feet, and stoning it up so that its top is covered by a flag, and over this is placed loose stones, principally the spalls made from the walls in the course of their construction. When so levelled up, the whole was covered 1 ft. deep with spruce fir boughs, laid with some care, and enough of them to be 1 ft. thick when loaded by the ice. On these boughs



Wooden house—all above ground.

were laid narrow boards to make all even, but with wide cracks between, covering about two-thirds of the whole space. The roof is simply an ordinary shingled affair, with no attempt to keep the heat from going through it. Nor is there any shade-tree to keep off the sun, but there is over the door an open lattice-work, and in the back end of the building another that allows a free circulation of air, but does not allow birds or other like unwelcome guests to go in.

How the Ice House is Filled.—For convenience in filling, the door is taken off the hinges and placed out of the way. In the centre of the roof a hook is placed, in which a single tackle-block is fastened, and a rope passes through it, one end having strong ice-tongs attached that grasp a cake of ice on the sled, and men on the "fall" hoist, and others on the sled push, and the cake is swung in and placed without breaking. On the bottom described we place the cakes, 3 ft. long and 2 ft. wide; twenty-four of them make one layer. Having raised the ice 2 ft. or so high, we place sawdust around it and tramp it down hard, filling the space of 1 ft. thick between the ice and wall as solid as we can. More ice is then placed, and the filling goes on, the sawdust being kept along with the ice until the cube of 12 ft. of ice is completed. Over the whole sawdust or straw is filled, so as only to leave space for entrance to get ice and for circulation of air. In the door-jambs cleats are fastened, against which short moveable boards are placed as the ice is put in to hold the sawdust against the ice in the doorway. These short boards are taken out as the ice is used in summer. This ice-house has been filled the twentieth time, as far as memory serves me; the bottom, of spruce fir boughs, has never been moved or replaced, and there has never been a time when the house did not have ice in it, except when we have cleared out some cord or two each winter to make room for a new supply, and we use the same sawdust over, having generally to renew each season about as much as a waggon load—say 40 bushels—to make up for waste. The only change made has been to remove a lining that was originally put in. This lining was simply inch boards nailed to wide studs, and was intended to hold the sawdust of the sides in place. In about three years the boards had so rotted that we renewed them and the frame to which they were fastened, and since then we have placed our ice and filled around it as described. I have only mentioned this attempt to line the ice-house with boards to show how vain the effort proved to save the labour of moving the sawdust out and then taking it back each year.

Ice House above Ground.—Ice-houses all above ground are, in places where drainage of one partly underground would be difficult, perhaps the best. Their construction is perfectly simple, if made of stone or brick—and if made of wood are quite satisfactory as long as they last. The directions that follow will be sufficient. Studs, 12 in. wide, and 2 in. thick, and

12 ft. high, are placed on 2-in. plank sills of the width of the studs; these sills being placed on the top of gable wall that fills a trench 2 or 3 ft. deep, give the outlines of the frame. Board on these studs, both sides, with well-nailed inch boards. Fill the spaces between the boarding and studs with well-rammed sawdust reaching from sills to top of studs. Make a floor as described for stone ice-house, partly under ground—only reversing the form of the earth under—that is, making the centre higher than the sides, that the water that forms from the ice may run freely outward to the drains under the sills. An ice-house so constructed will be filled out to the boarding of the sides, and covered over with sawdust or other non-conducting substance.

Packing Ice.—This point is of less importance than is usually thought. Convenience of handling requires that the cake should not be much over 8 in. or 10 in. thick, and half that thickness will keep well in summer if properly packed and cared for. The dealers of ice generally place the cakes on their edges, as they are every day, during the season of consumption, taking out of the house large quantities, and it is convenient to take hold of the cakes with the ice-hooks when they are standing on edge. But for ordinary family use, I always prefer placing the large ice cakes flat-wise, as, by removing the covering, it is easy, having a proper tool, to cut the cakes as they are found into convenient pieces for use, exposing but little surface to the air while taking out the supply. I think the ice keeps better when the widest parts of the cakes rest on each other. Less air finds its way between. But this is principally a matter of convenience. Persons who have not tried freezing the whole mass of ice into one solid body are often giving advice to use water on a cold day to freeze the cakes, and fill up all spaces between them with ice thus made. Quite likely such a solid mass will keep well, but the difficulties attending chopping it out, and breaking it into chips and splinters as used, are so great that such a mass of ice is of very little value. I have tried this plan, and have made ice in the house by using a jet of water that froze as it fell, and formed a solid mass, that the next summer was of very little value, as it could not be taken out in any convenient form, and the labour of chopping it out was more than would have been required to cut, draw, and place in the house. And I have tried freezing the cakes into a solid mass by using chips and water in a cold day, and have given up all such notions.—*Tribune.*

FLOWER GARDENING.

A very decided change has lately set in with regard to small flower gardens attached to villa residences, that proves how much more powerful example is than precept. For I now find that owners of these little gardens take note of the changes they see in public gardens, or such as by the liberality of their owners are thrown open to the public for certain portions of the year, and are copying the prevailing fashion of turfing over unnecessary beds and walks, and throwing the additional space into the lawn or Grass plot. Generally a bed or border all round is now the fashion, for under the shelter of the dwelling house many comparatively tender plants may be grown, and by the roadside or exposed ends some rather tall shrubs are desired for to ensure privacy, and in front of these herbaceous plants and bulbs with annuals in summer make an effective display. Where the turf was for years cut up with a lot of sharp-pointed, angular figures that no one could fill properly, much more cut the Grass in the niches of turf left without injury to the flowers, one or two good-sized beds of simple outline have replaced them, so that the little mowing machine may pick up every particle of Grass without damaging the contents of the beds. I find, too, that the plan of getting a few shapely little Conifers from the nurseries for furnishing the beds in winter is taking the place of having bare beds for half the year, and by planting common bulbs and surfacing the soil with Forget-me-nots, Silenes, or Pansies a very pretty effect is produced in spring. A good specimen Holly or other evergreen shrub now generally marks the site where the beds have been turfed over, not only with advantage to the labour of keeping in good order, but also for the general effect at all seasons. J. G.

Linton.

A Winter-flowering Honeysuckle.—Flowers that are so delicately perfumed as those of the Honeysuckle have a special value in winter, and as Honeysuckles can be easily forced and had in bloom at that season, the wonder is that they are not more largely grown for the purpose. There is one variety, however, I think not generally known that flowers naturally about Christmas, the name of which is Lonicera fragrantissima, and although not so large and showy as some, it is of great value for working into bouquets or using for button-holes, for either of which purposes its pale, highly-perfumed blossoms are particularly adapted. If grown in pots and kept pinched in so as to induce a lot of small twiggy shoots, it is very floriferous, as also when trained to a wall having a sunny aspect, and treated in the same manner, as every joint or bud then emits blooms, which are produced for some time in succession. The great advantage of growing this particular kind is, that without any artificial heat whatever the sweet odours of this favourite class of plant may be enjoyed at a dull time of year, as all it requires is a little shelter from the wintry blast, and, with this afforded, quantities of flowers may be gathered from it. The best way to treat it when used as a pot plant is to spur or prune it back a little every spring just before the young growth commences, so as to get as many fresh shoots as possible, the heads of which, nipped out well, as above mentioned, cause them to break again and form fine bushy heads. Two or three of these placed in a greenhouse would quite scent the air, and last till any of the other varieties can be got in. The best of these for forcing are the shrubby kinds, such as Ledebouri, præcox, odoratissima, and Xylosteum, but most of the climbing varieties are amenable to the same treatment, and when somewhat stunted in pots partake a good deal of the habit of the former. All the different sorts of the Honeysuckle may be propagated in several different ways, and cuttings put in now of the half-ripened young wood will strike freely under glasses in sandy soil on any open border, or they may readily be increased by layers, but these take a year to root sufficiently to be severed from the parent plant. Short pieces of the tender growths taken off with a heel in the spring and placed in moist heat soon make plants, and this is the most expeditious mode of working up a stock.—S.

Winter-flowering Honeysuckle (Lonicera fragrantissima).

East Lothian Stock.—This is one of the very best hardy flowering plants which we possess. It has many good qualities to recommend it, being pretty in colour, sweet-scented, and of easy culture. When cut it will last eight or ten days, provided the water is changed occasionally. A good bed of it is most useful where cut flowers are in request. We have a row of it which up to the present time has been a mass of bloom, and they have been in that condition since July, notwithstanding that baskets of flowers have been cut from them for decorative purposes. The seed was sown in boxes in February and put into heat; when the seedlings were well up they were removed to a warm, light pit, and gradually hardened off until May, when they were planted about 15 in. apart, alternate plants being of different colours, consisting of scarlet, white, and purple. They very soon established themselves, and grew rapidly until July, when they met in the rows, and began to bloom profusely, with scarcely a percentage of single ones among them. They now look like a dwarf hedge, 18 in. high and as much across, and, as has just been stated, they are a blaze of flowers, and have the appearance of continuing in blossom till Christmas, should the weather keep open.—W. W.

Fuchsias for Planting Out-of-doors.—It is much to be regretted that growers of Fuchsias limit themselves almost exclusively to hybrids of garden origin, disregarding, or nearly so, the important species which we have had so long; for instance, it is seldom one meets with that fine old plant Fuchsia fulgens, and still seldomer do we see F. corymbiflora in good condition. Many years ago I met with both these in a garden a few miles from Windsor, planted out in beds in the flower garden, the first-named being from 6 ft. to 7 ft. high, the last one still higher. I think they were taken up in autumn and stowed away after the manner of Dahlias, and they well repaid the trouble, as the flowers, like those of all the section, being of a pendent character, are not so effective when seen on small plants as on large ones, and both kinds can be raised from seeds. There is also a small variety very seldom met with, and for many years I lost sight of it altogether, but I eventually ran against it in an old garden in Surrey. It used to be called F. parviflora or F. microphylla. It is a pretty little kind, and ought to be more generally grown than it is, as it is a most abundant bloomer. There are also, I believe, one or two other species distinct enough for ordinary hybrids to be entitled to a place in collections, but the kinds which I have named are pre-eminently so.—A Retired Gardener.

Canterbury Bells.—I have lately filled a border, about 120 ft. in length and 7 ft. in width, with nearly 300 strong plants of this fine hardy biennial. That such a mass of it will give a rich and varied effect next summer I have no doubt. The only drawback is the hot, dry weather that generally prevails in June and July—the blooming period—which is apt to affect this Campanula. It is therefore well to give the individual plants plenty of room, in order that they may have all the moisture possible when most required. If seed be sown in pans or boxes in the month of April, the young plants so produced will develop fine compact heads of foliage, and in this way will be quite ornamental in the borders during the winter. The flowers of the Canterbury Bell are most useful for house decoration, and, being borne individually on stems from 4 in. to 6 in. in length, are specially adapted for cutting. Some of the blooms are drooping, but in a good strain, where there is an abundance of the double forms of flowers, the blooms are more erect, and work well into nosegays, or are useful for any purpose. It is not difficult now to obtain some twenty or more distinct hues of colour in a number of plants, ranging from pure white to blue and purple, the rose-coloured tints especially being exceedingly handsome.

The plants also lift into pots easily, and when so treated, and plenty of water given them, will hold their flowers for a long time. When in pots they are exceedingly ornamental for the decoration of verandahs, corridors, halls, and other cool places.

Showy White-flowered Bramble (Rubus deliciosus).—This, though a very old plant, is not often seen in private gardens, but it is well worth culture, as one of the most striking of early-flowering shrubs. Our illustration was prepared from a finely-flowered plant in the Royal Botanic Garden, Regent's Park. Its large, white-Rose-like blossoms are succeeded by reddish-purple, Blackberry-looking fruits, which possess an agreeable flavour. The plant is perfectly hardy, and, like all other species of Rubus, may be readily increased by root cuttings. It may, we think, be obtained from Mr. Ware, of Tottenham, in whose nursery we have seen it finely in flower.

TOWN GARDENING.

Carnations.

These comprise two great classes, the tree or perpetual, and the ordinary garden kinds. The former grow to a great size, and are generally regarded as greenhouse plants, as, with proper treatment and in a genial temperature, they may be induced to produce their beautiful flowers in winter. But it is very difficult to get them to do so in a town; and as we are now dealing with out-of-door plants, we confine our observations to the ordinary Carnations which are by far the most suitable for the open border. Though it must be remarked, that if you have a low-roofed glass house without fire-heat in which you can grow and flower these lovely flowers in pots, you will succeed far better than by keeping them exposed. When planted out during summer they must be wintered in a cold frame or other suitable quarter; a sitting-room window will do.

Out-door Culture.—We will take the out-door culture first, and then give instructions for growing in pots for the benefit of those who have the conveniences for doing so. Nice healthy plants should be obtained about May; it is not advisable to plant out before the beginning of this month in towns. We prefer those that have been potted separately and kept through the winter in large 3-in. pots, or if forward, they may have had a shift into 5-in. or 6-in. early in spring, and be planted out from these. Choose a nice sunny position, sheltered from cutting winds, and prepare the border by digging it deeply, and incorporating a good quantity of thoroughly rotted manure; anything that has been burned in any way, especially such as charred turf, may be added in liberal quantities to the soil with advantage. But be careful to see that there are no wireworms in the soil, for these are deadly enemies to Carnations, and indeed to all the Pink or Dianthus family. Put the plants in firmly, and make the soil solid all around them. Water in dry weather, and when they run up for bloom, tie the stems neatly to slight, but sufficiently strong stakes. They will flower in July or August.

Propagating.—This is done in two ways, by layers and cuttings, or pipings. The first is the most simple and general. In August, as early as possible, take the "Grass" or shoots that have no show of flower upon them, and prepare a place for each by making as many shallow holes or "scoops" in the soil close round the old plant as there are shoots to be layered; and prepare them by putting a good handful of sweet, fresh, sandy loam, with a little leaf-mould mixed with it in the hollow for the layer to root into. Then, having some silver sand and a supply of large hair-pins or hooked twigs cut from Pea sticks or the like, take each shoot and with a sharp knife cut half-way through it in a sloping direction, and from underneath, just where it makes the bend upwards, or where the strong green leaves begin to cease, and the stem looks brown and shrunken. Put a little sand for it to rest on, and peg it down carefully into its place, putting a little sand round the cut, and a handful of the loam on the top; press all firm, and give a good watering to settle the soil. They must not be disturbed till November, when they will be rooted, and should be carefully lifted with balls of soil, and potted singly in 3-in. pots, using rich sandy loam. Keep them rather dry in a cold frame during the winter, with plenty of air on all favourable occasions, but keeping close shut up and well matted in hard frost. In spring plant out again as before directed. Cuttings should be taken earlier, and if any quantity are wanted, prepare a small frame for them by setting it on a bed of nice, sweet, mild, fermenting materials that will ensure a gentle and steady heat. Place a few inches of drainage in the frame, and on that some nice sandy loam. The cuttings should be 3 in. or 4 in. long, cut neatly just below a joint, or pulled out at the joint, and any film or fibre trimmed off with a sharp knife. Set these in the bed pretty thickly, and give a good watering, enough to make the soil like so much mud. Let the leaves dry, and then shut the frame up close, and admit little or no air until they are well rooted, which every one will be, if properly done, in about six weeks; then pot off singly in 3-in. pots. Keep close for a short time, then harden well, and keep through the winter the same as plants from layers.

Culture in Pots.—Good, strong plants, such as those described above, always choosing the best, should be taken about March, and potted direct into the pots in which they are to bloom. These may be 7 in. or 8 in. wide for one very strong one, or two or three, or even four may be put in a pot from 8 in. to 11 in. wide. The soil should consist of three parts good turfy loam that has been either partially burned or well exposed to the action of the frost out of doors, and one part of well-rotted manure, with a little crushed charcoal, and some sand if needed. Pot the plants very firmly, give a moderate watering, and place in a low, airy, and very light house—either a span-roof or lean-to will do, but the former, running north and south, is preferable. Give abundance of air and no shade. Water only when the soil is dry, and as the flower-buds expand give liquid manure twice or thrice a week. Thin out the buds if numerous; the first, or top bud, the third, and fourth or fifth, or sometimes both, are best to leave, as a rule. Stake as required. When the flowers are over remove from the house, and stand out of doors on boards or slates, to keep worms from entering the pots. To take layers from the plants prepare as many 3-in. pots as are required by putting drainage in them, and filling up with sandy loam. Arrange these round the old plant, and if all are plunged in some open material so much the better. Proceed exactly as for layering out of doors, but instead of a peg, a stone placed on each shoot just over the cut is generally used. When rooted, separate from the parent, and treat in the ordinary way.

Raising from Seed.—Carnations may be raised successfully from seeds. Obtain a good strain, and sow in spring or early summer in wide boxes of sandy loam and leaf-mould. Prick off and pot as required; they will bloom either in pots or the open ground the next autumn. The seed-pans and the young plants should be kept in cold frames till they are strong.

Picotees are generally associated with Carnations, but we do not recommend their being attempted in anything like impure air, as they are far more delicate and susceptible to climate than the Carnation.

Chrysanthemums.

There are several distinct varieties of this popular plant. The old fashioned early recurved (*i.e.*, having the petals turning outwards from the centre) comprising only a few varieties, of which the best known and most useful are the ordinary yellow, white, and red, are the most suitable for culture in towns where no protection can be given them. Not only are these hardier than the newer and more fashionable incurved kinds, but they come into flower much earlier, a great advantage, as the later ones almost always get cut off by early frosts if left exposed; moreover, it must be borne in mind that as the winter draws on the air gets more and more loaded with smoke and dirt every day, so that even if late flowers could be induced to open out-of-doors, they would be so dirty as not to be presentable. These early kinds require very little care. The ground should be well dug and manured for the reception of the plants, and once planted they will last for years, the only attention needed being to cut off the old stem down to the ground as the flowers wither, thin the shoots when they appear in spring, stake them as required, and give them a good soaking of liquid manure in dry weather in late summer and autumn. When the stools get very old it is advisable to separate and replant them, or get a stock of young plants from cuttings, and throw the old ones away.

There are also the beautiful new show varieties, many of which are incurved—that is, having the petals overlapping each other, and pointing inwards. These are by far the most beautiful, and should be grown by everyone who can afford them protection of some kind when in flower, but they will not do much good without. The flowers of some of these are as large and regularly formed as a Dahlia, and far more delicately beautiful.

Next come the Japanese varieties, some of which bloom even later than the last-mentioned, and thus keep up a succession of flowers far into the New Year. The blooms of these are certainly not so neat as those of the incurved, and almost deserve the epithet so often applied

Showy White-flowered Bramble (Rubus deliciosus).

to them by their non-admirers, of "ragged." Still, in their way, they are very beautiful, or at least some of them; the colours are very rich, and the flowers of several of an enormous size.

Then there are the Anemone-flowered Chrysanthemums, which we do not recommend, unless as a variation where a large collection is grown. And lastly, the Pompons claim a place. Many of these can be grown in towns, even entirely in the open, with as good results as the larger kinds, but the flowers are relatively small, and as a rule not very good in colour; still, grow a few if you have room.

Annual Chrysanthemums.—Besides all these, however, there are the very early or summer-flowering kinds (perennials) and the annual kinds, all of which do equally well. The former flower in July, August, and September, and are extremely bright and effective. We strongly recommend them. A few are Aigle d'Or, Cassy, General Canrobert, Illustration, Madame Picorel, and Scarlet Gem. The annual kinds are hardy, and should be sown and treated the same as other hardy annuals. The best are C. tricolor, C. Burridgeanum, C. hybridum, and double snow-white and golden. There are also two very good new kinds—"Lord Beaconsfield" and the "Sultan." Chrysanthemum frutescens, also known as Paris Daisies, or Marguerites, are very pretty and suitable for town culture.

Protecting from Frost.—If you have a greenhouse, or a few spare frame sashes or lights, by all means grow a few of the incurved kinds in pots, or even, if you have a bed or border facing south, and can rig up a framework over it, on which calico can be stretched, just to keep off the cold winds and soot, &c. In this latter case, do not bother with pots, but plant them out in deep rich soil as directed for the early ones, and in October get the framework ready, and stretch the calico, or whatever you have, over as soon as early frosts or cold winds warn you that the protection is needed. Anything will do to go round the sides—old sacks, so that there are no holes in them, or oilcloth; but for the top, which should be about 6 in. or 8 in. from the tops of the plants, as transparent a material as you can provide should be used. Glass is best, of course—the lights of frames not in use at this season coming in admirably. The covering must be partially removed, so as to admit air, whenever safe, especially if it is not glass, so as to give light as well, and on the fine, bright, and clear days we sometimes experience, remove the top altogether, and the sides, too, if it is very fine.

Incurved Varieties.—A dozen of the finest of the incurved varieties are:—Empress of India, blush white, very large; Eve, sulphur white, fine; Fingal, deep rose; General Bainbridge, amber; Jardin des Plantes, intense yellow; Mr. G. Glenny, pale yellow, splendid; Mrs. Dixon, deep golden yellow, fine; Mrs. G. Rundle, pure white, a superb flower; Pink Perfection, pink; Prince Alfred, rose crimson, fine; Venus, lilac; and White Venus, waxy white.

Culture in Pots.—In order to obtain fine large plants and flowers, if you can give them room, take your cuttings in autumn, but spring-struck plants are very good for ordinary display. In the former case take off the young suckers from the surface of the pots when they are about 3 in. long, just as the flowers are over, in the autumn—say November—and put five or six round the sides of a 3-in. pot, using a mixture of sand, loam, and leaf-mould. They will root freely in a warm greenhouse or frame, or they will do so in a cold frame if it is shut up close, and only a little air given on fine days, and well matted up in frosty weather. In this latter case the cuttings will take several weeks to root, but will make as good plants as the others.

Potting-soil, &c.—When they are rooted, which can be seen by turning the plants out of the pots, pot them off singly into 3-in. pots, using the same soil but not so sandy as for the cuttings. Keep them close for a little time after this operation, and if they can have a little gentle heat they will root out more freely; then accustom them to plenty of air. When the roots touch the sides of the pots shift them into 5 in. ones, using a mixture of turfy loam 3 parts, manure and leaf-mould 1 part each, with a little crushed charcoal and coarse-grained sand. This compost will be suitable for every shift onward from this stage. Continue shifting them on as they require it—that is, whenever the roots begin to coil round the sides of the pot rather plentifully, it is time to give them more room; remember, if you want fine freely-grown plants and large flowers, these plants must never become what is termed pot-bound—at least until the pots in which they are to bloom are reached; it is advisable that these should be full of roots by the time the plants show flower. From the 5-in. pots they should be shifted into 7-in., and from these into 9-in. or 10-in.; and, if early, they may have yet another shift into 11 or 12-in. pots; but they should all be in their blooming pots by the end of June, so that whatever size is reached by that time there let them stay. The plants must be kept under glass until the middle or end of April, when they may be placed out of doors, but must be kept from frost. When set permanently out in the open air the pots must be plunged two-thirds or three-fourths of their depth, or even right up to the rim, if possible, either in the ground or in a bed of tan, cocoa-nut fibre refuse, ashes, or other suitable material. This keeps the sun from the sides of the pots, or the roots inside would suffer, also to prevent the necessity for so frequent waterings as would be necessary if the pots were free all round. If the pots are simply stood upon the ground and the ashes or tan heaped round them, each one must stand on ashes 3-in. or 4 in. deep, or on a piece of slate, to keep worms from entering through the drainage hole; if sunk in the ground, make a tapering hole with the trowel only just large enough to take the pot up to the rim, but going down about 6 in. deeper, so as to leave a hollow space beneath for the same purpose. From the first the plants should have all the light and air possible, and plenty of room as well, and when put out of doors they must have an open and airy position, exposed to the full sun. Do not attempt to crowd them at all, but rather have only a few plants, if the room is limited, than too many for the space. Large plants in 10-in. or 11-in. pots ought to be at least 2 ft. 6 in. apart in a row, and if more than one row these should be 3 ft. apart, and, if possible, more. For unless the growth is made under these conditions, and so well ripened or matured, you will have but a few poor flowers, or perhaps none at all.

Stopping the Shoots, &c.—When the young plants, which should only have one stem, are 6 in. or 8 in. high, pinch out the top, so as to induce the formation of three or four side shoots. Do not do this immediately before or after a potting, but wait until the plant has become well established in its pot (we generally do this when in the 3-in.), then take out only just the extreme point, giving rather less water and air until it has "broken" well, and then more again; and when the young shoots are 1 in. or 1½ in. long, shift into the next size. Remember to keep rather drier and a little closer after each shift for a little while, until the roots are working freely in the fresh soil. The points of the shoots may be pinched out as often as they attain such a length, at the third joint, up to the middle or end of July, if you want to make the plants very bushy; but bear in mind that five or six stems are quite enough for a 9 or 10-in. pot to carry, so that, in general, twice stopping will be sufficient; also, that the less the plants are pinched, and the longer and taller the individual shoots have grown by blooming time, the larger and finer will be the flowers, though there will, of course, be fewer of them than if the plants had been pinched oftener. So that if you want dwarf, bushy plants, with plenty of flowers upon them, without so much regard to quality, pinch often; but if, on the contrary, you aim at getting a few fine flowers, and do not mind the plants being tall, only stop once or twice.

Watering.—Give plenty of water in all stages of growth; these plants should never be allowed to flag, and syringe or sprinkle overhead once or twice every day in bright weather, morning and evening being the best times. Manure water is not needed, if the soil is tolerably rich, until the flower buds appear, though some give it as soon as the flowering pots are full of roots; and if the plants appear to need it at this stage give some, but not before the pots are well filled with roots. Give the manure water, which may be a decoction of fresh horse or cow-dung, guano water, or anything suitable, alternately with clear water. Begin with it weak, and by degrees increase the strength to a moderate extent, as Chrysanthemums are gross feeders; reduce the strength, however, again as the days get shorter, in October, and discontinue it altogether when the flowers open.

Thinning the Buds.—When large enough to get hold of, thin the flower buds to two or three, or even one, on each stem, if you want extra fine blooms, for you cannot have quality and quantity at once. As soon as there is any danger of frost, or when the air gets dull and dirty, remove the plants under cover. A light, airy greenhouse, with little or no fire heat, is the best place, but a few spare frame lights, fixed sloping against a wall, 4 ft. or 5 ft. from the ground, or high enough to take the plants nicely, or even calico strained tight on a framework, for the top, and boards, old sacks, canvas, or anything fixed along the front, will make a suitable shelter, as before advised. Of course a light sitting-room window will take a few small plants, but beware of gas in the room—if used the flowers will never open.

Treated as above directed some of the earlier kinds will begin to open early in November, or even the end of October, and the flowers, either cut and placed in water, in which they will last for weeks, especially if covered with a bell glass or shade, or left on the plants, will delight yourself and your friends for a long time, and if a suitable selection is made, and some of the Japanese kinds are included, you will not want for flowers till the end of January or later.

The directions given above apply equally well to the cultivation of the Japanese and Anemone kinds, as well as the Pompon and Incurved varieties, all requiring almost exactly the same treatment, the only difference being that the Pompons do not need such large pots in which to flower as the larger kinds, and the late Japanese kinds need not be quite so forward as the others.

Of course when plants in pots are removed under protection they may be stood much closer together than when growing; indeed they will not hurt touching each other. This is one great advantage of growing in pots, as they may be grown with as much space, and packed as close when in flower, as you please; whereas those in beds must stay as they are. It is a good plan, if there is a south wall, to plant good Chrysanthemums close at the foot of it, and nail them up against the wall like a creeper. In this way they grow very well, and can easily be protected.

B. C. R.

(To be continued.)

ANSWERS TO QUERIES

3769.—**Cockscombs in the Dwelling.**—Our advice would be not to try to grow the Cockscomb in the dwelling. It is a plant that requires a large amount of heat and moisture early in the year, and there are so many fine subjects for window culture, that it is scarcely worth while to attempt the culture of one which requires conditions of growth of a rather peculiar nature. The same, to a certain extent, may be said of the Sensitive-plant, but if you sow the seed in a warm room in April, you would probably get fair-sized plants by the end of the summer. Sow in sandy peat, keep the soil moist until the plants are well up, and pot them off when large enough into small pots.—J. C.

3764.—**Pruning Marechal Niel Rose.**—This requires but little pruning, the operation being confined to thinning out all weakly shoots and shortening back the strong ones to about two-thirds of their length. Each eye left produces a shoot, which gives a truss of bloom, so that the longer and stronger the shoots the more flowers. There are two points to observe in the culture of this Rose. In the first place, it must be encouraged to make a strong growth every year; and secondly, as soon as the flowers have faded, the plant should be cut back hard, so that fresh, free, strong wood be again formed for the ensuing year. This is the only way to get fine blooms, and plenty of them, and accounts for the fact of so many failing to obtain good flowers after the first year or so, for when the old wood is retained the side shoots proceeding

from it are deficient in vigour, so that they cannot by any means give bloom of the finest quality. Maréchal Niel is really only fit for culture under glass, as, when growing in the open air, there is, except in very warm districts, scarcely time enough for the new wood to be made and matured after flowering. In the case of plants grown in pots, the best way is to train the young growths round some stakes inserted round the edge of the pot. When the flowers are faded, cut the shoots hard back, and either shift into the next sized pot, getting away as much of the old soil as possible, or top-dress with some concentrated manure. When growth is completed turn the plants out into the open for a time to harden them. Bring them in about the beginning of November, and prune them at once. Early pruning induces early flowering. —J. C. B.

3755.—**Culture of Lilium Washingtonianum.**—It does not follow because a plant comes from a country where the winter is severe that it is necessary, or even advisable, to expose it to the vicissitudes of our English climate, which is often characterised by periods of excessive moisture, followed by hard frosts, differing in that respect from the winters in many lands, which, although severe, may be more or less dry. Besides, it must be remembered that there is no comparison between a plant in a pot and one in the open ground, the conditions under which they exist being quite different ; so much so, indeed, that no good practical grower would think of leaving even the hardiest plant, when in a pot, unprotected throughout the winter. Keep the Lily in a cold frame, maintaining the soil in a moist condition until it begins to grow, when more water may be given. The fact of the summer being hot where the plant grows naturally will sufficiently indicate the general treatment. Ensure to the p ant a genial climate by keeping it under glass until the middle of June, giving plenty of air ; then place it in some sheltered situation. When coming into flower place it under glass, and allow it to remain there until the foliage dies off, then shift into the next sized pot and treat as before.—C.

3578.—**Ferns for Miniature Fernery.**—The following are all pretty dwarf-growing species : Asplenium trichomanes, Adiantum nigrum and viridis, Ceterach officinarum, Allosorus crispus, Woodsia alpina and ilvensis, Polypodium phegopteris and dryopteris, and the common Maiden-hair (Adiantum Capillus-veneris), which would in all probability thrive when protected by a glass roof. Selaginella helvetica and Kraussiana are two Club Mosses which require no artificial heat, and these might form a carpet from which the Ferns might spring forth. The best way is to plant them out in suitable compost, which should consist of half peat and loam, mixing with it some pieces of sandstone, brick, charcoal, or anything of a like nature, for these small-growing Ferns are not so vigorous of roots as the tall-growing kinds, and every care must therefore be taken to ensure the most perfect drainage. Raise the bed of compost well above the level of the ground, and let some of the larger stones peep out here and there through the soil, forming as it were pockets in which to plant. Many of the more miffy kinds love to find themselves close to a little stone boulder, and will often thrive well when thus situated much better than when placed out in free exposure. If the Fernery is to have a glass roof it should not be enclosed on all sides. Cover say the top and glass up the two ends, leaving it quite open in the front, which will allow of the inmates being inspected when required. Hardy Ferns love a cool, moist atmosphere and partial shade, but they do not like to be in confined quarters. Nothing is gained by shutting them in closely. There is a class of Ferns called hardy exotics, which will thrive under glass without artificial heat, but they are mostly of tolerably strong growth. Lastrea Standishi and opaca and Onychium japonicum might, however, be tried, placing them in the back line.—J. C.

3772.—**Roses in Pots.**—The plants in question may be brought into heat at any time between now and March. The first thing to do is to prune them, the next is to repot them if the pots appear to be full of roots, otherwise top-dress with concentrated manure. Gloire de Dijon must not be pruned back too hard ; strong shoots should have four eyes left on them, and Maréchal Niel should only have the strong wood shortened back a little, cutting out weakly shoots. The other kinds mentioned may be cut back to two eyes.—C.

3762.—**Climbers for Trellis.** — There can be nothing better for forming an evergreen screen than Ivy, which remains summer and winter fresh and green, and which forms a dense eye-proof mass. Regner's and the Irish are the best green kinds, and you might mix with them the clouded white. If Ivy is not wished for, then take any of the evergreen Roses, Cotoneaster microphylla, and golden variegated Euonymus. The best arrangement would be, we think—at any rate what we should adopt in a similar case—to plant in the first place some free-growing hardy climbers, such as evergreen and Orleans Roses, Clematis Jackmani, rubella, lanuginosa, candida, montana, and flammula, golden variegated Honeysuckle, Dutch Honeysuckle, Jasminum revolutum and nudiflorum at regular intervals along the trellis some twelve months before planting the Ivy. Rake the ground well, mulch with dung, and water well in dry weather, so that the climbers are encouraged to make a free growth. They will then run up to the top of the trellis, and may then be allowed free development. The Ivy will clothe all the lower portion of the trellis, and the climbers will keep possession of the higher part, and will bloom freely at their appointed time, thus affording a pleasing contrast.—J. C.

3773.—**Cropping a Garden.**—The following are among the best plants for producing cut flowers : Roses, Carnations, Picotees, Pinks, Pyrethrums, Delphiniums, Sweet Williams, Wallflowers, Stocks, double Zinnias, Asters, Paris Daisies, Anemones, English Iris, Astilbe japonica, Chinese Pinks, Phloxes, Lilium candidum, Geraniums, &c. As regards the vegetable portion, the only chance of making much profit is to have things early or late ; thus early Radishes, Lettuces, Potatoes, Rhubarb, Asparagus, Cauliflowers, &c., will be cleared off easily, but the midseason things when everybody has them will be a drug. Read the calendars carefully ; there's no royal road to knowledge. —E. H.

3742.—**Protecting Budded Roses.**—Procure sone Broom, and for dwarf Roses stick a few pieces in the soil all round the plant, and then bring the tops together and tie them firmly. The plants will have sufficient light and air, and be protected from the frost and cold winds. For standard Roses, fasten the thick ends of Broom tightly round the stock just below the buds, and tie the tops together. Such is the way I protect mine and seldom lose one, although only half-a-mile from the sea, and have very cold winds to contend with, which I find causes more mischief to the young shoots than frost.—H. E. B.

3771.—**Anemones.**—If Anemones are set a couple of inches deep, they do very well ; but there should be two plantings of them—one in November and the other in February. The finest flowers are generally produced the first spring after a new sowing. This will prolong their blooming season in spring, and by planting or sowing at different seasons they may be had in flower nearly all the year round. Both double and single require a light, rich, loamy soil, with a mixture of sea-sand. If sea-sand is not to hand, silver sand and some salt sprinkled with it will answer the purpose very well.—Bill-o'-the-Wisp.

3761.—**Hyacinthus candicans.**—I have kept this for three seasons in winter in sand in a pot successfully. It is said to be perfectly hardy.

3768.—**Spent Dyewoods.**—These are of no value for plants ; they might do to form drainage for bulbs and plants used some inches deep at bottom of trench.—W. B.

3766.—**Preventing Tree Stumps from Growing.**—To destroy the vitality of tree stumps is very difficult, as when the upper portion is killed they will often break out below. I once killed a number in this way ; I smeared them thickly with gas tar, and set fire to the tar ; the heat destroyed all the latent buds.—E. H.

—— Bore a hole in the heart with a large-sized auger, and insert an ounce or two of vitriol ; then cover with a small piece of slate and turf ; or if there are no trees near a heavy dressing of coarse salt will answer same purpose.—R. W.

3760.—**Forget-me-nots for Pot Culture.**—The best Forget-me-not for pot culture is dissitiflora. It should be grown thinly either from seeds or cuttings—with me the former plan does best—on a border in the open air till just before the flower-spikes push up, then potted, and brought forward in a cool, light, well-ventilated house or pit. Strong plants potted now and placed in a well-ventilated cool pit will flower well in the greenhouse or window in early spring.—E.

3761.—**Wintering Hyacinthus candicans.**—As the plants have grown so strongly, it would be a pity to take them up. This plant is hardy in light warm soils, but you may ensure its safety by covering the crowns with ashes, placing them in the form of a mound, so that they will throw off heavy rains.

3774.—**Passiflora cœrulea.**—Prune it back to about three-fourths of its length, and in the spring, just when growth is commencing, shift it into the next sized pot, unless the soil does not appear to be full of roots, in which case a top-dressing of concentrated manure will suffice. Loam, leaf-mould, and a little peat is the best soil. Give plenty of air in the summer.

3770.—**Anemones.**—Anemones are easily cultivated, and may be planted any time in open weather during the autumn and winter months, but as a rule the sooner they are planted after November the better. Plant 3 in. deep and about 5 in. apart. Keep the surface of the bed stirred when the young foliage appear, and look sharp after snails, &c.—E. H.

3767.—**Unfruitful Walnut and Mulberry Trees.**—Neither Walnut nor Mulberry trees bear well in a young state. They seldom bear much before they are twenty years old. Pruning their roots a little will probably throw them into bearing ; just cutting off their extremities on two sides will suffice.—H.

3699.—**Constructing a Fernery.**—In constructing a Fernery, I should advise "R. W. G." to be very liberal in the use of rough blocks of sand, stone, burrs, &c. Let it appear as natural as possible, and not as if done for effect. Wish regard to the cement and its colour, I should advise him to mix it with some red ochre for bricks, and for stone red ochre and lamp black, so as to have the cement to match the brick or stone, as the case may be. I have done so with very fine effect.—Bill-o'-the Wisp.

3642.—**Draining a Garden.**—Sink a shaft in the centre of your piece of ground, about 5 ft. or 6 ft. in diameter, and 6 ft. or 8 ft. deep, or till you come to sand, gravel, or some stratum that will absorb moisture ; fill the shaft with sound or broken pipes to within 4 ft., of the surface of the ground, then make your drains with 4 in. drain pipes from every direction to fall towards the shaft, letting all the shafts meet on the centre of the broken shreds. Then level your garden, but if your soil should be stiff clay you will require a copious admixture of brick rubbish or fine gravel worked into it in order to avoid the surface water.—J. Winter Wood.

3845.—**Moving Bulbs, &c.**—I have my garden planted with a miscellaneous lot of bulbs, such as Snowdrops, Anemones, Tulips, Winter Aconites, Tritonias, Scillas, &c. I am going to move in about January or early part of February. Will these bulbs stand moving ? if so, would it be advisable to take them up with a ball of soil to each, or detached from the soil ? Also, will it hurt perennials to move them so early in the spring ? I have also Pæonies and Rose trees I wish to take with me. —Thos. Percival. [All the above may be moved with safety at the time stated provided the weather is open. Of course, the more soil you can get with the roots the better, but this is not of so much importance as carefully avoiding breaking the roots.]

3846.—**Gooseberries for Exhibition.**—*A Cottager.* —The following are the best kinds of Gooseberries for exhibition : Reds—London, Dan's Mistake, and Clayton. Yellows—Leveller, Drill, and Catherine. Greens—Stockwell, Telegraph, and Shiner. Whites—Antagonist, Careless, and Hero of the Nile.

3847.—**Oxalis rosea and O. rosea floribunda.**—*W. B.*—These are very similar ; floribunda is a slight improvement on the type.

3848.—**Dividing Orchids.**—*L. L., Peckham.*—Cypripedium insigne should be divided in spring after flowering if you wish to increase your stock.

3849.—**Lilium umbellatum.**—*Aston Cross.*—This may be grown either in pots or the open ground. It likes light sandy loam or peat, but it will grow in any ordinary good garden mould.

3850.—**Watering Ferns**—Should deciduous Ferns be kept moist, or allowed to remain absolutely dry through the winter ?—R. C. C. [Keep the soil moist, but not wet.]

4851.—**Monkshood.**—In looking over a list of plants for a mixed border, given in Gardening, Oct. 9, I find amongst the list Aconitum, or Monkshood, and thought it would be of service to some of your readers to know that it is a deadly poison. I think it would also be advisable to make it known if there are any other poisonous plants in the list, so that they could be left out if any one was intending to grow them if they could not be grown with safety.—W. W. G. [It is advisable oftentimes to exclude berry-bearing plants of a poisonous nature from gardens to which children have access, but we do not see why poisonous-rooted plants should be omitted. Of course, if Monkshood is planted in the Horseradish bed bad results might follow, but we have never heard of any one being poisoned by eating the flowers they grow to look at.]

3852.—**Wintering Sparaxis.**—I sent for a dozen Sparaxis bulbs as an experiment this year (as Ixias succeed well in my little garden), and planted them with my other bulbs. Now I find I should have kept them till February, and they are already 3 in. or 4 in. high green and flourishing. What can I do to save them ? Will protection from frost be enough ? or must I pot them and take them in ? I have no greenhouse.—Junia. [Put a mat over them during severe frost, but do not keep them covered up only when absolutely necessary ; a glass frame is the best.]

3853.—**Rhubarb, Gooseberries, and Asparagus.**—*Pitman.*—Plant Rhubarb at any time from September to March. If a large growing sort, you must allow quite 4 ft. from plant to plant, but if a small sort 3 ft. will be plenty. Gooseberry trees may be planted 2½ ft. or 3 ft. apart each way. When they get too big, each alternate one may be removed. Asparagus is best planted in March.

3854.—**Moving Holly Hedge.**—*J. L.*—A Holly hedge which has only been planted two years may be removed with safety at any time from September till

April if the weather is open. Deep sandy soil well enriched with manure suits the Holly best.

3855.—**Radstock Beauty and Blanchard Potatoes.**—*W. J. K.*—There ought to be no difficulty in distinguishing Radstock Beauty from Blanchard, although both are flattish-round and similar in shape. Radstock Beauty is less depressed at the eye end of the tuber, and the blotching is a bright reddish-carmine. When cooked the flesh is yellowish-white and of first-rate table quality. The haulm is spreading, and the stalk paler than is that of Blanchard. This latter has very distinctive purple markings, and may easily now be distinguished, because tubers that have once been exposed to the light will show a purple hue all over, and it is not often that it can be exhibited twice for this reason, whilst Radstock Beauty keeps fresh for a long time. The two best mottled rounds are these you have; the two handsomest and best red rounds are Triumph and Grampian; the two best purple rounds, Vicar of Laleham and Scotch Blue; the best white rounds, Schoolmaster and Porter's Excelsior. Thus you get light rounds that will be found in every prize collection, and taking prizes everywhere at single dishes. At Birmingham Cattle show, Grampian and the Vicar of Laleham were the best coloured rounds, and Porter's Excelsior and Schoolmaster the best whites. Dividing Kidneys in the same way, the best two whites are Woodstock Kidney and International; the best reds are Mr. Bresee and Garibaldi; the best purples, American Purple and Purple Ashleaf; and the best mottled kinds, Heather Bell and Baron's Perfection.—A. D.

3856.—**Manure Water.**—I shall be glad to know whether a bushel of the manure is the correct quantity to use to 12 gallons of water for making liquid manure? I wish to use it for Pelargoniums, Fuchsias, Calceolarias, and other ordinary greenhouse plants when necessary. The above quantities are given in the first volume of GARDENING, but the proportion of manure seems so enormous for the water, that I have never ventured to use it.—E. E. K. [At first put have liquid manure and half clear water, and gradually increase the strength as the plants gain vigour. The tub must be filled up from time to time.]

3857.—**Pyrethrums.**—*J. B. S.*—These are best planted in September; you had better now wait till March. There are hundreds of spring-flowering plants, and you do not say what kind of plants you need.

3858.—**Treatment of Musk.**—*Amateur.*—Musk is a perennial, although it may be used as an annual by sowing seed every spring. If you take up the roots in spring and divide them, you can increase your stock to any extent.

3859.—**Pruning Moss Roses.**—*J. N.*—Cut out most of the old wood close to the ground, and also remove any weakly young shoots, and slightly shorten back any that are long and straggling. Prune now.

3860.—**Exposing Manure to the Air.**—*E.*—If the manure is covered with soil, the ammonia will not be so likely to escape, but there is no advantage in burying manure in a pit, as it cannot be conveniently turned when necessary.

3861.—**Culture of Cyprus Grass.**—*E.*—If you mean Cyperus alternifolius, use rich turfy loam and leafmould with plenty of sand added. Place in a temperature of 50° to 60°, and give plenty of water.

Names of Plants.—*We cannot undertake to name what are termed florists' flowers, which include Pelargoniums, Fuchsias, Roses, Chrysanthemums, &c. These can only be named by specialists who have the means of comparison at hand.*——*Novice.*—1, Phyllocactus (species); 3, Echeveria metallica; 5, Kalosanthes coccinea; 6, Sedum carneum variegatum; 7, Coronilla glauca; 8, Saxifraga sarmentosa; 9, Sedum Sieboldi.——*N. M. R.*—New Hawthornden.——*Mrs. D. Eaton.*—1, Schezœa dichotoma.——*W. W. B.*—Hairy Crowfoot (Ranunculus hirsutus); dig out the roots whilst the ground is soft.——*W. W.*—Eribotrya japonica, the Loquat or Japanese Medlar.——*E. M. R.*—Eupatorium of some kind.

QUERIES.

3862.—**Hedge for Garden.**—The west side of my garden is bare. What sort of hedge can I plant on the bank near a pond that would soon grow and keep off the boisterous west winds. Some of my friends recommend Willow, but would not that be rather unsightly?—PITMAN.

3863.—**Vegetables for Exhibition.**—Will some experienced reader inform me what are the best kinds of vegetables for competition, viz.:—Celery, Onions, Leeks, Beet, Turnip, early and late Carrot, Rhubarb, Greens, early and late Cabbage, Savoy, Cauliflower, Parsnip?—W. B.

3864.—**Covering a Vine Border.**—Our man having heard me read the article in GARDENING ILLUSTRATED on "How to make and plant a Vine border," thought he would thatch our border, which is outside, and the Vines, which are about ten years old and taken through the brickwork, are bearing a fair crop and nearly ripe, yet the foliage was green. Instead of using dry straw he put a coating of about 1 ft. thick of hot long stable manure, the ground being frozen hard at the time. The result is that all the leaves of the Vines were scorched up in one day, and the fruit begins to look shrivelled. Can any one tell the reason? House heated with hot water, kept to between 60° to 70°. What must we do with the Grapes?—EDITH.

3865.—**Iris Kæmpferi.**—Does this require any special protection when planted a month ago? and will good rooted plants blossom next year?—W. B.

3866.—**Romneya Coulteri.**—Can any one enlighten me on the culture of this plant?—W. B.

3867.—**Malformed Chrysanthemum Flowers.**—I shall be obliged if any one will inform me the reason of my Chrysanthemum flowers being small and malformed. In some cases the malformed blooms are the centre ones on a branch, and in other cases there are very good blooms on the same plant. Manure water was regularly administered until the plants showed colour. I have done a fair amount of disbudding.—F. J.

3868.—**Mulberry Tree not Fruiting.**—There is a Mulberry tree in my garden which I have never seen showing any bloom or bearing any fruit; it is thirty or thirty-five years old, and looks in a healthy condition; it is the only tree of the sort in the garden, and was transplanted about ten years ago. Any advice about it will much oblige.—O. V. J.

3869.—**Raising Seeds.**—I have received a packet of seeds from Sydney containing Clianthus Dampieri, Kennedya rubicunda, Swainsonia coccinea, Cape Broom, Eucalyptus (Blue Gum). Having a cool greenhouse, I would be glad to know if these seeds could be successfully brought on without bottom-heat; and if so, at what time they may be sown, and in what soil.—SUBSCRIBER.

3870.—**Tomatoes under Glass.**—Referring to a most useful article on the Tomato by "H. H." (p. 437, GARDENING ILLUSTRATED, November 13), will that gentleman still further oblige by saying if the top of his Peach house is covered with trees? I once tried Tomatoes on the back wall of a Vinery and they were a complete failure; I suppose in consequence of the shade. Will "H. H." also say if he pinches the shoots as is usually recommended? If so, how does he get such large plants 70 or 80 sq. ft.? I have nearly fifty fine plants here this year against a south wall, and gathered about two dozen fruit.—F. S.

3871.—**Violets in Winter.**—Is it natural for Violets carefully planted as recommended in an article in GARDENING, November 27, to lose their leaves during the recent frosts when planted out-of-doors? Will they, if thoroughly protected with fine ashes, send out fresh leaves and flower in the spring? What description of Violet will stand out-of-doors a winter like our last one?—PANSY.

3872.—**Roses not Flowering.**—I have several large Gloire de Bordeaux Rose trees which make an immense amount of wood and foliage, but produce no Roses. Can any reader inform me what is best to do to produce plenty of Roses and not so much wood and foliage?—J. LACEY.

3873.—**Holes for Fruit Trees.**—I have planted 200 Apple, Pear, and Plum trees in an old orchard, the soil of which is good fibry loam. The holes were dug about 2 ft. 6 in. across and 1 ft. 6 in. deep, the bottom dug up and mixed with good rotten manure. The orchard lies dry. I am told by a friend I shall lose all my trees, because I have not dug the holes 5 ft. across. Will some one oblige me with their opinion on the subject?—A. S. V. P.

3874.—**Pruning and Training Vine.**—I have recently purchased a Black Hamburgh Vine; it is what is called a fruiting cane, and consists of a single rod about 8 ft. long. I have planted it outside a small unheated, lean-to house (8 ft. 6 in. by 5 ft. and 6 ft. high in front). It is drawn through under the sill, and I intend training it under the roof. Being an entire novice in the art of Vine growing, I should be obliged if some reader of GARDENING will kindly instruct me how to proceed in the matter of pruning and training.—J. G. SMITH.

3875.—**Foxgloves.**—Having transplanted June-sown seedling Foxgloves about two months since, so as to procure a show next season, I should be glad to know if they are likely to survive the winter, as the late rains and frosts have entirely blackened and partially destroyed the foliage, and what were fine healthy plants a short time since are now wretched objects. They are planted in a broad bed facing south-west in ordinary black garden mould in which such subjects as Gladioli, Japanese Maize, &c., do well.—S. H. G.

3876.—**Insects Eating Ferns.**—The young fronds of my Maiden-hair Ferns appear to be bitten off by an insect as soon as they come up. Can any one kindly tell me how I should treat them? they appear to be in good health, and I cannot discover any insects about them.—F. C. H.

3877.—**Old Roses.**—Can any one inform me where I can obtain some plants of old Roses, such as Alba moschata, Austrian Brier, villosa, &c.?—S. E.

3878.—**Camellias from Cuttings.**—Should these be placed in an ordinary pit with heat? Should they be cut down to two or three joints, or be taken from the main stem? Notes on the above by some experienced contributor would no doubt prove beneficial to many.—AMATEUR.

3879.—**Pruning of Rosa rugosa** (old Macartney Rose).—Will any reader inform me when and how to prune a strong-growing plant (small bush) of this in the open border? also, where I can get a strong plant of the white variety? It seems to be scarce.—H. S. L.

3880.—**Lilium giganteum and Lilium Washingtonianum.**—I have failed with both of these fine Lilies. Will any one who has been more fortunate favour me with practical directions for their culture? Is not their alleged hardiness (unless in favoured localities) a myth?—H. S. L.

3881.—**Unfruitful Cherry Tree.**—I have a large White Heart Cherry tree which does not bear any fruit. It seems healthy, but the spurs die away every year. It is a very fine tree, and it is trained to a west wall, and here we do not get such severe winters as in England. I should be glad to know the cause of its unfruitfulness and the remedy.—H. G., *Guernsey*.

3882.—**Keeping Frost from Evergreens.**—Will some reader of GARDENING kindly give me instruction how to protect from frost my Laurels and Bay trees, as I had several cut down with frost last winter and some killed; they are from 3 ft. to 8 ft. high; the soil is wet and heavy.—F. C.

3883.—**Lilies and Forget-me-nots.**—I have had great pleasure from following a plan, often recommended in GARDENING ILLUSTRATED, of growing bulbs in a bed carpeted with low-growing plants, and have been very successful with Tulips and Silene pendula. I want to plant Lilies in a bed of Myosotis dissitiflora. Will not the yearly replanting which I am told is desirable for the Myosotis be very injurious in disturbing the Lilies? Can this difficulty be overcome?

3884.—**Draining a Garden.**—I lately formed a garden on what had previously been a bit of waste ground, 25 yds. by 18 yds., well sheltered by buildings from north, east, and even south winds, but bounded on the west side (25 yds.) by an old pool 10 ft. deep, which stretched from one end to the other. As the old piece of ground was only a few inches above the water, I had a very large amount of good soil hauled on to it, raising it to about 22 in. above the surface of the pool, and have had some good crops from it this summer. It, however, wants draining. Is 22 in. not deep enough, so that I could drain it into the pool? Or, if I made a blind well in the middle of he garden and drained into that, would not the water from the pool (9 yds. off) percolate and enter the well?—PITMAN

3885.—**Pruning Climbing Roses.**—I have several climbing Roses which I wish to train on walls and pillars; they were planted last year and during last summer, and have made considerable growth, some of the shoots being 6 ft. long. The late frosts have in some cases nipped the ends of the shoots. Should I prune them? if so, to what extent and when should I do so?—A. W.S.

3886.—**Plants for Hanging Baskets.**—Will any one give me a list of Ferns and plants most suitable for hanging baskets for spring, summer, autumn, and winter?—R. W. W., *Belfast*.

AQUARIA.

FISH DYING IN AQUARIUMS.

I DO not gather from "A New Reader's" circumstantial account of his aquarium, p. 458, that he has fulfilled the first requisite in its arrangement—viz., growing plants. If he had supplied these, instead of daily changing the water, which need only be done once in six months, he would have had better results, as plants, fish, and mollusca supply all the essentials of healthy life in an aquarium—each giving out what the other lacks, the snails acting as scavengers, clearing off the superfluous growth of vegetable matter.

In the artificial state in which "A New Reader" keeps his fish it is impossible to ensure healthy life, as, although a daily change of water may be refreshing to the fish, it is a spasmodic and unnatural excitement, which cannot contribute to longevity.

It is perfectly useless to "throw in a handful of weeds or watercress." Your correspondent might just as well throw on his flower-bed a handful of daisies and marigolds and call it a flower garden! Water plants, like any other plants, require planting in the sand or gravel forming the bed of the tank, when they will grow luxuriantly, simply requiring cutting occasionally to keep them within bounds. I have kept gold fish for years in conjunction with water plants, only changing the water when the plants and rockwork require rearrangement.

From my experience, fish do not need much feeding, although I sometimes gave my fish, by way of treat, a few bloodworms or pieces of raw beef cut very small. Vermicelli is unobjectionable, except that it tinges the water with a milkiness, but bread should never be given to fish, as it is very injurious.

I should be sorry to "paint" my fish with bichloride of mercury, or any other chemical. If I did I should not be at all surprised at their remaining dormant for a fortnight or any other period. When gold fish become furred with fungus or slime the simple remedy is to place them in a shallow vessel of water and throw a handful of silver sand on them, when their own efforts to rid themselves of this will at the same time remove the fungus.

I should recommend "New Reader" to place at the bottom of his aquarium a layer 2 in. deep of well-washed shingle, or coarse sand, and plant Vallisneria spiralis, Chara vulgaris, or Myriophyllum spicatum. The common Anacharis is very pretty, but it grows so rapidly that it requires constant pruning, and therefore a very small quantity will suffice. I should allow on an average one water plant to two fish. In planting it is well to tie the ends of the plant to a stone, burying it in the shingle, otherwise they are apt to get loose and float to the top. It is not necessary for the plants to have roots, as most water plants rapidly strike root when placed in sand or gravel, and they can be divided *ad infinitum*. A few small eels, about 3 in. long, which can be purchased in London for a penny each, will be found a lively and interesting addition to an aquarium.—FRANCOIS, *Enfield*.

To Preserve Eggs.—One pound of quick lime, one pound of salt, three ounces of saltpetre, one gallon of water. Boil fifteen minutes, put it into a crock or vessel lined with lead; when cold put the eggs in, place in a cold cellar, and they will keep twelve months.—J. INGALL.

HARDY WINTER FLOWERS—CHRISTMAS ROSES AND SNOWDROPS.

HARDY WINTER FLOWERS.

If there be a dull dreary month in the year it is that of December, when Nature may be said to rest and recruit her all but exhausted energies, and prepare for a fresh start with the returning sunshine of the youthful year upon which she is so shortly to enter. But however dull and cheerless it may be, we cannot but look upon it as any other than a wise arrangement that there should be these breaks in the continuity of the floral year. The depth of the valley contributes in no small degree to the apparent height of the mountain; and so with us the winter's rest of Nature—which, possibly, we may have altogether forgotten—enables us to value fully the budding beauties of spring, the brighter glories of summer, and the beautiful flush that pervades all Nature in the autumn, betokening, as it does, even in its loveliness, both death and decay. I have alluded to a break in Flora's wreath, but does such really exist? I admit that the wreath becomes slender, yet, if we search well, there are some links to be found whereby its continuity may be preserved, and it is my object here to point out where those links may be found, each one of which has a value far beyond that of the brightest gems of summer—they are like oases in the desert, few and far between; but on that very account all the more precious. I have often been struck with the marked peculiarity that many of our Japanese and Chinese plants present, as regards their time of blooming. Who, that has contemplated the bright golden blossoms of the Jasminum nudiflorum produced throughout December, January, and February, without any intermission beyond that occasioned by severe frost, but must have been struck by the strangely unseasonable time and method of its

blooming? Again, the Chimonanthus, in its fragrant, large-flowered and other varieties, if they lack in brightness of colour, certainly acquire ample compensation in the delicious perfume their flowers possess—these may be reckoned as links in the December chain. Again, our more familiar Chrysanthemums are of similar origin, and I am sure none will deny their value, or the important place they claim in the floral wreath. Still further, we have Saxifraga Fortunei, a winter species amongst a host of spring-flowering congeners. Cydonia japonica and Forsythia viridissima are amongst our early spring flowers, and both claim an extreme Eastern origin. Is it that the Chinese have, with their horticultural skill, exercised for centuries, been enabled to influence them to such an extent that, as regards the period of their flowering, the plants have become moulded, as it were, to their whim and fancy; and that even when imported into this country they retain their foreign peculiarities of blooming intact? These questions have suggested themselves to me, and without attempting a reply, I leave it to your readers to form their own opinion, contenting myself by saying, that to China and Japan we are

Common Christmas Rose.

indebted for some of our very best December flowering plants—plants that appear to belong, florally speaking, to the darkest and dreariest months of the year—an inherited peculiarity for which, come how it may, we have reason to be thankful.

From Southern Europe, we have in the Arbutus and Laurustinus a brace of plants, whose value for winter-blooming it would be difficult to overrate, the more so as, associated with the beauty of the blossoms, there is, in brilliant rivalry, the beauty of the fruit; in the one case, we have pendent crimson globes, deep coloured, bright crimson or yellow, according to their degrees of ripeness, hanging beneath the lovely wax-like blossoms, which seem to unite, associated with the bright green leaves, in one tree a mass of beauty; in the other, we have not unfrequently, along with the ample expanse of rosy-white blossoms, the deep metallic blue fruit of the previous season. This is especially marked in the more rigid form of the Laurustinus.

We have also one of the most graceful plants in Garrya elliptica, whose pendent spikes of bloom, simple as they may be, constitute an element of decoration that has few equals out-of-doors in the month of December. This is a contribution from the New World, and one that is doubly welcome, not only for its flowers, but for its evergreen and, comparatively speaking, hardy character.

Amongst fruits, the bright glistening scarlet berries of the Holly, and the pearl-drops which bedeck the Mistletoe, are so familiar, and so happy in their associations, that their mere mention will suffice; nor must we omit the Pyracantha, whose gorgeous and massive clusters of Orange-coloured berries, if protected from the attacks of birds, will retain their beauty far into the New Year. Our old friend, the Aucuba, with which many are familiar under the title of the Variegated Laurel, after the introduction of the male variety, promised to be one of our most prolific and important berry-bearing plants; but though years have elapsed since then, it is rare to see a plant out-of-doors whose berries have been successfully fertilised.

Dwarfer in stature, and less general in cultivation, are the Pernettyas; in P. mucronata, when planted in a sheltered and sun-exposed

Purple Christmas Rose.

position on the rockery, the deep crimson berries are freely produced, and contrast beautifully with the dark green foliage; in P. candida, a more recent introduction, and quite dwarf in habit, we have charming pearly-white fruit, suffused with a rosy tint, in happy association with which might be named the North American Gaultheria procumbens, whose highly-tinted leaves all but rival in colour the scarlet berries which peep from their clustered masses.

If there is one flower more than another to which the title of "December's glory" might rightly be applied it is the Christmas Rose—the Helleborus niger—and most especially is it applicable to that form well named grandiflorus, and sometimes called the Scotch variety. The flowers are produced in twos or threes on stout, erect stems fully 8 in. long; they are 4 in. across at least, and, rising well above the soil, in addition to the natural protection afforded by the autumnal leaves lying on the surface of the ground, the broad expanded cups of lovely whiteness remain unsullied by even a speck of the closely adjacent soil. I ought to mention that the flowers do not all expand at one time, but follow each other in rotation. The foot-stalk is of a lovely marbled-pink colour, which colour, by the way, expands in gradually softening tints over the entire upper portion of the sepals, giving to the flower, as viewed externally, a charmingly delicate roseate hue that is never met with in the old species. Though I have written thus

Winter Heliotrope (Tussilago fragrans).

enthusiastically about this variety, I do not for one moment wish to disparage the old species itself; though blooming a little later, it still comes, and comes naturally, at a time when it has scarcely a rival. It is one of the few legitimate December-flowering plants that is able to stand all sorts of weather. Helleborus atrorubens and purpurascens, in mild seasons or in sheltered localities, may be sometimes reckoned as December flowers, but their claim to this title, like those of others I shall have now to name, hinges much upon the very uncertain conditions of season and weather.

On the one hand, a mild protracted autumn extends the blooming period of some plants even to Christmas, and the very same conditions excite another set into premature activity; while a month or six weeks of frost and snow, which we in the north, at least, sometimes experience, suspends active life altogether, and when this occurs, you may rely upon it that the first comers of the new year will have much the advantage over the latest-blooming varieties of that which has passed away. Thus our December flowers naturally group themselves accordingly—as mementoes of the past on the one hand, and as hopeful harbingers of the future on the other.

Amongst the former we have the tall Aster grandiflorus and the dwarf Asters Reevsi and versicolor; latest of all, the Michaelmas Daisies, still gay after their respective fashions. The ever-flowering Vittadenia trilobata—lovely with its simple Daisy-like flowers—the Rock Speedwell (Veronica rupestris), whose dense dwarf tufts are rarely seen undecorated by a few spikes of its deep amethyst-blue flowers. The summer-blooming Gentiana acaulis, rich in its cobalt tint, under favourable conditions, not unfrequently bids an adieu to the parting year, and makes, so to speak, an acquaintance with his vernal relation G. verna, whose flowers, if smaller, are more intensely blue. Somewhat similarly related are the Cyclamens, the late-blooming C. europæum having scarcely cast its flowers ere it is succeeded by the small bright crimson blooms of C. coum; more appropriate

Winter Aconite (Eranthis hyemalis).

and lovely plants for a sunny nook at the foot of a rockery—their pretty mottled leaves rising in over-lapping masses above the surface of the Grass—cannot, it will readily be admitted, be found.

The Japanese Honeysuckle (Lonicera japonica), when allowed to ramble unrestrainedly, not unfrequently yields a few sweet-scented blooms even thus late in the season, sufficient to render it worthy of mention as one of our December flowers. Too often under the restricted conditions of wall culture, where we generally meet with this plant, its autumnal display is sacrificed to neatness and tidiness as regards the appearance of the conservative wall. Under the same conditions we sometimes meet with Clematis cirrhosa, its blooms suffering from a similarly restrictive policy. Where free development is allowed, such as is possible on a sunny slope formed of old roots, among which these creepers will find ample support, not only does their true autumn-blooming character become perfected, but the possibility of an addendum of winter flowers is also secured.

Schizostylis coccinea, an Iridaceous plant of great beauty, from the Cape, when well managed produces its flowers throughout the whole month. They are borne on slender stems about 12 in. high, have the aspect of a Gladiolus, and are bright crimson in colour; the plant is perfectly hardy. Why, then, do we so often find it represented by a large patch of grassy foliage with possibly only a solitary flower-spike. The reason is, that amid the myriads of offsets it produces, none of them come to maturity. Were the tuft divided in spring, and the strongest planted separately on the sunny south wall border of a garden, 6 in. apart in the row, in light soil, and a little care and attention given the months of November and December would find each individual tuft producing two or three spikes of lovely flowers, that remind one of the peculiar tint of crimson we have in the Linum grandiflorum, alike valuable for cutting as for

the general decoration of the garden. When thus planted, in the event of a severe frost setting in, a movable frame might readily be placed over them for protection.

Mentioning the frame reminds me that there is a great similarity between the culture I have recommended for this plant and that at present adopted for winter-blooming Violets, whose right to rank amongst the sweetest of our December flowers no one will deny.

Amongst the Tritomas we have some of the less highly-coloured varieties that are strongly endowed with winter-blooming proclivities.

The Primulas, both double and single, in the Primrose, as well as in the Polyanthus form, give us a few blooms in November and December. Nor is it unusual to see the spring time anticipated, as it were, by scattered flowers here and there on our Alpine Auriculas. This is more especially the case with seedlings which have been planted out in early spring. These autumn flowers appear to act as a sort of safety-valve, whereby the plants are enabled to throw off their superabundant vigour. The winter-flowering Violas or Pansies were, in olden time, few and far between, but they are now more numerous. The white, crimson, and intermediate forms of the double Daisy, including as well those with golden mottled leaves, often anticipate their spring glory by a few mid-winter blooms sufficient to claim recognition.

In favoured localities, amongst the advance guards of spring, we find the Winter Aconite (Eranthus hyemalis) peering out from its sheltered home beneath the leaves to give welcome to the Christmas morn. So also the Bulbocodium vernum, whose similarity of bloom, both in style and colour, at once attests its close relationship to the Autumn Crocuses, or Meadow Saffrons, as they are called. The Gladwin (Iris fœtidissima) long known to lovers of hardy flowers as a bright-fruited native plant, has lately become popular in Covent Garden, where piles of its curious fruit may now be seen.

Amongst trees I may mention the Japanese Witch Hazel (Corylopsis spicata), whose large-flowered pendent catkins are freely produced fully two months in advance of our common Hazel. I had almost forgotten my special favourite the fragrant Coltsfoot (Tussilago fragrans), or, as it is sometimes called, the Winter Heliotrope, a very happy name, originating in its delicious perfume, which appears to combine those of the Heliotrope and Hawthorn, produced by the most modest and unpretentious of grey flowers. In growth it is a vagabond, but is well worthy of a good corner in some plantation, where it may gratify its rambling propensities unrestrained, as, under those conditions, it produces its flowers in greatest abundance.

I have purposely omitted here many plants which, in the extreme south of England and Ireland, may be found in bloom in December; we must look upon these localities as exceptionally favoured. I am fully aware that there are places where material might be found to treble the list I have given; but for one person that rejoices in such happy conditions, there are ten who have to battle with Nature under more disadvantageous circumstances, and to such I must be considered as addressing myself. I trust I may be found to have fairly established the claim for dull December with which I started—that even it can boast of its Christmas Rose of greatest beauty, and can, and does, contribute at least a few gems well worthy of a place in Flora's diadem. J. C. N.

Cheap Basket for Ferns, &c.—Few baskets can be made more quickly or cheaply than those formed of virgin cork. Suitable pieces, cut in equal lengths, can easily be made into a round basket by means of strong wire, and a bottom may be fixed in a like manner. Club Mosses and Ficus minima grow readily on cork, and an elegant green basket can thus be obtained, which, if filled with Orchids, Ferns, or similar plants when suspended from the roof, has a fine appearance.—S.

Peat as an Antiseptic.—It seems to me to be a great pity that so many bulbs should rot every year when such a catastrophe may be so easily averted by using peat with the compost. The antiseptic qualities of peat are of course well known, and a handful mixed with a 5-in. potful of the compost in which the bulbs are planted would save many a fine bulb, which is otherwise lost. I pursue this plan myself, and in the case of Roman Hyacinths, which are so very subject to decay, especially I consider peat to be a most valuable adjunct to the compost.—Girofle.

TOWN GARDENING.

Cineraria maritima and candidissima.

This plant is very useful for the flower garden. It seems to do better in town air than any other white or silver-leaved plant, though the elegant Centaurea will do fairly, with care. It should be treated as an annual—*i.e.*, sown early in spring, in boxes of light soil, pricked off, and planted out at the end of May. There is no necessity to pot these plants, and a very gentle heat just to germinate the seed, and while the plants are young, is sufficient. It is a strong

Cineraria maritima in flower.

rooting plant, and likes rather a loamy soil, more so than the Golden Feather, or Pyrethrum, which requires similar treatment. Old plants are much whiter in the hue of the foliage than young ones, but as the winter always kills these, the only way to keep them is to pot carefully, and give the protection of a cool greenhouse, or a well-protected cold frame. But it is hardly possible to find room for many plants in such places; however, a few may be tried, as a fine old plant makes the best possible centre for a bed of scarlet geraniums. The variety candidissima is much more effective than the type.

Dahlias.

The Dahlia is so easily grown, and blooms so well even in densely-populated towns, that if there is room a few plants should always be grown. They look especially well at the back of a mixed border of flowers, but they do best in open beds.

Culture.—This is very simple. Procure as many young plants as you require about the end of May; good named varieties (spring-struck cuttings) can be purchased for 3s. or 4s. per dozen. They are usually in small 3-in. pots, and are quite as good as older plants for ordinary purposes. Dig the ground for them deeply and well, working a quantity of manure especially at the bottom, and when settled set the plants in their places, pressing the soil firmly round them, and tie each one to a small stake, as they are easily broken by wind. They should have a sunny position, and beyond replacing the small stake by one 3 ft. or 4 ft. long when the plants get large enough to need it, and giving a good soaking of water and liquid manure occasionally, in dry weather, they will need but little attention. There is seldom any need to pinch out the tops, as most of the varieties will branch out quite naturally if in an open and airy situation. They should be frequently syringed overhead, or have a good shower from a watering-pot to keep the foliage clean. Always prefer the syringe if you have one, as the water is driven more forcibly against the surface of the plant, and this brings dirt and dust off more effectually. When the foliage has become dirty we find it a good plan to give the plants a gentle shower over in the evening when the sun has set, just to damp and loosen the dirt, and then come round again in a quarter or half an hour and give a thorough syringing to wash it off. The plants will produce numbers of beautiful flowers in August and September, and we have even cut good blossoms in November, not far from London Bridge.

Lifting and Storing.—As soon as the tops are cut down by frost, and the roots well ripened, but before the ground gets frozen, cut off the stems down to the ground; take up the roots carefully, so as not to injure the embyro roots round the collar of the plants, dry them gently for a few days, and then pack them in sand, light dry soil, or cocoa-nut fibre, in pots or boxes, and stow away in a cellar or other place where they will be safe from frost. They will hardly need any water through the winter, but must not get so dry as to shrivel.

Propagating.—In spring the old roots may be planted, as soon as all danger of frost is over, as they are, in which case they will make fine bushes, or each tuber may be taken off with an eye or two, potted, and started in a gentle heat. But the best way to increase the stock, if required to do so, is to remove the roots, just as they are in the pots or boxes, to a warm greenhouse in February or March, give a little water as they begin to grow, and as soon as the young shoots that spring up round the stem get 3 in. long take them off with a sharp knife, put each singly into 3-in. or 3½-in. pots, or four or five round a large one in very light and sandy soil, and place them in a gentle hot-bed of 65° or 70°, keeping close. Here they will readily strike root, when they may be hardened off and planted out as before directed. Where extra fine plants are required, shift them as soon as well rooted in the small pots to others 5 in. or 6 in. across, place in a cold frame early in May, and plant out from these.

Helichrysums (Everlasting Flowers).

These are so easily grown, so pretty, and the flowers when dried last so long, that we strongly recommend them. The double dwarf kinds, and especially a variety called "monstrosum," are by far the best; separate colours can be had if desired. Sow the seed in the first week in April, in equal parts of loam, leaf-mould, and sand, or any light, rich soil, but the compost of course gives the best plants. Cover the pans or boxes with glass, and place in a frame, with gentle heat, if possible, or a window or cold frame, or even a box out of doors covered with glass will do. When large enough prick out into boxes, or into nursery beds out of doors, and when good sturdy plants, three or four inches high, set out in their places. They may be planted either singly in

Everlasting Flower (Helichrysum bracteatum).

mixed borders, or will make a fine bed by themselves. We, however, generally put three in a group, triangularly, the plants about 6 in. or 8 in. apart. This makes a pretty group. Give them rich soil and plenty of water if you want fine flowers, yet few things will stand so much drought uninjured. For drying, cut the flowers when just opened, and hang up by the stalks, head downwards, in a sunny window; when thoroughly dry, store away for winter use, or make up into bouquets at once. A few dried Grasses, such as Stipa pennata (Feather Grass), Panicum virgatum and fimbriatum, Agrostis nebulosa, Briza gracilis, or others, mixed with them, are a great improvement, and if you have not sufficient variety of brilliancy of colour, use Judson's dyes to deepen or contrast them. It is almost needless to say that these dried grasses and flowers must not be placed in water; on the contrary, they must be kept as dry as possible.

Lobelias.

These are so useful for edgings, baskets, window-boxes, and almost numberless purposes of display, that they should be grown by everyone. Great difficulty will be experienced in

keeping these through a town winter, and the easiest and best way is to grow them fresh from seed each year.

Sowing.—Sow the seeds either in autumn or in January or February, as a great mistake is made by some people in sowing so late that they have to be forced rapidly on in heat; while, if they have plenty of time to grow in, they will do far better under cold treatment. Sow in pans or boxes, using a light soil of loam, leaf mould, and sand, in nearly equal parts—the top ¼ in. finely sifted. The seed will germinate in any ordinary greenhouse if a sheet of glass is placed over the box, or even a sitting-room window will do. If in a greenhouse the pan should be placed on a sunny shelf, and if a heat of about 60° can be afforded all the better; but the heat must not be continued too long.

Potting.—As soon as they are large enough to handle, or ½ in. to ¾ in. in height, prick off into boxes 1 in. or 1½ in. apart. Keep close, and a little heat would be advisable at this stage, to induce them to root well; then, when strong, either pot singly in small 60-sized pots, or take out every other one and transplant into other boxes or cold frames. Where a large quantity are needed it is advisable to prepare a frame by putting 2 in. or 3 in. of nice light rich soil in the bottom, with a little heating material underneath, just to give them a start, and prick out 2 in. or 3 in. apart into this from the seed-pan. From such beds or boxes they may be planted out where they are to flower, taking them up with good balls of earth, and planting about 6 in. apart in the row. This saves the bother of potting, which is not by any means necessary.

Raising in Windows.—For those who have no convenience of frames or greenhouse, sow the seed, covering with a sheet of glass, as above directed, and keep in the window of a kitchen or sitting-room, and when large enough prick out into boxes covered with glass out-of-doors. These are very useful in many ways. We find the Swiss milk cases, to be had at any oilman's or grocer's, a very useful size. They are about 20 in. by 14 in., so that two sheets of glass, 14 in. by 20 in., costing about 4d., will cover them nicely. Place them in a warm, sheltered, and sunny place, put 3 in. of broken bricks or ballast, or even ashes, at the bottom, on this an inch or two of spent hops, and fill up to 3 in. or 4 in. of the top with nice fine rich soil. Into this you can prick out Lobelias, Petunias, Verbenas, and many other things quite safely about the middle of April. Keep the glass on closely at first, and as the weather gets warmer, and your plants stronger, expose them more and more till the glass is dispensed with altogether. You have thus a month or six weeks for your things to grow in before planting out, and, being so close to the glass, they will be fine and strong. One of these boxes will contain enough plants to fill a moderate-sized flower-bed.

Marvel of Peru (Mirabilis jalapa).

This makes a well-shaped bush, and no situation is too hot and dry for it to grow in. Sow the seed in March in heat, or out of doors in May, and the plants will bloom the same summer. The old bulbs must be taken up when the stems die down at the approach of winter, and stored in a cellar or other dry place, safe from frost. Old plants that flowered early will frequently be found to have seedlings sprung up around them in the autumn, and if these are carefully taken up and stored away in a little earth they will make good plants for next year. Although they stand drought so well, yet, like all other plants, they will succeed better if planted in rich soil and kept fairly moist.

Mimulus (Monkey Flowers).

These should be treated precisely the same as Lobelias; give them plenty of water, and as little heat as possible. There are many named kinds now in commerce, but a packet of seed of a good strain will produce as good flowers as anyone can wish to see; these plants come very true to colour and shape, &c., from seed. They may be planted out about 6 in. apart in any open border in May. Sandy loam and a somewhat shaded situation suits them best, though they will do better in the full blaze of the sun than in a very shady or gloomy place. The soil need not be rich, and it is astonishing how little soil they will grow in, and, in fact, they flower far better when cramped at the root. About the best place for them is on rockwork, round a fountain in the sun, where they will have plenty of water, sun, and air, and but little earth to grow in.

Œnotheras (Evening Primroses).

There are several varieties of these, all of which are more or less adapted for town culture. The Œnothera grandiflora, or Lamarckiana, is, however, much the hardiest and most free-flowering. It is commonly known as the Evening Primrose. These plants have bright yellow flowers, which open in the evening, and it is very interesting to watch them expand, which they do quite suddenly, unfolding their petals in much the same way, and in about the same time, as one would open an umbrella. They grow from 3 ft. to 4 ft. in height, and seem to flourish equally well in a bed of rubbish, or on a dry rockery, as in deep rich loam. They are propagated by seed, which may be sown at almost any time—it is sure to come up. If sown early in spring, in the open border, it will bloom late in the autumn, but the plants that make the best display are seedlings of the last year, which will stand the winter out of doors, and come into bloom in July. They prefer a sunny situation.

Phlox Drummondi.

Petunias.

We think it a great pity that these showy plants are not more generally cultivated. One often meets with people, and people who are fond of their gardens too, who do not know what Petunias are. They would not think the garden complete without a bed of Verbenas, and though universally admired, when they are seen, no one seems to think of growing Petunias. Yet the flowers are of great size, a single bloom usually being larger than a whole truss of Verbenas, the colours are unequalled, the markings are found of almost unlimited variety, and the plants themselves are extremely easy to grow, and will often succeed well in soils totally unfit for Verbenas. A bed of mixed colours is extremely effective, and in this case seedlings may be used, and for general purposes these are preferable to plants from cuttings, as they are more easily grown and much more vigorous.

From Cuttings.—If separate colours must be had cuttings must be taken. Strike them early, in July or August, and label them carefully, as the effect of a bed is often lost through getting the varieties mixed up. They will strike easily in a cold frame, kept close. When rooted, pot off singly in 3½-in. pots. These should be kept through the winter in a light airy greenhouse, if possible, or in a sunny window of a warm room. Keep them slowly growing, if possible, and pinch out the tops, so as to have a nice lot of young shoots about 3 in. long by March, or whenever you can strike them. When your hot-bed is about 70°, and nice and sweet, take off the cuttings, trim them, and insert five or six round the sides of a 3 in. or 3½-in. pot, using loam, leaf-mould, and sand in equal parts; give them a sprinkle, then stand aside till dry, and place in the frame; give only a little air till struck, then increase the quantity, and when a little hardened pot off singly in 3-in. pots, using light loam with a little leaf-mould and sand. Keep close a few days, then harden off gradually; plant out the last week in May. Soil—almost anything will do, it need not be very rich, as the plants are robust growers generally. They do best in a light soil, and when well established need but little water at the root; though in towns it is advisable to give them a fair amount of manure, and also a good showering overhead morning and evening, to keep the foliage clean, and do not let them get very dry at the root. The plants may be either trained upright on sticks, pinched in so as to form a compact bush, or pegged down like Verbenas.

From Seed.—For mixed beds seedlings are best; get a packet of seed of a good strain, and sow either in September without heat, and prick off into store pots or boxes for the winter, or sow in a gentle heat in February or March, say 60° or 65°, or simply in the greenhouse; or a sunny window will do after the end of March, covering the pot or pan with a sheet of glass till the seedlings are up. Early sown seed makes the best plants. The best soil for seed-sowing is leaf-mould and sand, with the surface sifted fine, and a little loam in the rougher stuff below. As soon as it is possible, prick off the seedlings singly in boxes, about 2 in. apart, and they would be the better of a gentle heat at this stage to induce them to root freely, and if at all late to make growth. In any case the boxes must be kept close for a few days, then admit air, and when the plants touch each other pot off singly in 3-in. pots, harden off, and plant out as before directed. Or if they are pricked out or transplanted to 3 in. apart in boxes instead of 2 in. and have 2½ in., or 3 in. of soil, the potting may be dispensed with, and the plants taken up with good balls, and put direct out into the beds.

Single varieties of Petunias should always be used for beds, as, though the double ones are very fine, the rain spoils the blooms, so that they should be kept for pots indoors.

Phlox Drummondi.

This is another extremely valuable town flower. Its colours surpass even the Verbena in brilliancy, and the trusses are much larger. The new grandiflora varieties far surpass the older ones in the size of both plant and flower; but they are somewhat taller and more straggling in growth, and we fancy they do not bloom quite so freely. Sow the seed in light rich soil in gentle heat in March; cold frames early in April, or at the end of April out-of-doors. The plants do as well or better, becoming more robust and dwarf when sown out-of-doors than by the other method; but as they are rather slow in making a start, the season is rather far advanced before they come into bloom. So that, where it is possible to do so, it is better to sow under glass, in a greenhouse, frame, or warm window, as for other half hardy things; prick off singly in boxes, 2 in. apart, when ready, and plant out 8 in. or 10 in. apart in good rich soil. The plants may, if early enough, be potted singly when pretty well advanced, and when well rooted out, be planted from these into the beds and borders; in this way the roots do not get injured as they sometimes do if left too long in boxes. If good fresh seed can be had, and the plants are grown with plenty of room, air, and light, they will be so strong that they will shoot out laterally at the base, and may be pegged down like Verbenas; but if at all weak they will leave only a single stem, and had better be planted rather close, and tied up to neat stakes. Like all other annuals, these delight in a good deep rich soil in which to grow, and it should be light rather than heavy in texture. They need plenty of sun to do well.—B. C. R.

To Get Rid of Slugs.—Take a bull's-eye lantern and a small phial of liquid ammonia

(hartshorn), go round your borders after dark, and with a feather put a drop of the ammonia on every slug you see. This is a cleanly and effective method of killing the pests.—A. J. S.

MY COTTAGE GARDEN.

In an out-of-the-way corner of Dorset will be found the above. The cottage used to be much admired, chiefly, I think, on account of its being literally covered with an ancient Vine, at all events on three sides, and it might have easily been trained all round; but it was found that on the north side Grapes would not ripen, therefore the Vine was cut; but to make matters harmonious, on the eastern corner I planted a climbing Rose, which now, after ten or twelve years, lies on the roof, and in June a wheelbarrowful of dark crimson Roses may easily be had, and at such time the scent of them may be well said to load the air. What this Rose, is called I do not know, but it is a common kind in the southern counties; it is scarcely ever pruned or dressed except with a reaping hook, but is little the worse for its age, and the secret of its immense size is that the roots are exactly over the drain from the cottage pump. In front of the house, across the public road, is an orchard, a lovely sight in spring, a sea of scarlet and white blossoms, and in autumn the glories of Pomona in yellow and red hang in ropes when the season is favourable. As if it were an adjunct, three or four old Apple trees stand in the cottage garden, venerable sires, and yet annually young, as for twenty-five years they have never failed with a crop, and yet they are covered with horrors that would drive a modern horticulturist mad. They are grey with Lichens and green with Moss, and masses of American blight all over them. We are told to use a stiff brush and Gishurst Compound. You might as well try to Gishurst Compound the Monument. I tried once to paraffinise one of them, but found it labour in vain.

These trees never send forth any apparent shoots; no young wood is ever seen; yet from the horny-knotted extremities every season come the delicate tresses of flowers and the surrounding leaves. There is no better Apple anywhere; they are all the same kind, and called the Pitcher, good either for the table or cooking. How old are they? Well, it is impossible to say; but, hazarding a guess, they look as old as I am—sixty-eight years. Beneath these trees are spring flowers, double Primroses, Violets, the latter a weed in the garden (I tried to eradicate them, but gave it up in despair, so now they have their own way), Daffodils of several kinds, two fine groups of the White Lily, and a great bush of the China Rose as old as the Apple trees. This shows what will grow under trees, for the same arrangement goes on from year to year with success, and all attempts to introduce change have signally failed. All they require is occasional digging up of the tubers and replanting, and in autumn a liberal cover of old stable dung, which is forked in when the frost is over. The reader will find the moral of this article stated at the end of it; all I now wish to observe is, I wish I had known the drift of it twenty-five years ago.

About 100 yards to the north is a small, swift-flowing river, sparkling and clear in summer where the swallows skim and gambol all day over the water and the meadows beyond, but at times of flood frightful to look at; the bridge over it shakes with the force of the water. My cottage stands on the highest bank, therefore I am not in danger of being flooded, but the reader will perceive that the situation is low and does not lack moisture. From the river above came a small stream of water which went half round the orchard at the side of the road till a few years ago, when the sanitary authorities enclosed it in pipes; so that for anything the wayfarer knows, it does not exist. In my opinion this step was useless, and was the cause of the death of my Vine, whose roots penetrated under the narrow road into it. So we will return to the Vine, which I will endeavour to describe. This was planted just inside the garden wall and nearest the streamlet across the road; it was arranged very judiciously in two branches, one nailed horizontally close to the ground, so that the rods went up a large extent of wall without windows, and to this I applied the rod system, viz., removing old rods occasionally to allow a new one to spring from the base. The other branch was led over the wall and made a deep, heavy knee, and then was led in various branches over the door and round the windows till the front was one mass of foliage in summer.

In this part the spur system was followed, *i. e.*, a Vine forms as it gets old large knots, from which spring vast numbers of buds in spring. From the great trouble it occasioned it was allowed to show bloom before disbudding all but once. With the exception of the trouble, I preferred this latter system, as the Grapes were much finer, though the aspect was to the west. Here they ripened in former years as well as under glass, and as rich in colour, a brown yellow, the true colour of the Chasselas. After the streamlet was confined the entire Vine lost its beauty; blight seized upon it; so that very sorrowfully I had the whole front part removed, though part of the garden side still remains. At that time I found it to be an independent Vine, for at a certain bend near the ground it had rooted itself deeply into the border.

Dorset. W. T.

Marvel of Peru (Mirabilis jalapa).

Large Flowered Christmas Rose (Helleborus altifolius).—This, in addition to being larger and finer than the ordinary Christmas Rose, is certainly an earlier bloomer, and for those who value cut flowers, or flowering-plants in pots, during winter, and who have but a limited amount of heated glass structures, I do not know of a more valuable plant than this is; it only needs the protection of a glass covering to keep its blossoms from being dashed by heavy rains, and it will be in full flower during the dullest and darkest days of the year. Last season I procured half-a-dozen clumps of this variety, and planted them on a well-prepared border, in two rows, in such a way that an ordinary two-light frame would cover them. They have already produced blooms in abundance; there are large quantities of buds yet to open for succession. They are admirably adapted for furnishing vases, as, if cut in the bud state, they readily expand in water, and last as long as any flower with which I am acquainted. I would recommend any one beginning to grow this useful plant to give the soil a good preparation, choosing an open sunny aspect for it, where the crowns can be well ripened, and every season the plants will produce great quantities of flower. If well trenched and manured they would not require re-planting for at least seven years; but a top-dressing of well-decayed manure, and a little liquid manure, might be given during the growing season when the plants are making their foliage, as upon the size and substance of the leaves will depend the size of the flowers. If required for pot culture, care should be taken to protect the foliage from injury; when the blooming season is over, they should be protected by a frame until genial weather permits them to be plunged into the open air. Hardy subjects like the Christmas Rose frequently suffer when removed from under glass, for although hardy enough to withstand our severest winters when continuously exposed, their growth, made under more exciting circumstances, will not withstand any sudden variations of temperature. For this reason it is advisable to keep them in as cool a position as possible when in flower, so that the growth of young foliage may not be excited before its natural season.—J. G.

White Flowers for Christmas.—The inevitable demand for flowers at our great winter festival has largely been instrumental in promoting an increase in kinds of plants suitable for the production of winter flowers, and in some establishments the chief energies of the winter seem devoted to the production of a huge lot of flowers for decoration at that season. One of the easiest, because hardiest, of plants to produce white flowers is the Chrysanthemum, and the latest and best kind is Princess Teck, a large, French, white, incurved kind. The flowers of this Chrysanthemum are in great demand for church decoration, as they can be produced far more cheaply than Camellias or Gardenias. These latter are the choicest of white flowers, but owing to the expense incidental to their production in mid-winter are necessarily costly. White Cyclamen blooms may be had in great

abundance, large plants of these having from thirty to fifty blooms expanded at once. The Cyclamen is grown for the London market literally by hundreds of thousands, and now that its culture is better understood, few plants are perhaps more easily grown. One of the best of white flowers for bouquets is the double white Chinese Primrose. In some gardens these are kept by hundreds for the supply of cut flowers alone. The Tuberose is a delightful winter flower, delicately perfumed, and the individual flowers are fixed on wires in the making of bouquets. Then there is the beautiful Eucharis amazonica, the flowers of which are large, cup-shaped, and of the purest white. Under careful culture this can be induced to bloom almost at any season. Then there are white Roses and Christmas Roses, white Narcissi, Roman Hyacinths, and Tulips—in fact, plants that will produce white flowers at Christmas are plentiful enough.—A. D.

Hose-in-Hose Polyanthuses.—This section of hardy, spring-flowering plants would seem to be amongst the earliest of all to flower, as several kinds are now more or less in bloom. Golden Gem, a remarkably effective yellow kind, is a very robust grower, and will, without doubt, prove to be a fine spring bedding plant. The flowers are large, and, like a true Hose-in-Hose, are produced on the stems in couples of rows of petals separated by a short interval. This is a pin-eyed variety, but this naturally detracts nothing from its decorative qualities. Golden Queen is the duplicate of the former, except that the flowers are thrum-eyed and a shade richer in colour. Cloth of Gold is a deeper hue still, but this is also pin-eyed. The finest white Hose-in-Hose is Avalanche, the flowers of which are large, pure in colour, and borne in large, compact trusses. The old white Hose-in-Hose has large flowers of a fresh white tint, and is a most valuable hardy spring flower Perhaps one of the most effective kinds for massing is the crimson Hose-in-Hose, as dark rich hues are in great request in the early spring garden. This is also a very robust grower, and stands the summer drought well. The fancy section of Duplex Polyanthuses gives a great variety of novel and curiously-marked flowers, all of which are exceedingly attractive whether used in beds or planted singly in borders. It will probably soon be possible to select at least a dozen good distinct bedding kinds of these early Hose-in-Hose varieties.—B.

Lilium longiflorum.—Lilies are becoming so popular, and so many are wishing to take up their culture, that it may not be amiss to direct attention to this fine species. It is one of the most manageable and least capricious members of this fine family, and I therefore counsel all embarking in Lily culture to include it in their list. Its large white, trumpet-shaped blooms are very handsome, and as the plant itself is a moderate grower, that is to say, although not deficient in vigour, the flower-stalks do not run up so high, as is the case with many kinds, the flowers are not so liable to become bruised in stormy weather. This Lily likes a good sound loam to grow in, and, like the rest of the family, prefers a partially shaded, somewhat cool situation. There are many varieties of it, some of which are as yet comparatively rare; but the typical form is very cheap, good bulbs costing only about 4d. each, so that it lies in the power of all to grow this beautiful species.—J. C., *Byfleet.*

FRUIT.

PRUNING VINES.

Amateurs seldom attempt forcing Vines early, and, as a rule, it is better that they should not do so, for, unless a certain amount of practical experience is brought to bear on the matter, failure would be likely to be the result. Even in the case of thoroughly established, strong Vines in fruitful condition, Grape-growing that entails the necessity of starting the Vines, even at the close of the year, is a very different operation, requiring a great deal more skill and watchful attention than hastening the natural spring growth by the application of fire-heat towards the end of February or during March. Nevertheless, now that the leaves will have all, or nearly all, fallen, and where the fruit has all been cut, it is better to prune at once. To make sure in a way that gives the wood sufficient time to heal up the cells severed in pruning, two months should elapse before the Vines are either excited by fire-heat, or come on of their own accord. Another advantage gained by early pruning is, that plants wintered in the houses under the Vines receive so much more light by the removal of the shoots. In the matter of pruning, two distinct methods are practised; one is known as the long-rod system, and the other the spur.

The Long-rod System consists in taking up one or two young canes from near the base of the Vine each year, which, at the time of pruning, are shortened back to from two-thirds to one-third of their entire length, the crop being borne on the young rod or rods from the bottom up to where they are cut back, and on the old cane that has produced them above where they were severed, except in cases in which it was cut away as soon as the fruit was removed; in that case the young one is generally left nearly the entire length of the rafter; but this method is now comparatively little practised, and never had very much to recommend it, although by it larger bunches are often produced than by the other system. Amateurs are more likely to succeed under

The Spur System, though the Vines in time, owing to the length which the spurs assume in the course of years, have a less sightly appearance than in the case of the long-rod system. This is a fault which can, however, be avoided by yearly cutting from each rod a few of the spurs completely; young shoots will spring from the base where these have been removed, and will take their place, though it often happens that such shoots do not show fruit freely the year after they have been formed. It is, however, always better to prune with a view to a crop than for mere appearance sake, and I should not recommend any bearing wood ever being shortened closer than to where a good plump eye can be retained, even should this be the second above the base of where the current season's shoot had sprung, and in no case to sever the shoot too near the eye that is retained. The advantage of pruning in this fashion is, that the second eye may produce a good stout bunch, wherein the usually weaker bud at the base of the shoot may show no bunch, or one that is a sort of half bunch, half tendril; and if the lower eye shows fruit satisfactorily, then the shoot from the second eye can be removed altogether.

Where Vines are strong enough to bear freely, there is little to be feared in their showing a sufficient crop, provided the wood has been fully ripened, unless where over-cropping has been practised, or they have been so grossly neglected as to allow them to become a prey to red spider or thrips early in the season, long before the leaves had fulfilled their allotted functions.

There is one other point to which I would direct the attention of amateurs in Vine-pruning, and that is not to retain too many spurs on each rod; it is a common occurrence to see a spur retained at the greatest number of the joints of the rods first made, which is much too close, crowding the roof with small half-developed leaves; whereas, if the spurs be from 1 ft. to 15 in. apart, they are quite near enough.

Winter Dressing.—In the case of Vines that are pruned now with a view to their being started more or less early during the winter, it will be as well to give them their winter dressing at once. Before applying this, it is usual to strip off some of the outer bark, but in this operation I would especially urge amateurs to be cautious, and only take off such as is quite loose and hanging in a dead, stringy condition; the unnatural practice of close scraping, so as to remove the whole of the outer covering almost down to the living inner bark, polishing the rods off smooth like a knotted walking stick, is fatal in its effects, preventing the Vines ever growing and thickening as they ought to do. This scraping process I am aware is often done with the intention of removing the eggs of red spider, thrips, and other noxious insects deposited in the inequalities of the bark, but in this case the cure becomes worse than the disease. After removing just the loose outer portion as above described, dress at once with the usual mixture of clay, sulphur, a little Gishurst and soot, and fresh cow manure, the latter to help the dressing to stick, stirring all well together, and using it about the consistency of thick paint, brushing it in thoroughly to get it into every crevice, especially about the base of the spurs. After they are dressed, the rods may either be tied up in their places under the rafters, or across the house over the front path, if there happens to be one; in this way most light will be admitted to whatever plants occupy the house during the winter. T. B. S.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

December 20.—Sowing Cucumber seeds to produce plants for March; introducing another batch of Keen's Seedling Strawberry plants into a heat of 58°; turning walks where gravel has become discoloured; preparing pit for Madame Falcot Roses; tying down Pelargoniums after potting and stopping them. Plants in flower—Cytisus canariensis and Attleana, Epacris Eclipse, Monochætum ensifolium, Cinerarias, Lily of the Valley, Begonia incarnata, Goldfussia isophylla, Thyrsacanthus rutilans, Roses, Poinsettia, Tom Thumb Pelargonium, Tydæa splendens, Schizostylis, Erica gracilis autumnalis, Salvia splendens, Primulas, Euphorbias, Callas, and several kinds of bulbs.

Dec. 21.—Putting Schizanthus in pots; getting up Rhubarb for forcing; pruning and nailing Cotoneaster; plunging Fig trees in pots in a hotbed of leaves; wheeling manure on to vacant land; making a new Mushroom bed, the fourth this season; pruning trees, and white-washing walls and cleaning woodwork and glass of third Peach-house.

Dec. 22.—Potting Gladiolus in one-third loam, scarcely one-third manure, and rather over one-third peat and sand; also more Mint; putting into force some Lily of the Valley, a few Ghent Azaleas and Deutzias, a batch of Jules Margottin Roses, a few Dielytras, some Cinerarias, and also Azalea vittata punctata—temperature 55° to 60° at night, and from 60° to 65° during the day; tying Fig trees after whitewashing the walls and cleaning the trellis; also Raspberry canes; staking late-sown Mignonette; putting cases over Watercresses to protect them from frost.

Dec. 23.—Sowing seed of Bromham Hall Melon and placing it in bottom-heat; planting some standard kitchen Apples; putting in Vine eyes; pruning Apple trees in orchard; clipping tops off shrubs in pleasure-grounds where too high; cleaning Violets in frames; also herb beds.

Dec. 24.—Sowing fifty pots of Nemophila; potting in Sphagnum Odontoglossum coronarium, which requires to be grown cool and shady; also second batch of Potatoes for forcing; shifting young tree Mignonette into 6-in. pots; dividing Irises and planting them again in border; planting and staking Cherry and Plum trees; getting Endive into heat twice a week, so as to have it well blanched and fresh; re-filling baskets for conservatory with Nemophila and Silene; putting Alyssum and old Verbenas into Vinery for cuttings; placing all Mignonette from pits on late Vinery shelves, so as to get it in the sun; examining pot Carnations for fly; washing Gardenias.

Glasshouses.

Epacrises.—Although these are strictly greenhouse plants, and will succeed through the winter in a temperature just above freezing, still, where a good stock exists, it will be found useful to have a portion in bloom early, which may easily be accomplished by keeping some amongst such of the greenhouse plants as require the most warmth, say 45° or 46° at night, with something more than this in the daytime. For this purpose those should be selected that made their growth first, and were turned out correspondingly early in the open air, as these plants at once set their flowers as soon as put outside in the summer, and by this are influenced in their time of blooming. The large-flowered, upright-habited varieties are the most useful for blooming early, and they are also the best for general use, especially for providing cut flowers, as every shoot of the preceding season's growth may be cut without injuring the plants; in fact, to keep the erect-growing kinds from getting too tall and thin, it is necessary to shorten the whole of the shoots to within a few inches of where they were cut back to the year previous. It seems strange that there are not more of these most serviceable plants grown than there are, so easy are they to manage, and not subject to get into a bad condition in the way that many of the more tender hard-wooded plants are; added to which their leaves are so stout as to almost defy the attacks of the generality of insects, another important consideration.

Large-flowered and Fancy Pelargoniums.—Those plants of the large-flowered section that were shaken out the latest after being cut back and treated in the usual way, should by this time have made sufficient new roots to permit of their being moved into their

blooming pots, which should be about 8 in. in diameter. All Pelargoniums are better hard-potted, but for this section particularly the soil should be made very solid ; it should also be in a medium condition as to moisture, and little water should be given until the roots have had time to fully establish themselves. There is no description of soft-wooded plant which makes any growth through the winter that from this time to the end of February requires to be kept with the soil so dry as these and the fancy varieties, without which they never can be grown satisfactorily. They should have all the light possible, and be kept at a temperature of about 40° at night, with a little air every mild day, but not exposed to keen winds. The dwarf-growing, free, early-flowering, decorative kinds so largely cultivated by market growers, and which are the most useful by far for general purposes, as they will bear enough heat through the winter to have them in bloom by the beginning of March, should be kept now at a temperature of 45° or 46° at night, with sufficient warmth in the daytime to permit of a free admission of air, which prevents their becoming drawn. As soon as the flowers show freely, which they ought to do by this time, the plants will bear a little liquid manure once a fortnight or so, but they must not have it over strong, or it will cause them to run too much to leaf. They ought to be kept close to the glass in the lightest house available, and especial care should be taken to see that they are free from aphides, on the first appearance of which they ought to be fumigated.

Fruit.

Vines.—Late Vines, being quite clear of foliage, there will be little now to engender a damp atmosphere, particularly if internal borders are, as they should be, covered with mats or dry straw, so that if the fruit has been well ripened, it would keep in plump condition on the Vines for at least three months ; but this is undesirable, taking into account the future well-being of the Vines ; provision should therefore be made for keeping the bunches in bottles of water, and all should be cut about the second week in January. We have never experienced any difficulty in keeping Grapes in good condition till June, except once, when they were left on the Vines until the middle of February. In that case, when placed in water, the sap having become active by the mild winter of that year, the berries cracked, and, as a matter of course, decayed, so that under no circumstances should harvesting of the fruit be deferred beyond the second week in the New Year ; Vines should then be at once pruned and otherwise afforded the proper conditions of rest. Proceed slowly with the forcing of early houses, preferring rather to make up lost time after the Grapes are set than to risk the production of tendril-like "shows" by hard forcing. Pot Vines, if placed, as they often are, close to hot-water pipes, will need a large amount of water. When practicable, it is always best to plunge the pots in a bed of leaves, both to save watering and afford a slight bottom-heat.

Peaches and Nectarines.—Pruning, tying, cleaning of houses, &c., should all be now completed. See that inside borders are well moistened through, and kept so by the application of tepid water whenever necessary. A thick mulching of litter or Oak leaves not only keeps the borders in an equable state, both as to moisture and warmth, but gives off ammonia, which, till the trees come into flower, is beneficial, and prevents the necessity of constant syringing to maintain the proper amount of moisture.

Figs.—As soon as the pot trees that are to yield the first supply of fruit have begun to expand their terminal buds, increase the temperature and air-moisture, and let the trees have an abundant supply of warm manure water, and in the absence of litter or leaves to give off the desirable ammoniacal vapour, the floors and walls may also be occasionally syringed with the same. Keep the glass clean, and the trees as close to it as circumstances will permit. The earliest planted-out trees may now also be started by the turning on of sufficient heat to maintain a night temperature of 45°. Syringe the trees in dry or mild weather, but the floors and walls only in frosty or damp weather. Complete the pruning, tying, dressing, and cleansing of houses and top-dressing of borders at the earliest period, and to effectually rest the trees, keep them well supplied with air till the time arrives for starting them.

Strawberries.—The plants that are being started on shelves in Vineries, Peach houses, &c., ought to be regularly syringed till they come into bloom, as a preventive against red spider. It is on this account—liability to attacks of spider—that we prefer to start them in a frame filled with leaves, for though plenty of both top and root moisture will keep away spider, some plants are almost sure to escape notice and get dry, and then its advent is a certainty. When first placing them in forcing quarters examine them to see that the drainage is clear and the balls free from worms. Rub off any mossy vegetation that may have formed on the surface, but on no account break up the surface soil, for to do this is simply to destroy many of the best roots. Those plants that from want of frame room must perforce remain in open quarters should at least have sufficient protection to prevent the pots being smashed by the action of frost, and felt, boards, or tarpaulin should be used to throw off rain and snow.

Vegetables.

It will now be necessary to go over plots of Greens and remove all decaying leaves. Such vegetable refuse makes a valuable manure when it can be dug in whilst in a green state, but if this cannot be done it should be thrown together and intermixed with a little fresh lime, which will add to its value as a manure. Potatoes should be carefully examined ; all the early seed tubers should be laid in single file to sprout, on floors or shelves, free from frost. Some of the first earlies may now be put in shallow boxes of leaf soil, and placed in frames to start them ; and as soon as fairly rooted into the mould, they should be finally planted in forcing pits or pots ; we find the latter a very convenient mode of growing the earliest batch, as they can be moved from place to place as circumstances demand. Myatt's Ashleaf Kidney and Fenn's early Market Round are both excellent varieties for pot culture. If not yet done, Asparagus plantations should have a thick covering of well-rotted manure, but no alleys should be scooped out to cover it ; such a proceeding is not only useless, but hurtful. New plantations of Horseradish and Rhubarb may now be made at any time, and established plots should be manured and dug over. Still keep Globe Artichokes well protected, though if time can be afforded, the protecting material should be removed when there is no likelihood of frost, and again applied on the first indic tions of it. Let all vacant plots of ground be manured, and dug, trenched, or ridged up as soon as possible, in order that they may have the fullest exposure to the ameliorating influences of the weather. A plan of cropping for the forthcoming season should at once be decided on, and in making it out see that the various plots have the crops varied as much as possible from those of last year. Taking the same crop twice consecutively from the same ground not only impoverishes it more than it otherwise would be, but the produce is less, the only exception being when the ground is deeply trenched.

The Codling Moth and Apple Grub.

GARDEN ENEMIES.

THE CODLING MOTH.

(CARPOCAPSA POMONANA.)

THERE are few persons to whom the grub of this little moth is unknown, as it is found only too commonly in Apples and Pears, and at times in such abundance as to seriously injure the crop. It is very difficult to keep in check, and, unfortunately, its natural enemies are not very numerous, Many of the moths are killed by birds, and if the weather be cold and damp about the time they make their first appearance, many, no doubt, perish before they have laid their eggs. As the fruit containing grubs generally ripens and falls some time before the sound portion of the crop, it should be collected and destroyed, for each Apple or Pear is nearly sure to contain a grub. In gardens where there are espaliers or dwarf trees, the fruit on them should be carefully looked over from time to time, particularly in May and June, and any showing signs of a grub being within should be gathered and destroyed ; these may be known by their having a black or reddish-brown spot on them, which is the entrance to the gallery the grub is forming. In the spring any rough loose bark on the stems should be scraped off, and any chrysalides which may be found destroyed. The moths should be killed whenever they are detected. The moth makes its appearance in the month of May, and shortly afterwards begins to lay its eggs, generally depositing them in the eyes of the Apples or in the hollows near the stalk, usually selecting the firmer kinds of fruit. In favourable weather the grubs are hatched in the course of a few days, and immediately begin to eat their way into the fruit and take up their position near the core, eating the flesh of the Apple and making a connecting gallery with the outer world ; this allows a little air to reach the grub, and also enables it to get rid of some of its droppings, which are found in great quantities in any worm-eaten Apple. The fruit continues to grow in spite of the grub, and, as before stated, falls often with the appearance of being ripe long before the uninjured fruit. The grub becomes fully grown in about three weeks or a month (in June or July), and then leaves the fruit, whether it has fallen or not, and chooses some sheltered place on the stem of the tree or beneath the surface of the ground, and spins a cocoon like a silkworm round itself, in which it changes into a chrysalis. In a few days the moth comes out and commences to lay its eggs on the fruit, so that in July, August, and even September, the fruit is attacked by a second brood of grubs ; this shows the desirability of the Apple grower taking every precaution to destroy the grubs of the first brood, as on the number of those which become moths depends in a great measure the amount of damage caused by the second brood. The moths from this brood do not not appear until the following spring, the insect remaining during the winter in the chrysalis state. The moth measures about 8-10ths of an inch across the expanded wings ; the front wings are pale grey, with curved, transverse, darker fine lines and bands ; on the lower and outer angle of each there is a large reddish-brown spot surrounded by a golden band ; the lower wings are of a brownish-orange ; the thorax and body are brownish-grey. The grubs are about ½ in. long when fully grown, and are fat and fleshy ; they vary in colour from a yellowish-white to almost flesh colour. The head and a large spot on the first joint of the body are black or very dark brown, and on each joint are several small blackish tubercles, from which grow a few fine hairs. They have fourteen joints, not including the head on each of the three first, as well as on the sixth, seventh, eighth, and ninth, and, last, there is a pair of legs. The cocoon is oval, and about 6-10ths of

an inch long, whitish in colour, and when found on the stem of the tree small pieces of the bark are mixed with the web of which it is formed. Within this cocoon will be found the reddish-brown chrysalis. S. G. S.

GLASSHOUSES AND FRAMES.

Geraniums and Primulas for Winter Blooming.—We have received from Mr. John Green, Thorpe Nurseries, Norwich, cut blooms of the following kinds of Geraniums, which he grows for winter blooming. They were all bright and good, and suitable for the purpose intended. Single kinds:—Scarlet Vesuvius, scarlet; Salmon Vesuvius, salmon; White Vesuvius, white; Lady Sheffield, pink. Double kinds:—Wonderful or Double Vesuvius, scarlet; Madame A. Baltet, white; Madame Thibaut, pink; Ernest Lauth, magenta. Mr. Green also sent us blooms of semi-double Primulas, which are very pretty and useful for cutting. The seed was sown last spring.

Epacrises.—These endure hardships better than Heaths. Plants of them that lose their foliage and appear almost dead, from being left too long in warm dry rooms in winter, seldom fail to push forth as freely as ever again in spring if kept a little warm till they start, and occasionally dewed overhead. The must be badly used indeed if they fail to revive under such treatment. From among the many varieties of these now in cultivation the following is a good selection:—Alba odoratissima, carminata, Albertus, delicata, densiflora, elegans, grandiflora, Kinghorni, multiflora, Mont Blanc, splendida, and Queen Victoria. The one we now figure, E. miniata splendens, is one of the most graceful, and may be grown to a large size. They require a compost of peat and silver sand, firm potting like the Heath, and efficient drainage. Unless large specimens are desired the plants will do well enough if potted once in two or three years. They should be cut down after flowering, and I have always noticed that, unlike soft-wooded Heaths, which prefer the open air in summer, they do best in a cool greenhouse or pit during the season. Some of the varieties make long straggling shoots, but these are not unsightly, and the longer they are the longer will the wreaths of flowers on each shoot be, if the plants have been grown under a good light, with plenty of air, and are well ripened. It is best to use the Epacris for flowering in early winter or spring, which gives the plants time, after being cut down, to make a good growth the following summer; when cut down late the flowers are not so abundant nor so fine. Their roots will stand pruning when it is needful to keep them in small-sized pots.

Epacris miniata splendens.

Lapagerias as Standards.—Few plants are better adapted for covering umbrella-shaped trellises than Lapageria rosea and its white variety. The flowering shoots can be tied so as to hang loosely and gracefully from the trellis, a position in which they can be seen to better advantage than when trained over balloon or pyramidal-shaped trellises on which we too frequently see them; moreover, as standards they can be employed in the conservatory to better advantage than in any other form, inasmuch as they allow of other plants being placed beneath them.

The Giant Christmas Rose in Pots.—This fine early-flowering Christmas Rose makes an admirable pot plant in winter. We lately saw it treated in this way in a garden in which one plant in a 10-in. pot bore upwards of 100 buds and blossoms. Such plants may be obtained either by growing them continually in pots, or by planting them out during summer and lifting them and potting them in the autumn. It is a good plan to put a sheet of brown paper round the plant when the bloom-buds appear, allowing the light only to fall on its top. This brings the flowers well up among and above the leaves, which, if the plants be wanted for conservatory decoration, is very desirable. Under this treatment, too, the flowers come whiter than when exposed to very bright sunshine. This Hellebore might also be made to form an effective feature in the conservatory if planted in quantity in the autumn, so as to form an undergrowth to Palms, standard Chrysanthemums, and similar plants.

Aster grandiflorus for the Conservatory.—This, one of the latest-blooming kinds of Michaelmas Daisy, is well adapted for lifting and flowering in pots in the conservatory. Its large flowers, which are of a very showy bluish-purple, supply a colour wanting in Chrysanthemums, and well grown bushy plants of it would greatly enhance the effect of a mixed collection of Chrysanthemums, scarlet Salvias, and similar plants used for autumn indoor decoration. We lately saw fine bushy specimens of this Aster just opening its bloom-buds, and which, if lifted, would be well fitted to the purpose alluded to. Associated with this kind were also in flower Aster terminalis, A. paniculatus, A. Novæ Angliæ, the dwarf A. discolor, and A. ericoides.

Soil for Palms.—Though generally found growing in peat, nearly all Palms succeed equally well in loam. We lately saw examples of Cocos Weddelliana and other good Palms in a London nursery growing entirely in yellow loam, and seldom have we seen more healthy plants, the foliage being much darker and more glossy than that in plants grown in peat.—S.

Watering Camellias.—Many who have well attended to their Camellias during the summer and autumn are apt to cause themselves irreparable loss in the matter of bloom by neglecting to water them properly at this season. Those rules which apply to most hard-wooded plants with respect to watering in the winter do not hold good in the case of Camellias. They must not stand dry, and if they once become so, water them twice in the interval of a day, so that the balls may become thoroughly saturated. In dull, damp weather, when judging in the ordinary manner is deceptive, tap the pot; a clear ringing sound denotes the necessity of a good moistening. Bud-dropping is extremely vexatious, and a want of moisture at the roots and a too confined atmosphere are fertile sources of mischief in this way.—C. B.

Wintering Echeverias.—Where room under glass is scarce, flower garden Echeverias may be stored away in a shed or tool-house. If packed closely in boxes they will need no water during the winter, and will endure uninjured from 10° to 15° of frost. If the winter be exceptionally severe, a mat or two thrown over them will be sufficient to insure their safety. I have kept them in this way when the thermometer has registered 18° and 20° some nights in succession.—J. B.

SEASONABLE NOTES ON ORCHIDS.

In commencing Orchid culture a selection of species should be made which will bloom at different periods, so that a succession of flowers may be had all the year round, and this should be done with some degree of partiality for those which display their charms through the dull months of winter.

Oncidiums.—Amongst the best which bloom at this time of the year may be named Oncidium varicosum majus and O. Rogersi; of these, the first has been introduced most abundantly, and amongst them many are now in flower that differ considerably in size and brilliancy of colour, but all are beautiful and specially valuable for winter decoration, for with a little management as regards retarding a few plants will produce a harvest of flowers from October to Christmas. O. varicosum may be grown in a pot or in a basket, and suspended from the roof, whichever way is most convenient; it matters not which, as far as the plant is concerned, provided all its surroundings are sweet and clean, and the atmosphere sufficiently humid. Some say they get tired of Oncidiums because they are all yellow, but O. incurvum is a charming kind, the flowers of which are white and rosy-pink; individually they are small, it is true, but they are produced in great abundance upon long branched spikes; it is now opening its delicate flowers, which will last till January if not sprinkled with water by the syringe.

Lælia autumnalis.—We have a perfect gem, which is throwing up dozens of spikes, each bearing two, three, and five blossoms, which are of large size, measuring 3 in. or 4 in. in diameter; the colour in the sepals and petals is deep rosy-purple, and the lip rose and white with a stain of yellow in the centre. They last long in a cut state, and in addition to their pleasing colour, they emit a delicate perfume; as regards treatment, all that is needed is good drainage, good peat, and living Sphagnum Moss to retain moisture at the roots; plenty of air, too, when growing must be given, and the plants must be placed in such a position that the sun will shine upon them in the morning.

Pleiones, or as some term them Indian Crocuses, are now and indeed have been very gay for at least a month past. A beautiful succession of these may be kept up by placing some in a cold house. The brilliant contrast of colours in P. lagenaria and P. maculata is truly charming, whilst the tints of P. Wallichi are soft and rich. These plants begin to push up their young growths immediately after flowering: therefore, when the blooms fade, repot them at once in order that the new growths may reap the full advantage of the fresh soil.

Odontoglossums.—The beautiful Odontoglossum Alexandræ must ever be a favourite

with Orchid growers; its large flowers never fail to elicit admiration. Of this Odontoglossum there are numerous varieties, but amongst the whole of them a bad one could not be found. It is now pretty generally known that this Odontoglossum succeeds best under cool treatment. Odontoglossums like abundance of air, but it must not be admitted irrespective of external conditions, for if that were done, they would become starved and shrivelled. The Sphagnum should be kept in a living state upon the surface of the pots, and should never be allowed to become dry at any season; a few plants of this species will keep up a succession of flowers during the winter months.

Calanthe Veitchi is another winter-blooming plant, totally different from anything previously described, and extremely beautiful. It is, however, far too often starved, and consequently does not produce that abundance of flowers which it otherwise would do. The pseudo-bulbs are from 12 in. to 16 in. high, partially deciduous, or, perhaps, quite so; still, it sometimes retains its foliage until after it has bloomed. The flower-spikes measure 2 ft., 3 ft., and 4 ft. high, and bear numbers of rich rose-coloured blossoms. After blooming the plants should be allowed to rest for a short time; then they should be re-potted, using for the purpose loam, leaf-mould, peat, and cow manure in equal parts interspersed with some Sphagnum, and during the growing season they will be benefited by applications now and then of weak liquid manure.

THE SHRUBBERY.

Hardy Azaleas.—These are deciduous shrubs, which put forth their flowers before the leaves, or the leaves and flowers are developed simultaneously. Azaleas may be classed in the first rank of deciduous shrubs cultivated for the sake of their ornamental flowers; yet, notwithstanding the beauty and variety they present, they are comparatively neglected. Amateurs having small gardens and limited means are deterred from planting them, probably because they are usually described as peat-loving plants. It is true that they attain greater perfection in a carefully-prepared soil than they do in a close, adhesive soil; but in this respect hardy Azaleas are less exacting than most Rhododendrons, and will flourish in places where Rhododendron ponticum grows freely. It is worth noting that most of the hardy Azaleas grow naturally in swampy places, but not necessarily in boggy ground. But the hybrid varieties commonly cultivated succeed well in light, thoroughly-drained soil. In the absence of peat, leaf-mould may be used, and where the soil is heavy, sand should be added. Of course, the proportions of leaf-mould and sand necessary or desirable depend entirely upon the nature of the soil upon which one has to operate; and a light, porous soil requires no modifying. Planted singly or grouped, Azaleas are very effective, but they are not so well suited for mixed shrubberies, nor do they grow and flower so freely when mixed with other subjects. For the variety and brilliancy of their usually fragrant flowers they are unrivalled, and many of the tints and shades of colour are almost unknown in any other class of plants. They range through all shades and hues of yellow to orange and red to crimson, with some very singular mixtures of yellow and red; there are also white-flowered varieties. Another strong point in their favour is that they produce their flowers soon after the beauty of spring-flowering shrubs is past. Being slow-growing subjects, they should be planted rather thickly, for they are some years growing and spreading 3 ft. or 4 ft. Azalea mollis is a dwarf-growing kind, with waxy, well-formed flowers, which is highly effective in spring. When placed in a greenhouse all the hardy Azaleas flower early and freely, and are very attractive objects.

Fortune's Bamboo (Bambusa Fortunei).—A plant like this so distinct in leafage should more often be seen in English gardens. The fresh green foliage and irregular outline of this Bamboo produce a very pleasing impression, and the fact of the plant resisting with impunity the rigours of a severe winter, retaining all its freshness through periods of hard frost, renders it of great and special value. There is a pretty, variegated form of it, and the two would form a pleasing picture planted in close companionship. This, like all the Bamboos, likes a fine, rich deep soil, and its good qualities render it worthy of some extra pains being taken in the preparation of the soil.—J. C.

Honeysuckles on Fir Trees.—In our shrubbery borders and woodlands we have some fine Honeysuckles that have been planted near the bare stems of Scotch and other Fir trees, and supported until they reached the lower branches; after that they support themselves and make a fine display. Some of the Clematises would also look well in similar positions.—G., *Maidstone.*

ROSES.

Rose Growing.—Being uninitiated in the art of Rose growing, it was with some misgivings that I procured last autumn about thirty half-standard trees, chiefly Hybrid Perpetuals, and planted them in my little garden. I dug holes about 1½ ft. deep, put a bucket of stable manure in the bottom of each, planted the trees, staked them, and (regarding the culture of Roses as a mysterious affair, not to be rashly undertaken) waited anxiously for the result. I have been, however, rewarded for the little trouble I took with a good display of Roses, both as regards quantity and quality, without a single failure. Either, therefore, my experience is exceptional, or nothing is easier than to grow Roses. One of my trees, Madame Bérard, a Tea Rose, deserves special remark; it was one of the first to bloom, and kept up all the summer and autumn a continuous display of exquisitely-tinted flowers. Certainly no Rose in my limited experience can compete with this one.—S. C., *Dorset.*

Crimson and Pink China Roses.—These are, perhaps, the most continuous flowering varieties of the Rose that we possess; for months they are continuously a sheet of bloom. I am well aware that the individual blossoms are not to be compared with those of Hybrid Perpetuals, but for isolated spots in pleasure grounds I feel sure that beds of these old-fashioned Roses will well repay the minimum of attention which they require.—J. G.

Roses in Autumn.—The beautiful collection of Roses we have seen exhibited by Messrs. Wm. Paul & Sons from time to time in late autumn serve to show the advantages gained by planting suitable kinds in every available space close to greenhouse walls and similar places. From such positions as these the blooms alluded to are cut. The plants cover the low bare walls during summer, and in autumn yield an abundance of buds. The best kinds are Safrano, Souvenir de la Malmaison, the beautiful snow-white Niphetos, so much valued in London markets for bouquets, Isabella Sprunt, Marie Van Houtte, and several other good autumn-blooming kinds.

ANSWERS TO QUERIES.

3834.—**Planting Roses.**—Dwarf Roses should be procured and planted at once. The ground is now in excellent order, and if longer postponed poor plants only will be procurable from the Rose nurseries, as there is a great demand this season for all sorts, owing to the ravages of the past two severe winters. Poor plants give no satisfaction, and frequently dishearten a young beginner; too much stress, therefore, cannot be laid upon this point—to apply early and thus get good, strong, well-rooted plants. If possible, give the Roses a bed or beds to themselves apart from other flowers. Prepare the ground by trenching 18 in. deep, mixing with it some good half-rotten stable manure. In planting, the point of union of the Rose with the stock should be 2 in. below the ground; let soil, not manure cover the roots, and keep the points of the roots downwards, spreading them out as much as possible. Cut away all damaged roots, and shorten any which are too long, preserving intact all those small and fibrous. A good distance apart for the plants will be found 20 in. to 26 in. each way. If the ground is clayey, the Roses budded on the Brier will do best, as it is the natural soil of the stock; on the other hand, Roses budded on the Manetti stock will be the best for light lands, especially if sandy or mixed with gravel. Most Rose growers can supply the best sorts on either stock, but the Manetti is by far the stock mostly cultivated and budded. Shorten the long shoots about a third, to prevent rough winds disturbing the tree, as the roots will move before the severe weather arrives, and thus be more likely to do well next season, getting partly established at once. Thus done, all will be safe until March, when the plants should be pruned, but of this operation there is time enough to speak. I hope to give some few ideas on this point as the season for pruning arrives. As regards the best sorts of Roses for general purposes, that is, suitable for garden purposes, small amateurs, and the lover of a small garden generally, I append a list which will be found to give satisfaction, and, if properly treated, they will grow and,

Hardy Azalea (A. mollis).

weather permitting, unfold their lovely flowers, to delight all with their fragrance and glowing colours. *White, blush, and rose-coloured*—Boule de Neige, Baroness Rothschild, Comtesse de Serenyi, La France, Marquise de Castellane, François Michelon, Hippolyte Jamain, Mabel Morrison, and Madame Lacharme. *Carmine and red*—John Hopper, Edouard Morren, Dupuy Jamain, Jules Margottin, Alfred Colomb, Beauty of Waltham, Mdlle. Annie Wood, Duke of Edinburgh, Mons. E. Y. Teas, Duc de Rohan, Duchesse de Caylus, and Star of Waltham. *Crimson and maroon*—Charles Lefebvre, Fisher Holmes, Dr. Andry, Senateur Vaisse, Madame Victor Verdier, Ferdinand de Lesseps, Prince Camille de Rohan, Abel Carrière, Pierre Notting, Sultan of Zanzibar, and Jean Liabaud. *Climbing Roses*—Gloire de Dijon (best of all) and Cheshunt Hybrid, both perfectly hardy and good growers, the former flowering early and late. Most of the Hybrid Perpetual Roses, of a vigorous growth, make capital pillar or wall Roses. Tea Roses and Noisettes are not, generally speaking, hardy enough to recommend for ordinary garden culture requiring protection from frost and cold winds. Before planting any of these the habit and constitution of the varieties should be carefully studied. It only remains to be stated that, to grow Roses to perfection, pains and personal attention are absolutely necessary, both as regards head and hands, and to those so devoting themselves to this work I can safely promise a rich reward in the way of a delightful and useful recreation. I wish many more of our friends having suitable gardens and leisure would try it.—William Walters, *Burton-on-Trent.*

3830.—**Florists' Polyanthus.**—In reply to the query of "H. S.," I am glad to be able to inform him that the varieties named by "A. D." may be found in the catalogue of hardy plants, &c., sent out by William Clibran & Son, of the Oldfield Nurseries, Altrincham. The prices range from 9d. to 2s. 6d. each, except Buck's George 4th, which is 7s. 6d., and is stated to be very scarce. I believe Lancashire has always been a noted county for the cultivation of the Polyanthus. As regards the scarcity of fine varieties, in my opinion it is one of the results of the "bedding-out mania." When this system first commenced, numerous charming plants became at once neglected. The demand for them in a great measure ceased, and therefore growers for sale no longer found it to their interest to devote so much attention to such subjects. Happily, the taste for old-fashioned flowers, like the Auricula, Polyanthus, Carnation, and Picotee, &c., seems to have revived during the past few years, and the only drawback to their universal culture seems to be the high price charged for some of them, more particularly the Auriculas. I cannot help thinking that florists would do a brisker trade in these charming plants if the prices were reduced some what; 2s. 6d. to 5s. each for alpine varieties is a price which comparatively few can afford to give. It may not be out of place to mention here that the beautiful old double Wallflower of the blood-red and purple varieties seems to be almost lost, or at any rate very scarce indeed. I find that the very few firms who still retain them in their catologues are not always prepared to supply them when ordered. No doubt they still exist in a few secluded country places where some of the "old school" have never ceased to cultivate their favourites, and carefully protect them during the severe winters which are destruction to these double varieties, but eighteen years ago I have seen them in gardens by scores.—Burns.

3833.—**Flowers in Winter and Spring.**—The best plants to keep up a supply of bloom in a greenhouse from Christmas onward are Chinese Primroses of various colours, Cyclamen, Camellias, white and coloured, Erica hyemalis and gracilis, Deutzias, Genistas, Echeveria retusa, to be followed by Cinerarias, Hyacinths, Tulips, Himalayan Primroses, Polyanthus, and common Primroses, single and double Violets, Myosotis, and other hardy things, all of which will bloom freely in a greenhouse where there is but a moderate amount of heat. It is too late to sow seeds of plants to flower early in the spring; there is not time to get the plants into bloom. The proper time is about July and August, when several hardy annuals may be sown, such as Silene pendula, Saponaria calabrica, Nemophila insignis, Pansies and Violas, Limnanthus Douglasi, &c. If seed of any of these things were sown now under glass, they would not bloom before June. All the earliest spring-bedding plants, such as Daisies, are not raised from seed, but increased by division.—A.

3834.—**Planting Roses.**—Roses may be planted now in the open ground, and a climbing Rose may be planted in the greenhouse now or almost at any time if turned out of a pot. Those planted out under glass need as they get established plenty of water, and occasionally a top-dressing of short manure. By bush Roses, probably such as the old common and crimson Chinas, Damasks, Scotch and Persian Briers, &c., is meant. These may he obtained from a Rose nursery under the above designations. Tea Roses are rather too tender to grow as bushes, but good Hybrid Perpetuals on their own roots, such as John Hopper, Louis Van Houtte, General Jacqueminot, and others make good bush plants. Ask a nurseryman to send you a proper selection for the purpose you require.—A. D.

3839.—**Plants for Rooms.**—Of flowering plants suitable for a cool room to bloom now the best are Chinese Primulas, Cyclamen, forced Deutzias and Genistas, early Cinerarias, Epacris hyemalis (white and lilac) and gracilis (red). Plants that bloom now and through the winter without artificial heat are few indeed. In the summer there are plenty of things that may do well in a room window with the aspect named, Pelargoniums, Fuchsias, Musk, Creeping Jenny, Yellow Calceolarias, Petunias, Azaleas, &c., all bloom freely in the summer almost anywhere. Of course too much must not be expected from plants in a room, as the conditions are very different from those in a greenhouse.—A.

3840.—**Wintering Ferns.**—Provided the room in which your Ferns are does not admit hard frost, the plants should be none the worse for losing their fronds now. It is but the natural rest the plants have when not kept in strong heat. A temperature of about 50°, which is certainly very warm for the winter months, will keep all the greenhouse kinds green and growing. The best soil is half loam and half sandy peat. It would be best, perhaps, not to plant out in a case at present, but leave till the spring. The damper air of a case may be prejudicial to plants that are now at rest.—D.

3818.—**Treatment of Vallota, Amaryllis, and Agapanthus.**—The Agapanthus and Vallota should winter in a cool structure, not depriving them of light, and giving enough water to keep the foliage from shrivelling. The Vallota flowers most freely when the soil is crammed with roots, so that if the plant is in a 6-in. pot there will be no need to repot; otherwise it may be shifted in April in a compost of peat and loam, keeping the bulb well up above the level of the soil. If it is not desired to fresh pot, the necessary amount of luxuriance may be obtained by watering with weak liquid manure once or twice a week. The best way to administer water in the winter is to stand the pot in a saucer and let the soil absorb the necessary amount of moisture. Sometimes in watering in the ordinary manner the surface soil gets too wet and decay sets in at the base of the bulb, but by the plan recommended this danger is obviated. The African Lily (Agapanthus) is a gross feeder, and should be shifted in March into a rich compost of good loam, leaf-mould, and decayed manure, pressing the soil in very firmly round the roots. This plant likes plenty of moisture at the root when growing, and as soon as the pots get full of roots, liquid manure, such as guano water, should be given at least twice a week. The Amaryllises may be stored away in any corner or under a stage for the winter, bringing them into the full light in March. Give them a top-dressing of free rich soil, but be sure and not give a drop of water until the flower-buds appear; then water gently until the plants are in full growth, when copious supplies should be given. The plants may also be shifted as soon as the flower-buds are seen into a good compost of loam, leaf-mould, and rotten dung, using it in a moist, but by no means wet state, and carefully watering until growth becomes lively. If so desired, the Amaryllis can be forwarded into bloom by placing the bulbs in gentle warmth at the beginning of the year.—J. C. B.

3842.—**Cropping a Kitchen Garden.** You have done rightly in casting up the soil into rough ridges, and the best way will be to let it lay thus until sowing time arrives. We see no reason why the greater part of the vegetables commonly grown in gardens should not succeed in the situation mentioned. As to the time of sowing and general culture, we must refer you to the calendar of operations given weekly in this paper, and you will also find from time to time cultural articles bearing on your wants. If fruit is to be grown, both Gooseberries, Currants, Raspberries, and Strawberries, may be now planted, and a few Broad Beans and early Peas may be sown in the warmest and driest situation in the garden. The boxes may be utilised early in the spring for sowing Lettuce, Mustard and Cress, and Radishes, and in another year they would prove an excellent shelter for Brown Cos Lettuce and Cauliflower plants.—J. C. B.

3829.—**Climbers for Trellis.**—Any of the Ayrshire or evergreen Roses, such as Ruga, Dundee Rambler, Félicité Perpétué, and Adelaide d'Orleans, would succeed. They are vigorous growers and perfectly hardy, resisting with impunity the most severe frost. Clematis Jackmani and rubella would form, by reason of their rich colours, a pleasing and effective contrast to the pale tints of the Roses. We would also plant a Gloire de Dijon Rose, giving it the best place, and you might introduce, if there is space enough, a Dutch Honeysuckle. The moisture at the roots will just suit the Clematis, which must be cut down to within 4 in. of the soil every year, the month of March being the best time for so doing.—J. C.

3844.—**Culture of the Artillery Plant.**—This is a very easy plant to grow. During the winter it requires a temperature of from 50° to 55°, and delights in a moist atmosphere throughout the summer. A good compost for it consists of half loam and half leaf-mould and peat in equal proportions, adding thereto about one-sixth of the whole of silver sand. Shift in April, and shade from bright sunshine until the middle of September, when it should be freely exposed to the sun's influence. Water moderately until the pot gets full of roots, and then water more freely. During the winter water only when the soil is dry.—J. C. B.

3837.—**Hardy Passion-flower in Greenhouse.**—As your plant has made good growth, it will, in all probability, bloom well next year. If the pot is full of roots, it may be shifted about the middle of March into the next sized pot, otherwise a top-dressing of some concentrated manure will suffice. In order to get this climber to flower well, it should be fully exposed to the light, and should get plenty of air when growing, giving abundance of water in hot weather. Pruning consists in shortening back the shoots to about two-thirds of their length. This should be done at once.—J. C. B.

3870.—**Tomato Growing.**—I have grown these both in pots and in borders under glass very successfully this year, having had 800 to 1000 fruit from about thirty plants in 12-in. pots, in a cold pit without any artificial heat. One of the great secrets in Tomato culture which no one seems to mention (if quantity of fruit is required) is to confine the roots, say if planted out, by putting slates under and all round the plant in order to stop the root spreading too much. When well established use weak liquid manure water twice or three times weekly, and allow only three shoots to grow, keeping all other wood thinned out, and at ripening time cut away most of the leaves. I only used three kinds, viz., Conqueror, Orangefield, and large Red, and find these to be the best.—J. R.

3843.—**Converting Old Lawn into Vegetable Plot.**—The process of bringing a stiff clay into a thoroughly free mellow condition must be a work of time, for it is only by the yearly addition of ingredients of a light and porous description that the close, plastic nature of the clay can be overcome. The first thing to do, where the natural staple is heavy and retentive, is to throw it up into high rough ridges, not breaking the lumps, but leaving them as large and entire as possible. This operation should be carried out in the autumn, before the soil has become drenched by rain; but where it cannot be done thus early, a frosty time should be chosen, just when the surface-soil has become sufficiently firm to walk upon comfortably and before it has got too hard to admit of the free entry of the spade. Allowed to lie thus ridged up until spring, frost and wind by that time

will have so purified it, that it will be so far in a fit state for the reception of plants or seeds. During the winter any materials that it may be desired to incorporate with the soil should be brought together in readiness for use when the time arrives for sowing or planting. Burnt earth, charcoal-dust, wood-ashes, leaf-mould, and river sand are all excellent for the purpose; and if anything like a coat of 4 in. to 6 in. of any one of these ingredients can be applied, not only will the fertility of the soil be much increased, but it will lose a great deal of its close, retentive nature, and will be brought into and remain in a friable and workable state. When a piece of ground is required for planting, choose a dry day, and pull down the ridges, breaking all lumps, which should then crumble to fragments at the touch of the fork. Then apply the dressing of light soil and the manure, and fork it all well in, thoroughly mixing the various ingredients together. Any lumps which may not have become sufficiently pulverised to admit of their being broken by the fork should be brought to the surface, where sun and air will dry them out and sweeten them, so that the first shower of rain will cause them to crumble to pieces when touched with the fork. In this manner a good foot of free mellow soil will be at the disposal of the grower. In the case of newly-turned-up pasture the best way will be to crop it the first year with Potatoes, as the earthing up and digging will do much towards bringing the soil into a friable state. We would not plant early, but allow the ridge to remain until the middle of March, planting about the first week in April. If the whole of the plot cannot be dressed the first year do a portion of it. In the course of two or three years a stubborn piece of clay may be converted into a free, workable body of soil. I should add that drainage is of great importance in the case of heavy lands, and if only two rows of pipes can be laid through the piece of ground in question, it will be much improved thereby.—J. C. B.

3824.—**Renovating Lily of the Valley.**—The plants are probably suffering from overcrowding and want of good nourishment. The Lily of the Valley revels in deep, rich, light soil, and will not give blooms of good quality unless thus circumstanced. Take up the plants and lay them in carefully if you desire to replant in the same place. The best, way, however, would be to prepare a fresh situation for them. Stir the soil deeply, and if it is of a tenacious nature, add to it some light soil and well rotted dung; if the natural staple is sandy, all that will be needed will be good manure. Select the largest crowns, and plant them 6 in. apart, the smaller ones to be set by themselves. Mulch with manure, and water well in hot weather.—J. C. B.

3842.—**Cropping a Kitchen Garden.**—As I am a resident on the north-east coast, on the opposite side of the river Tyne from Finem Respice, and having a kitchen garden of a quarter of an acre in size, and within a quarter of a mile from the seashore, may I be permitted to give a list of what I have grown during the present year?—Lettuce, Radish, Onions, Leeks, Turnips, red Beet, Celery, Cauliflowers, Savoys, Curly Greens, red Cabbage, Dwarf Beans and Peas, Potatoes of sorts, Rhubarb, and herbs, such as Parsley, Sage, &c. All the above were sown and planted in April of this year, and turned out to be what any one might term splendid crops. Such things as Lettuce, Radish, Leeks, and Cauliflowers might be sown in boxes in March, but for the open ground all such things as are above mentioned should not be sown or planted till the beginning of April.—J. C., *Whitley-by-the-Sea*.

3825.—**Removing Glass from Glasshouses.**—I have found heat to soften old and hard putty, and would suggest an iron bar ⅜ in. square, any handy length, bent in any convenient form, with a non-conducting handle. Make it nearly red-hot, and apply it to the putty (care being taken not to touch the glass), and remove with hacking or chisel-knife. The iron could be made by any blacksmith. A copper bar would hold the heat longer than iron, but is much more expensive.—KIKO.

3826.—**Vines and Rats.**—The druggists are right in exhibiting care in the sale of arsenic, especially in London, where no one is personally known, whilst in country districts it is of less moment, because there the druggist knows something personally of his customers. Moth and Ringesen's rat paste can always be purchased, and this spread upon pieces of bread and placed in the runs generally gets eaten. It is a powerful and effective poison. Some good may be done by working the runs well with ferrets. It is not improbable that if some paraffin were sprinkled in the runs the rats would refuse to come near it, as such a perfume would be to their fine noses very obnoxious.

3841.—**Tropæolum speciosum.**—One of the best methods to transplant roots of the Flame Tropæolum is to lift a quantity of soil and roots in a lump and transfer to where needed. The roots very much less feel the check incidental to transplanting.—A. D.

3822.—**Plants from Stiff Clay Soil.**—Few plants will do better for covering a border in front of evergreens on clay soil than the Periwinkle (Vinca elegantissima), and the variegated form also. The Creeping Jenny will do, so will some of the creeping Saxifrages, also the Grasses Festuca glauca and viridis. For a dwarf smooth covering nothing is better than some of the green Sedums, especially Lydium. Ivies make a capital permanent covering in time, and once established will endure almost for ever.

3835.—**Cineraria Leaves Curling.**—Some Cineraria leaves curl naturally One of the finest kinds, Master Harold, may be distinguished at once by that peculiarity. Cinerarias can hardly want manure water yet unless the plants are nearly in bloom. Make it weak and give to the plants less often. Also give plenty of air in mild open weather.—A. D.

3830.—**Garden Polyanthus.**—The only *bona-fide* trade grower of these choice forms of gold-laced Polyanthus in the south of England is, as far as I know, Mr. R. Dean, Ranelagh Road, Ealing, W., who has most of the best kinds on sale, but I cannot give the prices. Mr. Dean can no doubt give "H. S." full information as to the whereabouts of northern trade growers. Between 1840 and the present time there has been a sad decline in the cultivation of the gold-laced Polyanthus, hence the comparative scarcity of many kinds.—B. S.

3831.—**Holly for Walking Sticks.**—We have found Holly growth of three years old to make the best and most enduring walking sticks. At that age it is both very hard and very tough. The bark should be removed, and the wood allowed to dry slowly before staining. When dried and rubbed well down with sand-paper a coat or two of ordinary painter's staining will colour them, and a coat of varnish will complete the operation.

3820.—**Raspberries on North Wall.**—Raspberries may do very well against a north wall if the summer proves a hot one, but if sunshine is lacking them, the new canes or suckers will not ripen, and no fruit may be looked for the next year. It is of the first importance that these should be ripened to get a crop of fruit, and therefore a sunny position is best. Red and Black Currants will do well against a north wall, and the fruit will hang until October.—A. D.

3766.—**Preventing Tree Stumps from Growing.**—Bore a hole in the centre of the stumps, and pour in a tablespoonful of sulphuric acid.

3700.—**Cost of Greenhouse.**—I built a small greenhouse last summer in the south-west angle of my garden wall, span roof. I paid a builder £4 to cut out and erect all the wood work including door and one course of brickwork. I painted and glazed it myself; I put in the stages. The cost of my greenhouse including a guinea stove is under £6.—OXONIENSIS.

3840.—**Wintering Ferns.**—I should advise "W. J. H." to plant his Maidenhair Ferns in his case as soon as it is ready. The roots must not be allowed to get dry, and frost must be excluded from them. Ferns require a light open soil; a compost of fibrous peat two parts, turfy loam one part, and leaf-mould one part, with a free admixture of silver sand, will suit them well. —STYAN, *Pottemewton, Leeds*.

3651.—**Plants for Rooms.**—I say positively that if "H. R." has gas in his house he need not have plants. I am a gas-fitter by trade, and I speak from experience, that however tight pipes and taps may be, there is a certain amount of escape which will destroy almost every plant except Ferns; at first the leaves turn yellow, then drop off. I have grown plants for many years in my greenhouse, and when one day in the house where the gas was they felt the effects.—E. T.

3825.—**To Soften Putty.**—Dissolve some soda in hot water, and mix with some fresh lime; when slaked it can be applied to the putty with a knife, and in a few hours it will soften the hardest putty.—F.

3826.—**Vines and Rats.**—Get a packet of Kearney's rat poison from Messrs. Kelly, Lower Sackville Street, Dublin, and carefully follow the printed directions sent with the packet, and you will soon get rid of the rats.—A. W. G.

3887.—**Transplanting Sweet Williams**—*Chemah*.—The best times are September, October, March, or April.

3888.—**Warming Greenhouse with Lamp.**—*Chemah*.—An open oil lamp is very injurious to plants.

3889.—**Budding Roses.**—*J. T.*—Get a copy of GARDENING, August 2, 1879, in which you will find an illustrated article on the subject.

3890.—**Grafting Old Fruit Trees.**—*J. T.*—As you know nothing whatever of the operation, you had better get some one to show you the way You will learn more in five minutes than we could tell you in a whole page.

3891.—**Clubbing in Cabbages.**—*Teddington*.—Get equal parts soot, air-slaked lime, and sulphur, and mix with water to the consistency of mortar, and dip the roots of the plants in the mixtnre before planting. A little red lead may be added.

3892.—**Slugs and Snails.**—*Teddington*.—Gas lime should only be applied to the land in winter when vacant. Salt may be used on land free from crops at the rate of 7 cwt. or 8 cwt. per acre.

3893.—**Roses on Walls.**—I have some Hybrid Perpetual Roses (bushes), and have planted them under a dwarf wall facing south. Will they flourish there as wall Roses? or must they be planted out in the open ground away from the wall?—W. B. [They will do very well if nailed to the wall.]

3894.—**Saxifraga longifolia.**—I have this planted in a sloping position on rockwork, facing south. It will not thrive, but decreases in size all the year; what requirements are necessary for its proper culture?—W. B. [Deep, moist, sandy soil and a partially shaded situation.]

3895.—**Potting Ferns.**—*Inquirer*.—You had better do this in February or March. Remove the sour soil from the roots, and replace it with fibry loam or peat and a little well-decomposed cow manure free from worms.

3896.—**Grafting Fuchsias.**—*Inquirer*.—Just when the buds are bursting is a good time The easiest way is to put the plants you wish to graft side by side, and inarch one branch on to the other by paring with a sharp knife a piece out of each branch and uniting them afterwards, binding them with soft bast or worsted. When well "taken," cut off close to the union.

3897.—**Fern Fronds a Pale Colour.**—How is it that the fronds of my Maiden-hair Ferns come up of a pale colour? I keep them at the end of a greenhouse where the glass in summer is painted a pale green. Is it sufficient shade? I allow the fronds to wither naturally, and then cut them off. They were when purchased a beautiful dark green.—E. H. [They want more light and probably more heat and air. Give them a little weak soot water occasionally.]

3898.—**Plants Losing their Leaves.**—I have two greenhouses, one kept at 60° to 70°, the other 50° to 60°. I have several Euphorbia jacquiniæflora and Poinsettias; both are in flower, but the leaves get yellow and drop off, and though they are kept in the warmest house, watered only moderately, I cannot keep a leaf on. I have only had them in a week. I also find that the Gardenias and Azaleas, though only kept moderately damp, have thrown up a kind of white fungus, mouldy in appearance. What is the cause and remedy?—W. E. P. [The Euphorbias and Poinsettias evidently require a little help in the way of artificial manure or manure water. Give them enough at a time to thoroughly soak the whole of the soil. Water given in driblets always brings unsatisfactory results. The Gardenias and Azaleas are probably suffering from this.]

3899.—*Beatrice, N. K.*—We cannot find out what plant you allude to; we do not know one of the name you mention.

3900.—**Insects on Plants.**—*A. H.*—It is scale probably. See article on its destruction in last week's GARDENING.

3901.—**Lichen on Fruit Trees.**—*Mr. C.*—See GARDENING, November 27.

3902.—**Wild Cherry Tree.**—In my garden I have a beautifully-shaped wild Cherry tree about 18 ft. high. What can I do to make it profitable?—R. W. D. [Cut it back and graft it with a good sort; do it at once or early in spring if you can get the grafts. You had better get some one who understands grafting to do it for you.]

3903.—**Tea Roses.**—I have several Tea Roses in my lean-to greenhouse, which ranges in heat from 55° to 75°, they are still flowering, but the leaves keep falling. I should be glad to know how this can be avoided. I do not water heavily, only just keeping them nicely moist. —RANTUT. [You cannot expect to keep Roses always growing and flowering. They are sure to lose some of their old leaves in winter.]

3904.—**Stock for Epiphyllums.**—*Constant Reader*.—The Pereskia is the best stock. Graft in spring after the plants go out of flower, or early in autumn. Firm, sandy, porous soil is the best.

3905.—**Mushrooms in Greenhouse.**—I have a space about 4 ft. wide and 6 ft. long, surrounded with hot-water pipes in a greenhouse; over it is an open stage for plants, so that the drip goes through. Could I utilise the space by making a Mushroom bed? How should it be made if feasible?—B.E. [It would not do unless you slated over the stage to prevent drip, and then it would be extremely doubtful. An outhouse or cellar would be much better for Mushroom growing.]

3906.—**Shrubs in Window Boxes.**—*A Learner*.—Solanums will not succeed during winter in an outside window box. As regards the shrubs not doing well, perhaps you have been imposed upon by the person you bought them from. If you got them from a street hawker turn them out of the pots and see if they have any roots.

3907.—**Golden-leaved Arbor-vitæ.**—*A Learner*. You probably mean Thuja aurea.

3908.—**Planting Tulips.**—*Lover of Flowers*.—Plant any time whilst the weather is open. Bury the bulbs 2 in. in the soil. The bed should be well dug and manured before being planted.

3909.—**Town Greenhouses.**—*Mrs. W.*—You will find articles on this subject in GARDENING from time to time.

3910.—**Pruning Thujas, &c.**—When should Retinosporas and Thujas be pruned? and how are they propagated?—LEWISHAM. [Prune with a sharp knife in March or April. They are propagated from small shoots placed in pots of sandy soil in a close frame or a cool greenhouse.]

3911.—**Zonal Geraniums for the Window.**—When the above has done blooming in early summer, and you want them to bloom in winter, what is the proper treatment?—F. [Stop the points of the shoots; keep all flower-buds picked off, and place in the sun till October, when house in a airy, dry temperature of 50° to 55°.]

3912.—**Preserving Leaves.**—Will you explain how to preserve between paper some few leaves of Australian trees and plants? and are they gummed on?—QUIS. [Put them between blotting or drying paper under a heavy weight; take them out every day, and dry the paper. When well pressed and dry, fasten them on to your mounting paper with small strips of paper and gum.]

9313.—**Seakale.**—*Gloire de Dijon*.—Seakale wants deep well-manured soil. Purchase some young roots from a nurseryman, and plant at once. Do not cut any this season, but let it get well established for next year, that is if you want a permanent plantation. After this you can get stock by cutting off the fleshy roots 3 in. long, and planting them in good soil during winter and spring.

3914.—**Tritonias, &c.**—*Gloire de Dijon*.—They may be potted now in good sandy well-drained soil, and put in a frame or greenhouse, or they may be planted in any warm sheltered position out-of-doors, where a little covering can be given them in spring during severe weather.

3915.—**Liming Land.**—*One in a Fix*.—A good shovelful to a square yard is a very fair dressing; you can

more if convenient. The soot would be better put on in spring a few days before you crop the land. A slight covering will be enough. Both the lime and soot must be well worked into the soil.

3916.—**Club in Cabbages.**—*One in a Fix.*—Sow the seed in firm land, and before planting dip the roots up to the leaves in a mixture of equal parts soot, lime, and sulphur, with a little clay added to make it of the consistency of thick paint.

3917.—**Tarred Fence for Plum Trees.**—I am about to build a hoard fence, and thought of preserving it with tar. Would the tar when dry be injurious to Plums trained over it?—H. H. [Not in the least.]

3918.—**Cyclamen in Windows.**—*Lingden Hazel.*—Give plenty of air, sponge the leaves with tepid water occasionlly, and water at the root when the soil is getting dry. Do not use manure water.

3919.—**Early Potatoes.**—I am going to try to get early Potatoes. I have got a large Cucumber frame and a Vinery, both with heat. The Potatoes I am going to set are Old Ashleaf and Rivers' Royal Ashleaf Kidneys. What sort of soil had I best plant in, and when? and further, what degree of heat will they require? Must they have plenty of air?—W. Jones. [If you can give them a slight bottom-heat by means of a bed of leaves you had better do so. Use light soil free from worms, &c. Plant within 2 ft. of the glass, if a little closer all the better. Plant in rows 1 ft. apart, and 9 in. from set to set. Cut out all the eyes from the sets but one—the strongest. Do not let the temperature fall below 40°, nor exceed 50°. Give plenty of air whenever possible. Water well when growing freely and earth up when necessary.]

3920.—**Raspberries Failing.**—*Globe.*—The culture of Raspberries is summed up in a few words. Rather light rich soil, frequent hoeing, but not digging up the surface, mulching during hot weather, cutting down all old canes close to the ground in autumn, leaving enough young ones made during summer to fill their places.

3921.—**Aspidistra Turning Yellow.**—*Mrs. W.*—You must indeed treat it badly, for we know of no plant that will stand so much rough usage as this. Give it water when it is dry, and sponge the leaves occasionally. If it is pot-bound give it a little manure water or artificial manure.

Second Volume of Gardening.—*Hernhut.*—The second volume commenced with No. 52.

Brass Syringe.—*M. S. M.*—Apply to any seedsman or ironmonger.

Summer Flowering Chrysanthemum.—*J. J.*—From any good nursery.

Moss on Fruit Trees.—*Canadian.*—See article in Gardening, November 27 last.

Balsam Seeds.—*F. D. S.*—From any respectable seedsman. Consult our advertisement columns.

J. O.—Try good putty.

Names of Plants.—*G. A. R. D.*—Pernettya mucronata.——*Mary.*—Apparently Genista hispanica; it will grow in any good soil.——*F.*—Diplacus glutinosus, a hardy plant, or may be grown in pots in frame or greenhouse; flowers orange.——*W. R. T.*—You probably mean the Belladonna Lily (Amaryllis Belladonna).——*Kettering.*—An Anthurium of some kind, but we cannot tell which without flowers.——*Flora.*—Euonymus radicans variegatus.

QUERIES.

3922.—**Gravel for Walks.**—Will some one give me some information about the best gravels to use for making walks? It is daily more and more apparent to me that the paths of a garden are one of the most important parts both for utility and appearance. I live in Holderness, not very far from the sea, where we have plenty of sea gravel; plenty of gravel of a chalky nature and plenty of ashes are procurable. We have no difficulty in getting ballast for the bottom of the walks, as the clay, if burnt, forms a very good dry bottom, but it is the surface of the walks that is our difficulty. The gravel from the seashore is good in colour, but it will not bind, and is constantly kicking about on the beds, and is trodden on to the Grassplot, where it spoils the mowing machines. The gravel from near the chalk is soft, and after a frost runs almost like clay. Ashes look funereal and spoil the prettiest garden, and there is the same objection to asphalte. There are gravels which combine the hardness of sea gravel with a good yellow colour and a power of setting quite hard, so that in almost all weathers they will bear walking and wheeling over. If any reader can refer me to any place near here where such a gravel can be met with, I should be very grateful, as it has long been a difficulty with me. I have heard of there being such in the higher parts of Lincolnshire, but find a difficulty about how to verify what I hear.—S.

3923.—**Improving a Lawn.**—I have a lawn about 50 ft. by 30 ft. which I want to improve, as the quality of turf (laid last year) is not good. Will any reader instruct me how to proceed and give me the names of Grasses most suitable? also whether it would be ready for use for croquet next summer.—O. C., *Wimbledon.*

3924.—**Butterfly Tulip.**—Can any reader inform me the proper soil required for growing Calochortis luteus (Butterfly Tulip, yellow), and the mode of treatment and time of planting?—A. C. H.

3925.—**Salt as a Fertiliser.**—Will any reader inform me what weight of salt per rod could be safely applied to land as a fertiliser? Also the weight of salt that should be mixed with an ordinary bag of soot to form a compost for Potatoes. The soil to which it is to be applied is rather dry and porous.—M. T. W.

3926.—**Orange Trees.**—I shall be very much obliged if any reader will tell me how to grow Orange trees. I planted a seed three years ago, and it seems to have stopped growing. Is it likely to bear flowers?—Mervyn.

3927.—**Pruning Roses.**—I have a large Gloire de Dijon Rose trained over the front of my house, with a southern aspect What system of annual pruning ought I to adopt in order to obtain the most bloom?—F. T M.

3928.—**Keeping Chrysanthemum Blooms.**—I am told there is a method of keeping Chrysanthemum blooms in a dark cellar for several months, after which period they will apparently be as fresh as when first cut. Will a reader kindly tell the secret if such there be?—A Subscriber.

3929.—**Raspberries Blighted**—Three years ago I noticed in one piece of my Raspberries about forty roots, the young canes of which were coming up weak, knotty, yellow, and bushy headed; they only grew 1 ft. to 18 in. high—useless. The next season three other places, some 30 yards distant between each were similar. The fruiting canes cut to 4 ft. (fruit hard and valueless); some roots are between others that are growing with canes now 10 ft. I noticed a few black aphis around the roots. I have had more than thirty years' experience, and grow five acres of the above myself, but have never seen the same before; neither have other growers of 200 acres with whom I am acquainted. I manure them well, and every attention is paid. Can any one inform me what steps to take to prevent the disease spreading? It shows in the early spring directly the canes for the next season are coming through the ground.—T. W. B. B

3930.—**Chrysanthemums for Pots.**—Will you favour me with names of about a dozen large-flowering Chrysanthemums suitable for pot culture? stating their colour and character; also information respecting the same number of Pompones.—H. F.

3931.—**Garden Walks.**—In my part of the country there is no gravel, but only sandstone, which makes but a bad material for winter use. The custom is to use asphalte paths, but the colour of asphalte paths is so funereal that even when sprinkled with white sand it is by no means a good equivalent for the pleasant look of the London gravel. Can any one inform me of any method by which one may obtain a better colour. Is there any cement of a reddish hue which could be mixed with a broken sandstone to form a permanent path? Or would broken brick or burnt clay on the top of asphalte answer? A satisfactory method of getting garden paths at once durable and pleasant in appearance would be welcome to Venetian Red.

3932.—**Gas-lime in the Garden.**—I shall be thankful for any information with reference to the application of gas-lime to vegetable garden infested with earth worms, slugs, and caterpillars. I have given it a dressing of salt, but am informed that gas-lime is more effectual, and the soil being deficient in lime I am anxious to try it; but as it smells as if it was saturated with gas, I hesitate about doing so, not knowing what effect it would have on the vegetables now in the garden, and the seeds which I shall sow almost immediately and in the spring.—Lumbricus.

3933.—**Unfruitful Pear Trees.**—I have two Pear trees, one of which each year bears blossoms, but never any fruit. The other has never had even blossoms on it; both make pretty well of wood. I have cut off some of the principal roots, and still but little change has taken place. Can any one suggest the cause and cure?—H. J.

3934.—**Plants for Clayey Bank.**—At the foot of a small croquet lawn I have a bank facing north. The soil is stiff, and I have drained the lawn to the bottom of the bank, so that the lower part will always be both stiff clayey soil and wet. I have filled into the bank a couple of loads of old tree roots, and should be glad to know what best to buy to plant among the roots in such a soil and situation? Some of the roots are fine ones; projections 4 ft. to 5 ft. long.—J. Y.

3935.—**Planting Flowers.**—I have a good bit of flower garden, but lately I have had very little time. I have therefore had to trust to a jobbing gardener. The result is a minimum of flowers with the maximum of expense. This I want to avoid in future, and shall be glad if I could get a list of flowers and when to plant them, so that I can expect a fair succession of flowers and keep "jobbers" in order.—H. V.

3936.—**Fragrant Roses.**—I should be glad to have a list of twelve of the most fragrant Hybrid Perpetual Roses.—R. T. B.

3937.—**Secateurs, or French Pruning Shears.**—I bought a secateur about two years ago, and I should be glad if any one would tell me if they bruise the wood or do any harm to the tree?—James Bentley, *Burnley*

3938.—**Insects in Acacia Tree.**—I have an Acacia attacked by grubs in the fork and where branches have been cut off. Can anything be done for it?—Lewisham.

3939.—**Wireworms in Pots.**—Can any reader inform me as to the best means of destroying wireworms in pots?—H. E.

THE HOUSEHOLD.

Preserving Eggs.—1 gal. of unslaked lime fresh from the kiln, 4 oz. salt, 1 oz. cream of tartar, sufficient water to be poured on these ingredients till it becomes the thickness of cream, and will swim an egg. It must be quite cold before being put to the eggs, which should be packed very close and without a crack, and quite fresh. As the liquor wastes, it may be filled up with salt and water. The eggs must be always kept covered up with the liquid. To be put into an earthen pipkin, holding three score eggs.—D.

—— Put fresh laid eggs into a wire net, and immerse them in boiling water for forty or fifty seconds, and they will keep for months.—Delta.

To Pickle Vegetable Marrow.—Peel and take out the seeds of one large Marrow, cut in small dice, sprinkle with salt, and let stand 12 hours. After which get 2 quarts best vinegar, 1 oz. ground ginger, 1 oz. Tumeric, a few Chillies, a little Cayenne, two Shallots, 12 oz. loaf sugar. Boil these together for 10 minutes, then take out the Shallots and put in the Marrow dice, and boil for 20 minutes. When cold ready for use.—J. W., *Berks.*

Zinc Boilers for Brewing.—Can any reader inform me if zinc boilers will answer for brewing purposes? if so, whether hard water or soft is to be used?—A. B.

Malt Vinegar.—Can any one give me a recipe for making malt vinegar?—A. B.

GARDENING ILLUSTRATED.

VOL. II.—No. 94. *SATURDAY, DECEMBER* 25, 1880. PRICE ONE PENNY. REGISTERED FOR TRANSMISSION ABROAD.

THE PEARLY ALOE.

(HAWORTHIA SUBULATA.)

As several of our correspondents have lately sent us pieces of this plant to name, we give a few particulars respecting it. One of the most ornamental of the large tribe of Aloes is the Haworthia subulata, generally called Aloe margaritifera, or Pearly Aloe, of which the annexed is a representation. It has a very short stem and leaves, which are flat above and convex below — in short, triangular in shape and rounded towards the tip. They are covered with a number of white, horny tubercles, which resemble pearls, and give the name to the species. The flowers are greenish, with whitish lobes, marked with a green line, and are grouped together in a terminal spike. The beauty of this Aloe, or Haworthia, however, resides in the leaves, the flowers being, comparatively speaking, insignificant. It is by no means difficult to grow, nor are any of the genus to which it belongs. The best soil for it is a mixture of three parts loam and equal parts of leaf-mould and sand, and it likes good drainage and partial shade in a cool greenhouse. It is often grown in windows with success, and although not pretty, it is exceedingly interesting. It requires but little water, especially during winter, and is well suited to a sunless window. The leaves should be sponged occasionally to keep them clear of dust.

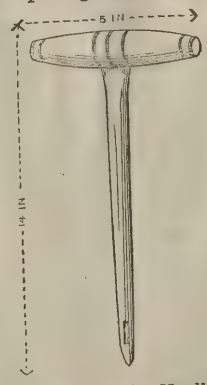
PEARLY ALOE (HAWORTHIA SUBULATA).

LILIES.

OF the many Lilies I have to deal with, none are more particular in regard to soil and situation than L. auratum, the bulbs sometimes dwindling away and disappearing in the most mysterious manner possible. Happening to have them in different situations, I soon found out the cause of this, or, at least, to me, what appeared to account for it—dryness at the roots, arising from the plants growing in an open, exposed position, where the sun shone with full force on the ground around them. In every instance where this occurred the stems were always shorter, and came considerably weaker than others in soil that sloped to the north, or received shade from such shrubs as Rhododendrons, whose roots do not ramble far to rob the ground of its moisture. If we examine the lower part of the stem of a Lily we shall find that when in a young state they begin to emit a quantity of roots around their base, which roots, of course, are intended to forage for them and afford the requisite support to the flowers. It must be obvious, therefore, if these feeders be dried up, or suffer from lack of moisture, that the tops have to draw the whole of their sustenance from the bulbs, which tax on their energies prevents the formation of others to supply their places the following year. This would necessarily occur with any growing where

the surface-soil became parched from the heat of the sun, and therefore any that are at all exposed should have a mulching of some non-conducting material or other, such as half-rotten leaves or very mild hot-bed manure, so as to intercept evaporation. This, with a good watering or two during the active growing season, and when the blooms are showing, will be found of the greatest assistance to them. Although Lilies are such moisture-loving plants at a certain time of the year, anything approaching a wet, stagnant condition of the soil is fatal to them, and more especially is this the case during winter, when they are in a semi-dormant state, as then they take up water slowly. The best way before planting is to thoroughly trench the ground by breaking it up to a good depth, and when doing so to work in plenty of peat if it can be readily got, or if not, a liberal dressing of leaf-mould in lieu of it. A bed or border so prepared will grow any of the kinds well, but with many of them it is a great help if holes are dug out where the bulbs are to be placed, and filled in with rough fibry peat and sharp clean sand, a mixture that is highly congenial to them, and keeps them clean and free from decay. In all cases where peat is not used the sand should not be omitted, as a handful or two of it placed around each cuts off their contact with the moist earth that would otherwise press too closely about them. Where it is intended to grow Lilies in shrubbery or herbaceous borders, in isolated patches or groups, the same kind of preparation may readily be carried out, only the holes dug for them in that case should be made to hold at least a bushel of the mixture above referred to, as then their well-doing will be a matter of certainty. The only natural soil I have ever seen them succeed in in a really satisfactory manner is a greasy, moist sand, in which they grow with great vigour and increase at a rapid rate compared with what they do when not so circumstanced. I have noticed that most of the imported bulbs of L. auratum are coated with the same kind of soil, thus showing that in Japan, where they must grow in immense quantities, the soil they are found in is of a similar nature. As regards the time of planting, the earlier it is done in the autumn, after the leaves and stems are ripe, the better, as immediately these die down large fleshy roots at the base of the bulbs begin to form, and it is almost impossible to interfere with them later on without bruising or damaging these to some considerable extent, but they are very often planted or potted in spring. Such as come from a distance or have been long out of the ground are destitute of these feeders, and every day's delay in planting detracts from their strength, as they are then living, as it were, on themselves, instead of drawing their supplies from the soil. The proper depth at which to place the bulbs is about 6 in. below the surface, or even a little more than that for the large strong growers that require so much extra moisture. In potting, however, it is much the best way not to cover them deeply, but to leave space to top-dress with large lumps of soil as the shoots progress, and these they seize hold of greedily and derive additional strength therefrom. Potting, like planting, should be done early, and the ball disturbed as little as possible, at least that portion of it below the base of the bulbs in which the large fleshy roots are embedded. That on the top will break away with the old stems and leave the crowns bare, among which some silver sand should be scattered, so as to work in and fill up the interstices among the scales. For pot culture there is nothing equal to a mixture of rough, fibry peat and loam in about equal proportions, through which the roots of the Lilies run easily and water percolates readily. Any cold frame where there is a firm, hard floor of coal ashes to place them on answers admirably for their winter quarters, as there they come gradually on, and are in every way better than they would be in a house far from the light and air. S.

A Useful Packing Needle.—The little implement, of which the accompanying is an illustration, is commonly used in Covent Garden Market and by many nurserymen when fastening up baskets or hampers. It is far more effective than the old-fashioned packing needle, inasmuch as the operator has greater power over the tool than he would ever have over the old-fashioned needle. It consists, as will be seen, of a flat piece of wrought-iron or steel, inserted in a wooden handle, and is exceedingly convenient not only for lacing wicker baskets, but also for opening small boxes of fruit or



Useful Packing Needle.

flowers. It can be made on the shortest notice by any blacksmith, and the manner in which it is used will be readily suggested by a glance at the sketch. The handle may also be made of iron or cast-steel if desired, and made to serve as a hammer.

Horticultural Buffoonery.—Mr. Shirley Hibberd has pleased himself with parodying my leaflets, and publishes a number of cuts, showing trees on their end, &c. I only allude to this gentleman from his now repeated attentions, and advise him, he being so fond of buffoonery, to turn to his own books, where there is the richest stores of material in that way that have ever been seen in books published on horticulture. I have long passed by those rich stores content that where a man does any useful work his foibles and his follies should be passed by; but when he is actively seeking a text to illustrate the most puerile attempt at fun that ever appeared in print, it may not be out of place to invite him to turn for a few texts to a book called "Rustic Adornments." This is extremely rich in the pictorial element, particularly in subjects for "Homes of Taste!" He invents trees turned upside down, for me. I should only have to literally copy and republish some of the very striking designs embellishing this and other books of his (and deliberately recommended for adoption) to cause a great deal more hilarity in the gardening world than anything recently published. The man who hangs bricks on fruit trees to induce them to fruit, and who recommends putting a tile under every Potato root, offers, apart from his illustrated books, an easy mark for those who would care to follow up his little incursions into the region of parody. He is a toothless wolf now, and recent events in the horticultural world appear to have soured him and others. But drawing the canine teeth does not purify the heart.—J.

MY COTTAGE GARDEN.

(Continued from p. 499.)

When I first took possession of my garden, with more haste than ultimate speed, I commenced a reform after my own fashion. One naturally has a desire to cultivate the flowers or vegetables one likes best; there were some old stools of Phloxes, a bed of Pansies of the old sorts, pale blue, lilac, &c., a variety of Roses on their own roots, the old Cabbage Rose among them, a variety of tubers and perennials, almost all of which I dug up and threw away; fortunately, some of them declined banishment, notably a patch of the Feather Hyacinth, and the Pansies persisted in coming up; in short, all those plants that delight in a moist situation refused to quit. I at that time paid no attention to their wishes. I had a preference to the Dianthus tribe, especially Carnations and Picotees, Stocks, Zinnias, and several annuals that delight in dry situations; I therefore began with Carnations Pinks, Indian Pinks, and others before mentioned. Alas! I was wrong altogether, but it was a year or two before I discovered my error.

Now, one of the chief reasons of failure was unsuitability of situation, not unsuitability of soil; that is light and rich and would grow anything, but a very short distance below, water may be found that is in the gravel about three spits below. All this is a vast encouragement to vermin; slugs, snails, and caterpillars delight in moist places; hence, these made short work of all the Dianthus tribe; and in wet seasons Carnations that had eacaped the slugs rotted at the base. I endeavoured to meet these obstructions by soot, lime, and all the devices so well known by growing in pots—endless trouble where you want a show of hardy kinds in the borders, and to do so are obliged to sink the pots in the ground. As to Roses, the garden suits them very well, and the few I began with were standards, but I have found that the moisture below only encourages the growth of the Brier shoots, so that in a couple of years they failed also. I have discarded standards for a few or their own roots, and a fine Maréchal Niel only lately planted is growing as fast as a Rose can grow. Besides that, I have a Baroness Rothschild, which seems to me to be the finest Rose of all the new kinds, so that Roses do very well; at the same time I do not care for more than two or three. The Rose most adapted to a cottage is the China; it grows almost anywhere, it may be trained as a climber, and may be made to bloom at any time with a slight check and the application of a little manure.

It will now be perceived that a return to the old plants and flowers was inevitable; therefore, the bed of Pansies increased, and sometimes they are in great force. I have most of the first-rate kinds among them; the International, one of them a rich plum colour, is the finest I have ever seen. The treatment of Pansies in the southern counties requires modification as compared with some accounts given in Gardening Illustrated. The chief sowing should be the middle of September. If sown in August they come on too fast, and by planting out time are weak from being crowded in the seed-pans. I have sown, however, at all times with success, and have sown in spring, but it is not easy to save the young plants in summer, even though they be well shaded. I have had individual plants two and even three years in the same place of the old sorts, but the Pansy has become by extreme cultivation a much more delicate flower than formerly. Some of the notices of them in Gardening Illustrated have proved valuable, and I have availed myself of them. I have also replaced the Phloxes and added Pentstemons; both delight in the situation. Having but limited room, there are only three or four of each. Both grow to immense plants, especially the Phlox. I have four colours: crimson, salmon, white with carmine eye, and white. Clematises also are very healthy.

Being resolved about having Carnations, I had a small house put up for them 12 ft. by 12 ft., where I can have about 20 plants. These are both in the ground and in pots sunk in the ground; the house has no stage, it merely covers the plants; and I began with the French Perpetuals. The same plants are in their third year, and have been in summer masses of bloom. They will not last another year, but measures have been taken to replace them with Perpetual Picotees. They look very well yet, but winter

has not done its work, and I hardly think they will be worth going on with. I have not decided whether they do best in pots or in the ground; the chief care with them is to give as much air as possible, or they draw very rapidly; not to give much water in winter. A top dressing of old manure is almost sufficient to keep the ground moist, and above all to keep away slugs by dusting all round the plant with Tobacco powder. As to the soil, it had at first a barrow-load or two of fine yellow loam from a neighbouring forest and plenty of old manure; these appear sufficient. There is a single shelf in this house with a few hardy greenhouse subjects; to have more delicate kinds would not suit the Carnations. There are three tuberous Begonias (pink, scarlet, and orange), four Primulas, one Lantana, several Fuchsias, a Coronilla, a Gazania, a Schizostylis now in bloom, and these agree well with the treatment, which is door and ventilator open as much as possible, and no artificial heat.

Besides flowers, I have in my garden two stands of bees, and sometimes have a dozen stocks, but the last year or two has played sad havoc with them, and the wax moth has proved very destructive, as it does when they are weak; they have every advantage of situation, for up the river they have clear ground for miles, without a house visible.

Now for the moral of this simple history, and I have found by experience the truth of it. When you come into a strange garden, do not hurry to discard the flowers you find in it, and also let your first care be to find out what will grow best in it. W. T.

Dorset.

NOTES ON PLANTING.

The ground has been well prepared; the manure, the soil, the elements which compose them, are all about to work together, to combine, and to act, and the trees are to find for their roots a comfortable bed. Do not be in too great a hurry; let the soil settle down for a month at least, and do not plant until then. Make your arrangements, however, so that the planting may not take place later than the middle of March, but before that date, if convenient. If the soil is not ready by that time, and if the ground is not in proper condition, it will be better to defer planting until autumn. It is possible this may not be agreeable if you are impatient and eager to begin, but you will find it more prudent. Even though the soil should have sunk during the summer months, do not be uneasy about it; on the contrary, this will be rather the better for the trees which will be planted in it. We know very well, and you have no doubt often heard it said, that one may plant at any time of the year, and do so successfully; but these unseasonable plantings require precaution, and often a considerable amount of it. To enter into particulars on this subject here would merely swell the size of these notes without enabling us to gain any time by it. We are only speaking, observe, of woody plants, and particularly of fruit trees.

Well, you have bought and brought home your trees; if your planting is of any extent it will last for some time, and you must take care that during that time the roots do not suffer from exposure. Put them "by the heels" in a trench near the planting ground, not burying them very deep, but earthing them up so as to cover the necks well. Group your trees according to their kinds and forms; have some care for all these little details, untie your plants bundle by bundle, and carefully place the proper label on each kind. These may appear too minute precautions; but they will, in the first place, facilitate the work, and, in the second, they will prevent your eating one kind of fruit under the impression that you are eating another, and they will also save you from being bewildered in a maze of mistakes which careless labelling is sure to lead to, and which it is not easy to correct afterwards.

In the next place, you have to provide a position for each tree. The ground having been already fully prepared, all you have to do is to make holes just large enough to contain all the roots easily; and, although the soil has been manured, you may throw into the bottom of each hole a little more decomposed manure, and cover it with a few inches of soil. In the meantime, moreover, the trees should have been trimmed—that is, have had the roots pruned a little, and the unsound parts removed. Then dip the roots in water, or, if their size will not allow of this, water them with a rose watering-pot; immediately afterwards cover them with well-pulverised soil.

Arrange the trees with taste and regularity, and do not place them at random, one standing to the right and another to the left. Generally, in order to have two guiding points, a tree is planted at each end of the line. That is one way; but still there is need of great care and a good eye. It is better to use a surer method: lay a cord from one end to the other; as, in digging the holes, the soil is thrown out on each side, the cord does not meet with any obstacle, and shows accurately the proper place for each tree; and, although it may not be so flattering to one's vanity as to be able to do it by the eye alone, it is sure to be correct, and that is the main thing. It is needless to say that two men at least are required to plant a tree—one to hold it in its place, and the other to cover the roots with soil. If you plant wall trees, let the graft be turned as much as possible towards the wall, so that the wound which was made in cutting off the heel may be sheltered from the sun; these wounds, moreover, are never very pretty things to look at. But, in the first and principal place, arrange the tree so that the spurs which you will have to prune by-and-by may be conveniently placed.

In planting, let the graft always be some inches above the surface, especially in the case of Apples grafted on Doucin and Paradise stocks; the colder your soil is the more closely you must look to this. If buried, the graft might root, and thus your object would be defeated. The digging and the manuring, and even the space which the roots occupy, will all have raised the ground somewhat; but that is only temporary; a subsidence will gradually take place, so that after a time the tree will be in a hollow, while if you have made allowance beforehand for the depression which will follow, your tree will settle to just where it ought to be, that is, to the level of the surrounding ground. If the soil is dry, as soon as the planting is finished, water well. In order to complete the work properly you will, about the end of March, cover the ground about the bottom of the stems with a couple of inches of half-decomposed manure.

Moles in Gardens.—I was pleased to find that the useful little animal the mole, Hount as it is called here, has at least one friend besides myself in your correspondent "B. B." Having many acres of market garden on a rich sandy soil, I find moles very useful in eradicating the large earthworm which does so much damage to the early spring crops, though I must admit it is vexatious to see the drills of young Onions, &c., ploughed out and left to perish in the sun and wind, but I always find the best crops where the mole has burrowed.—B. F.

VEGETABLES.

Chicory.—Chicory, or Succory, as it is sometimes called, does not appear to be very extensively cultivated now-a-days, a circumstance which may be accounted for by the fact that it has been supplanted by its near relative, the Endive, which, on account of its finer appearance and milder flavour, has become the greater favourite, both for market and general purposes. The Chicory possesses, however, many meritorious points, which should recommend it to more general attention than it now enjoys. It is of easy culture, is not at all fastidious as to soil, and may, therefore, be grown largely by those who cannot devote much time or attention to the culture of choice salading. Even where Lettuces and Endive are extensively grown, Chicory should find a place, as its addition to the salad bowl imparts a piquancy which cannot well be obtained by any other ingredient. It is largely used and is much esteemed as a winter salad in many parts of France, and, in common with the Dandelion, it there enjoys the reputation of possessing peculiar blood-purifying principles. It is often, however, eaten alone, and liked by those accustomed to its use. It should, however, in a general way be mixed with Lettuces or Corn salad. If seed be sown in well-cultivated land in March, good roots will be formed by autumn, which, if lifted during winter and placed in any dark cellar or Mushroom house in common soil, will soon yield good blanched heads of leaves fit for salad.

Root and Flower of Chicory.

Rosette Colewort.—There is no more delicious vegetable than the Colewort when well grown, and the great wonder is that so few take the trouble to ensure a good supply of them throughout the winter months. Seed sown in July, planting out the young plants in September, will give nice young heads by the winter large enough to do good service, but not so much turned in as to endanger their rotting. A good plan is to plant between the rows of Potatoes, pulling up the haulm of these latter before so doing. When the Potatoes are dug a little extra soil will be turned in around the stems of the Cabbages, and the stirring of the soil in taking up the Potatoes will do them good. Ground where a crop of early Potatoes has been lifted is, however, best, as it is sure to be in good, free working order. The subject of the present note is an excellent kind, of very moderate growth, and much hardier than the other varieties of this useful esculent.—J.

Rhubarb Roots for Forcing.—The best-sized roots for forcing are those about three years or four years old; they can easily be taken up and moved anywhere where a little artificial heat can be secured. Large old roots cannot be moved without a good deal of muti-

lation, which weakens the produce. With a temperature anywhere between 45° and 60° success will be certain; of course the temperature should be regular and steady; the plants should not be overheated one day and starved the next. I know a baker who always grows beautiful early Rhubarb in a shed adjoining his bakehouse; the wall of the oven abuts against the shed, and keeps up a steady heat. Strong roots may be taken up and packed in old deep boxes, baskets, or cement casks; these could be moved anywhere where warmth can be had. I always think early Rhubarb that has been grown in twilight or partial darkness is better in colour and more delicate in flavour than where fully exposed to light. When grown in an atmosphere charged with ammonia from rank manure the flavour is generally unpleasant. This, however, can always be obviated by throwing the manure into a heap, and when it heats well, turning it over, shaking and mixing it well together. This should be repeated if the manure be fresh from the stable in about a week or ten days. In places where leaves can be obtained these should always be raked up in autumn and placed in a stack for hotbed making, covering them with straw or litter, to keep the wind from blowing them about. With a supply of leaves and a little manure, to hold them together, a station for forcing Rhubarb may be made in any out-of-the-way corner. It may be either oval or round, but it should at least have a regular outline. Having decided upon the position and its size, drive in a few stout, rough stakes, 18 in. apart, leaving them, when driven in securely, about 3 ft. 6 in. to 4 ft. out of the ground. Fagg-wood or rough branches of any kind may be entwined between the stakes, so as to form a substantial wattled fence round the station; and outside, against this, the fermenting materials (leaves and manure in about equal portions in the shape of good substantial linings) should be placed. The roots of the Rhubarb should be packed nearly close together inside, and should have all the interstices filled up with fine soil. They should have a good watering with tepid water to settle them, and the top should be covered with hurdles, deeply thatched with straw, leaving a clear space of 18 in. or so between the roots and the roof. I have forced good-flavoured Rhubarb in this way without much trouble or expense. When a good supply of roots is provided, a very small amount of ingenuity will contrive some mode of forcing them. Roots that have been forced, if not gathered from too severely, if sheltered somewhere till spring, will divide into a number of crowns; and if planted out on good land, 2 ft. apart, will make excellent plants again in two or three years.—H.

A Cottager's Experience of Potatoes.—I think the remarks of "T. S." on this subject are very misleading, because he does not mention either the situation of his garden or the nature of the soil. If his soil is very heavy and retentive of wet, we may, perhaps, not be surprised that seven kinds out of nine which he mentions were bad (I presume he means diseased). But if his garden is well away from the smoke of a town, and the soil is at all suitable and in good heart, I think the varieties ought not to bear the blame, but rather the cultivator. We all know that acres of Potatoes on low, wet land have been diseased this year, but we also know that most of the soils named by "T. S." have produced fine crops in ordinary situations, and that this has really been a grand Potato year. Some persons go on growing Potatoes year after year on the same ground until it is absolutely sick of Potatoes, and no matter what variety they plant it is impossible to obtain a crop. In old gardens near manufacturing towns it is perfect folly to attempt growing Potatoes, as the ground becomes saturated with smoke and pernicious gases. As an illustration of this fact I may mention that there are numbers of gardens only 500 yards nearer to the town than mine which will not produce Potatoes worth digging, because houses are too numerous around them, whereas my neighbours and myself can grow not only good Potatoes, but Roses, our gardens being on an open hillside. If "T. S." has nothing to complain of on the score of either soil or situation, many of your readers will no doubt be curious to hear how he accounts for his failure, and also whether the seven varieties branded as bad were failures generally in the midlands.—Burns.
